U. S. DEPARTMENT OF AGRICULTURE.

Scientific Bureaus.

WEATHER BUREAU—C. F. Marvin, *Chief*.
 BUREAU OF ANIMAL INDUSTRY—A. D. Melvin, *Chief*.
 BUREAU OF PLANT INDUSTRY—W. A. Taylor, *Chief*.
 FOREST SERVICE—H. S. Graves, *Forester*.
 BUREAU OF SOILS—Milton Whitney, *Chief*.
 BUREAU OF CHEMISTRY—C. L. Alsberg, *Chief*.
 BUREAU OF STATISTICS—L. M. Estabrook, *Statistician*.
 BUREAU OF ENTOMOLOGY—L. O. Howard, *Entomologist*.
 BUREAU OF BIOLOGICAL SURVEY—H. W. Henshaw, *Chief*.
 OFFICE OF PUBLIC ROADS—L. W. Page, *Director*.

OFFICE OF EXPERIMENT STATIONS—A. C. True, *Director*.

THE AGRICULTURAL EXPERIMENT STATIONS.

ALABAMA—

College Station: *Auburn*; J. F. Duggar.^a
 Canebrake Station: *Uniontown*; L. H. Moore.^a
 Tuskegee Station: *Tuskegee Institute*; G. W. Carver.^a

ALASKA—*Sitka*: C. C. Georgeson.^b

ARIZONA—*Tucson*: R. H. Forbes.^a

ARKANSAS—*Fayetteville*: M. Nelson.^a

CALIFORNIA—*Berkeley*: T. F. Hunt.^a

COLORADO—*Fort Collins*: C. P. Gillette.^a

CONNECTICUT—

State Station: *New Haven*; } E. H. Jenkins.^a
 Storrs Station: *Storrs*; }

DELAWARE—*Newark*: H. Hayward.^a

FLORIDA—*Gainesville*: P. H. Rolfs.^a

GEORGIA—*Experiment*: R. J. H. De Loach.^a

GUAM—*Island of Guam*: A. C. Hartenbower.^b

HAWAII—

Federal Station: *Honolulu*; E. V. Wilcox.^b
 Sugar Planters' Station: *Honolulu*; H. P. Agee.^a

IDAHO—*Moscow*: W. L. Carlyle.^a

ILLINOIS—*Urbana*: E. Davenport.^a

INDIANA—*La Fayette*: A. Goss.^a

IOWA—*Ames*: C. F. Curtiss.^a

KANSAS—*Manhattan*: W. M. Jardine.^a

KENTUCKY—*Lexington*: J. H. Kastle.^a

LOUISIANA—

State Station: *Baton Rouge*; }
 Sugar Station: *Audubon Park*, } W. R. Dodson.^a
New Orleans; }
 North La. Station: *Calhoun*; }

MAINE—*Orono*: C. D. Woods.^a

MARYLAND—*College Park*: H. J. Patterson.^a

MASSACHUSETTS—*Amherst*: W. P. Brooks.^a

MICHIGAN—*East Lansing*: R. S. Shaw.^a

MINNESOTA—*University Farm, St. Paul*: A. F. Woods.^a

MISSISSIPPI—*Agricultural College*: E. R. Lloyd.^a

MISSOURI—

College Station: *Columbia*; F. B. Mumford.^a
 Fruit Station: *Mountain Grove*; Paul Evans.^a

^a Director.

^b Special agent in charge.

^c Acting director.

MONTANA—*Bozeman*: F. B. Linfield.^a

NEBRASKA—*Lincoln*: E. A. Burnett.^a

NEVADA—*Reno*: S. B. Doten.^a

NEW HAMPSHIRE—*Durham*: J. C. Kendall.^a

NEW JERSEY—*New Brunswick*: J. G. Lipman.^a

NEW MEXICO—*State College*: Fabian Garcia.^a

NEW YORK—

State Station: *Geneva*; W. H. Jordan.^a

Cornell Station: *Ithaca*; B. T. Galloway.^a

NORTH CAROLINA—

College Station: *West Raleigh*; } B. W. Kilgore.^a
 State Station: *Raleigh*; }

NORTH DAKOTA—*Agricultural College*: T. P. Cooper.^a

OHIO—*Wooster*: C. E. Thorne.^a

OKLAHOMA—*Stillwater*: L. L. Lewis.^a

OREGON—*Corvallis*: A. B. Cordley.^a

PENNSYLVANIA—

State College: R. L. Watts.^a

State College: Institute of Animal Nutrition;
 H. P. Armsby.^a

PORTO RICO—

Federal Station: *Mayaguez*; D. W. May.^b

Sugar Planters' Station: *Rio Piedras*; J. T. Crawley.^a

RHODE ISLAND—*Kingston*: B. L. Hartwell.^a

SOUTH CAROLINA—*Clemson College*: J. N. Harper.^a

SOUTH DAKOTA—*Brookings*: J. W. Wilson.^a

TENNESSEE—*Knoxville*: H. A. Morgan.^a

TEXAS—*College Station*: B. Youngblood.^a

UTAH—*Logan*: E. D. Ball.^a

VERMONT—*Burlington*: J. L. Hills.^a

VIRGINIA—

Blacksburg: W. J. Schoene.^c

Norfolk: Truck Station; T. C. Johnson.^a

WASHINGTON—*Pullman*: I. D. Cardiff.^a

WEST VIRGINIA—*Morgantown*: E. D. Sander-
 son.^a

WISCONSIN—*Madison*: H. L. Russell.^a

WYOMING—*Laramie*: H. G. Knight.^a

EXPERIMENT STATION RECORD.

Editor: E. W. ALLEN, PH. D., *Assistant Director*.
Assistant Editor: H. L. KNIGHT.

EDITORIAL DEPARTMENTS.

Agricultural Chemistry and Agrotechny—L. W. FETZER, Ph. D., M. D.

CONTENTS OF VOLUME XXX.

EDITORIAL NOTES.

	Page.
The letters and writings of Dr. S. W. Johnson.....	1
Rediscovered ideals for agricultural investigation.....	5
Progress of studies in animal nutrition.....	101
Requirements of feeding experiments.....	103
Need of redirection of experimental work in animal husbandry.....	106
The "Village Moderne" at the Ghent Exposition.....	301
The opportunity of the agricultural college for civic betterment.....	305
Journal literature of agricultural science.....	401
The essentials of a scientific paper.....	403
Functions of criticism in agricultural science.....	407
The agricultural extension act.....	601
State and National cooperation in agricultural extension.....	605
The Louisville conference on country-life development.....	608
Rural sanitation—an opportunity for extension work.....	701
ALABAMA COLLEGE STATION:	
Bulletin 174, December, 1913.....	636
ALABAMA TUSKEGEE STATION:	
Bulletin 25, October, 1913.....	19

ARKANSAS STATION:

Bulletin 115, September, 1913.....	336
Bulletin 116, January, 1914.....	533
Circular 18, July, 1913.....	534
Circular 19, September, 1913.....	657
Circular 20, December, 1913.....	739

CALIFORNIA STATION:

Bulletin 240, September, 1913.....	28
Bulletin 241.....	741
Bulletin 242, January, 1914.....	714
Bulletin 243, March, 1914.....	883
Bulletin 244, March, 1914.....	814
Circular 106, September, 1913.....	83
Circular 107, October, 1913.....	345
Circular 108, October, 1913.....	316
Circular 109, January, 1914.....	694
Circular 110, December, 1913.....	625
Circular 111, December, 1913.....	627
Circular 112, January, 1914.....	695
Circular 113, January, 1914.....	695
Circular 114, February, 1914.....	687
Circular 115, February, 1914.....	841
Circular 116, March, 1914.....	854

COLORADO STATION:

Bulletin 190, June, 1913.....	36
Bulletin 191, June, 1913.....	35
Bulletin 192, November, 1913.....	813
Bulletin 193, January, 1914.....	818
Bulletin 194, January, 1914.....	885
Twenty-fifth Annual Report, 1912.....	197

CONNECTICUT STATE STATION:

Bulletin 179, October, 1913.....	339
Bulletin 180, January, 1914.....	835
Bulletin 181, January, 1914.....	856
Bulletin 182, March, 1914.....	854
Annual Report 1913, pt. 2.....	327
Annual Report 1913, pt. 3.....	654
Annual Report 1913, pt. 4.....	664
Annual Report 1913, pt. 5.....	868

FLORIDA STATION:

Bulletin 119, November, 1913.....	55
Bulletin 120, January, 1914.....	528
Bulletin 121, February, 1914.....	648

GEORGIA STATION:

Bulletin 103, January, 1914.....	517
Circular 69, August, 1913.....	697
Circular 70, January, 1914.....	635
Circular 71, January, 1914.....	626

GUAM STATION:

Annual Report, 1912.....	17, 37, 41, 68, 94
--------------------------	--------------------

HAWAII STATION:

Page.

Bulletin 29, December 1, 1913.....	445
Bulletin 30, December 31, 1913.....	419
Bulletin 31, January 17, 1914.....	420
Bulletin 32, March 26, 1914.....	841
Annual Report, 1913.....	813, 828, 838, 841, 852, 899

HAWAIIAN SUGAR PLANTERS' STATION:

Division of Agriculture and Chemistry Bulletin 42, 1914.....	890
Division of Agriculture and Chemistry Bulletin 43, 1914.....	891

IDAHO STATION:

Bulletin 78, January, 1914.....	786
---------------------------------	-----

ILLINOIS STATION:

Bulletin 165, July, 1913.....	369, 370
Circular 169, September, 1913.....	467

INDIANA STATION:

Bulletin 167, October, 1913.....	767
Bulletin 168, November, 1913.....	769
Bulletin 169, August, 1913.....	169
Bulletin 170, December, 1913.....	518

Bulletin 9, An Economic Study of Acacias, C. H. Shinn.....	146
Bulletin 10, Progress Report of Cooperative Irrigation Experiments at California University Farm, Davis, Cal., 1909-1912, S. H. Beckett.....	34
Bulletin 11, Forest Management of Loblolly Pine in Delaware, Maryland, and Virginia, W. D. Sterrett.....	446
Bulletin 12, Uses of Commercial Woods of the United States, H. Maxwell.....	46
Bulletin 13, White Pine Under Forest Management, E. H. Frothingham.....	535
Bulletin 14, The Migratory Habit of House-fly Larvæ as Indicating a Favorable Remedial Measure.—An Account of Progress, R. H. Hutchison.....	756
Bulletin 15, A Sealed Paper Carton to Protect Cereals from Insect Attack, W. B. Parker.....	53
Bulletin 16, The Culture of Flue-cured Tobacco, E. H. Mathewson.....	39
Bulletin 17, The Refrigeration of Dressed Poultry in Transit, Mary E. Pennington et al.....	71
Bulletin 18, A Report on the Phosphate Fields of South Carolina, W. H. Waggonman.....	27
Bulletin 19, The Grape Leafhopper in the Lake Erie Valley, F. Johnson.....	547
Bulletin 20, The Management of Sheep on the Farm, E. L. Shaw and L. L. Heller.....	372
Bulletin 21, The Commercial Fattening of Poultry, A. R. Lee.....	470
Bulletin 22, Game Laws for 1913, T. S. Palmer et al.....	52
Bulletin 23, Vitrified Brick as a Paving Material for Country Roads, V. M. Peirce and C. H. Moorefield.....	86
Bulletin 24, Cottonwood in the Mississippi Valley, A. W. Williamson.....	346
Bulletin 25, The Shrinkage in Weight of Beef Cattle in Transit, W. F. Ward and J. E. Downing.....	171
Bulletin 26, American Medicinal Flowers, Fruits, and Seeds, Alice Henkel...	145
Bulletin 27, Bouillon Cubes: Their Contents and Food Value Compared with Meat Extracts and Homemade Preparations of Meat, F. C. Cook.....	162
Bulletin 28, Experiments in Bulb Growing at the United States Bulb Garden at Bellingham, P. H. Dorsett.....	145
Bulletin 29, Crew Work, Costs, and Returns in Commercial Orchardling in West Virginia, J. H. Arnold.....	144
Bulletin 30, Cereal Investigations at the Nephi Substation, P. V. Cardon.....	135
Bulletin 31, Behavior, Under Cultural Conditions, of Species of Cacti Known as Opuntia, D. Griffiths.....	336
Bulletin 32, An Example of Successful Farm Management in Southern New York, M. C. Burritt and J. H. Barron.....	193
Bulletin 34, Range Improvement by Deferred and Rotation Grazing, A. W. Sampson.....	334
Bulletin 35, Factors Governing the Successful Storage of California Table Grapes, A. V. Stubenrauch and C. W. Mann.....	345
Bulletin 36, Studies of Primary Cotton Market Conditions in Oklahoma, W. A. Sherman et al.....	193
Bulletin 37, Nitrogenous Fertilizers Obtainable in the United States, J. W. Turrentine.....	126

	Page.
Bulletin 38, Seed Selection of Egyptian Cotton, T. H. Kearney.....	138
Bulletin 39, Experiments with Wheat, Oats, and Barley in South Dakota, M. Champlin.....	434
Bulletin 40, The Mosaic Disease of Tobacco, H. A. Allard.....	450
Bulletin 41, A Farm-management Survey of Three Representative Areas in Indiana, Illinois, and Iowa, E. H. Thomson and H. M. Dixon.....	490
Bulletin 42, The Action of Manganese in Soils, J. J. Skinner, M. X. Sullivan, et al.	823
Bulletin 43, American-grown Paprika Pepper, T. B. Young and R. H. True..	343
Bulletin 44, The Blights of Coniferous Nursery Stock, C. Hartley.....	151
Bulletin 45, Experiments in the Use of Sheep in the Eradication of the Rocky Mountain Spotted Fever Tick, H. P. Wood.....	162
Bulletin 46, A Descriptive Catalogue of the Soils of Virginia so Far Identified in the Soil Survey.....	319
Bulletin 47, Lessons for American Potato Growers from German Experiences, W. A. Orton.....	139
Bulletin 48, The Shrinkage of Shelled Corn While in Cars in Transit, J. W. T. Duvel and L. Duval.....	337
Bulletin 49, The Cost of Raising a Dairy Cow, C. M. Bennett and M. O. Cooper.	472
Bulletin 50, Possible Agricultural Development in Alaska, L. Chubbuck.....	491
Bulletin 52, The Anthracnose of the Mango in Florida, S. M. McMurren.....	451
Bulletin 53, Object-lesson and Experimental Roads, and Bridge Construction, 1912-13.....	386
Bulletin 55, Balsam Fir, R. Zon.....	843
Bulletin 56, A Special Flask for the Rapid Determination of Water in Flour and Meal, J. H. Cox.....	506
Bulletin 57, Water Supply, Plumbing, and Sewage Disposal for Country Homes, R. W. Trullinger.....	690
Bulletin 58, Five Important Wild-duck Foods, W. L. McAtee.....	545
Bulletin 59, The Tobacco Splitworm, A. C. Morgan and S. E. Crumb.....	550
Bulletin 60, The Relation of Cotton Buying to Cotton Growing, O. F. Cook...	527
Bulletin 62, Tests of the Waste, Tensile Strength, and Bleaching Qualities of the Different Grades of Cotton as Standardized by the U. S. Government, N. A. Cobb.....	527
Bulletin 63, Factors Governing the Successful Shipment of Oranges from Florida, A. V. Stubenrauch et al.	841
Bulletin 64, Potato Wilt, Leaf-roll, and Related Diseases, W. A. Orton.....	649
Bulletin 65, Cerebrospinal Meningitis ("Forage Poisoning"), J. R. Mohler...	685
Bulletin 66, Statistics of Sugar in the United States and Its Insular Possessions, 1881-1912, F. Andrews.....	736
Bulletin 67, Tests of Rocky Mountain Woods for Telephone Poles, N. de W. Betts and A. L. Heim.....	843
Bulletin 68, Pasture and Grain Crops for Hogs in the Pacific Northwest, B. Hunter.....	771
Bulletin 69, Cicuta, or Water Hemlock, C. D. Marsh, A. B. Clawson, and H. Marsh.....	880
Farmers' Bulletin 561, Bean Growing in Eastern Washington and Oregon, and Northern Idaho, L. W. Fluharty.....	138
Farmers' Bulletin 562, The Organization of Boys' and Girls' Poultry Clubs, H. M. Lamon.....	395
Farmers' Bulletin 563, The Agricultural Outlook.....	392
Farmers' Bulletin 564, The Gipsy Moth and the Brown-tail Moth, with Suggestions for Their Control, A. F. Burgess.....	549
Farmers' Bulletin 565, Corn Meal as a Food and Ways of Using It, C. F. Langworthy and Caroline L. Hunt.....	557

	Page.
Farmers' Bulletin 566, Boys' Pig Clubs, W. F. Ward.....	395
Farmers' Bulletin 567, Sugar-beet Growing Under Irrigation, C. O. Townsend.	529
Farmers' Bulletin 568, Sugar-beet Growing Under Humid Conditions, C. O. Townsend.....	529
Farmers' Bulletin 569, Texas or Tick Fever, J. R. Mohler.....	884
Farmers' Bulletin 570, The Agricultural Outlook.....	593

CONTENTS OF VOL. XXX, NO. I.

Editorial notes:	Page.
The letters and writings of Dr. S. W. Johnson.....	1
Rediscovered ideals for agricultural investigation.....	5
Recent work in agricultural science.....	10
Notes.....	95

SUBJECT LISTS OF ABSTRACTS.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

Principles of agricultural chemistry, Fraps.....	10
About the pentosans, Goy.....	10
The temperature at which starch granules gelatinize, Nyman.....	10
The chemistry of the resins of the Douglas fir, Frankforter and Brown.....	10
The investigation of the chemical action of bacteria, Harden.....	10
Progress made in regard to the fermentation organisms and enzymes, Koch.....	11
In regard to the ferment nature of peroxidase, Hesse and Kooper.....	11
Cleavage of α and β methyl glucosid by <i>Aspergillus niger</i> , Dox and Neidig.....	11
Determination of alkalis in silicates with calcium chlorid, Mäkinen.....	11
New methods for the examination and judgment of soils, König.....	12
The determination of lime in cow feces, Dutcher.....	12
Water analysis for sanitary and technical purposes, Stocks.....	12
Mineral analysis of water.....	13
Food control by police officials, Bremer.....	13
Rapid method for determining fat in cacao with the Zeiss refractometer, Richter.....	13
Changes in methods for succinic and malic acids, von der Heide and Schwenk.....	13

	Page.
Studies in regard to the dry substance (total solids) of milk, Splittgerber.....	13
The conservation of samples of milk destined for analysis, Rocques.....	13
The preservation of milk samples destined for analysis, Denigés.....	14
The detection of peanut oil in olive oil, Adler.....	14
Detection of peanut oil in olive oil according to Franz-Adler method, Lüers...	14
Technical accounting and chemical control in sugar manufacture, Davoll, jr...	14
The sugar content of maize stalks, Blackshaw.....	14
Objectionable nitrogenous compounds in sugar-cane juice, Zerban.....	15
Practical results by determining injurious nitrogen in sugar beets, Friedl.....	15
Inversion of saccharose and the changes of feed beets during storage, Jekelius.	15
Manufacture of a sugar-beet flour (beet meal), and its use, Aulard.....	15
Composition of apples and pure ciders of the lower Seine regions, Brioux.....	16
Cider vinegar and its making, O'Gara.....	16
The composition of pure wine from American native grapes, Alwood.....	16
The alcohol industry of the Philippine Islands, Gibbs.....	16
The cooperative manufacture of casein, Dornic.....	16
Synthetic tannin, Chase.....	16
The effect of "lime-sulphur" spray manufacture on the eyesight, Withrow....	16

METEOROLOGY—WATER.

Syllabus on meteorological information and agricultural practice, Shaw.....	16
"Surface" climate, Balls.....	17
Meteorological conditions in a field crop, Balls.....	17
Meteorological yearbook for 1913.....	17
Temperature records, Thompson.....	17
Rain and its measurement, Dumas.....	17
Conservation of rainfall, Spillman.....	17
Surface water of South Atlantic and Gulf of Mexico basins, Hall and Pierce...	17
Geology and ground waters of Florida, Matson and Sanford.....	17
Surface water supply of Ohio River basin, 1911, Horton, Hall, and Jackson....	18
The Ohio Valley flood of March-April, 1913, Horton and Jackson.....	18
Geology and water resources of Sulphur Spring Valley, Ariz.....	18
Ground water in Boxelder and Tootle counties, Utah, Carpenter.....	18
Pollution of underground waters with sewage through fissures in rocks, Albert.	19
The sewage sludge problem and its solution, Grossmann.....	19

SOILS—FERTILIZERS.

Soils of the United States, Marbut, Bennett, and Lapham.....	19
A study of the soils of Macon County, Alabama, and their adaptability, Carver.	19
The gullied lands of west Tennessee, Purdue.....	19
The sulphur content of some typical Kentucky soils, Shedd.....	20
Analysis of coconut soils, De Verteuil.....	20
Some Libyan soils, Maugini.....	20
The alkaline soils in Egypt and their treatment, Mosséri.....	21
The movements of soil water in an Egyptian cotton field, Balls.....	21
The water balance and losses of plant food in soils, von Seelhorst et al.....	21
A new method of measuring the capillary lift of soils, Lynde and Dupré.....	22
Efficiency of soil constituents as semipermeable membranes, Lynde and Dupré.	23
Action of hydroxyl ions on clay soils in connection with marling, Rohland....	23
The properties of so-called soil zeolites, Blanck.....	23
Factors in the maintenance of permanent fertility of the soil, Fippin.....	23
Agricultural utilization of acid lands by acid-tolerant crops, Coville.....	23
Formation of nitrates in soil after freezing and thawing, Lyon and Bizzell....	23
The accumulation of green manure nitrogen in sandy soils, von Seelhorst et al.	24
Manures and fertilizers, Wheeler.....	24
Experiments with fertilizers, manure, lime, and floats, Thorne and Mohn.....	25
The preservation of cattle manure.....	25
The effects of fertilizers other than that of adding plant food, Van Slyke.....	26
The nitrogen content of night soil from the city of Florence, Passerini.....	26
Tests of the nitrogen of "Poudro," de Molinari and Ligot.....	26
Production of artificial fertilizers from nitrogen of the air, Bencke.....	26
How can the dusty condition of lime nitrogen be lessened? Stutzer.....	26
Decrease of available phosphoric acid in mixtures with cyanamid, Brackett et al.	26
Fertilizer analysis, Mitscherlich and Simmermacher.....	26
A report on the phosphate fields of South Carolina, Waggaman.....	27

	Page.
Thomas slag, its preparation and use, Wagner.....	27
Analyses of Thomas slag from different sources, von Feilitzen and Lugner.....	27
Kelp and other sources of potash, Cameron.....	27
Lime, Hite.....	27
On the influence of the ratio of lime to magnesia on plants, Loew.....	27
Is silica an indispensable constituent of plant food? Lundie.....	27
Commercial fertilizers, Burd.....	28

AGRICULTURAL BOTANY.

On the chemical organization of the cell, Ruhland.....	28
Significance of character of electrical charge for passage of colloids, Ruhland.....	28
Fermentation of some cyclic series compounds and formation of humus, Perrier.....	28
Necessity of bacterial association for <i>Chondromyces crocatus</i> , Pinoy.....	28
A mud sucking device for obtaining soil microflora and microfauna, Perfyl'ev.....	28
Studies in Indian tobaccos.—III, Inheritance in <i>Nicotiana tabacum</i> , Howard.....	29
Flowering of <i>Geranium robertianum</i> under various physical conditions, Stäger.....	29
Relation between tuberization and infestation by endophytic fungi, Beau.....	29
Influence of radioactivity on vegetation, Vacher.....	29
Some recent studies on germination, Lehmann.....	30
Germination of potato, Couvreur.....	30
Transpiration and osmotic pressure in mangroves, von Faber.....	30
The distribution of temperature in living plants, Dupont.....	30
Wind and the plant world; a study, Kroll.....	30
Presence and persistence of hydrocyanic acid in grains in hot regions, Raybaud.....	30
Demonstration and localization of nitrates and nitrites in plants, Klein.....	30
Assimilation of nitric acid and deposit of manganese in plants, Houtermans.....	30
Significance of deposits in plants in solutions of manganese salts, Acqua.....	31
Deposits in plant tissues due to culture in manganese nitrate solution, Boselli.....	31
Influence of nitrates on toxicity toward fungus spores, Hawkins.....	31
The action of sodium sulphate as affecting growth of plants, Haselhoff.....	31
Atmospheric impurities near an industrial city, Crowther and Steuart.....	32
Influence of tar, particularly tarred streets, on vegetation, Claussen.....	32

FIELD CROPS.

Study of farm practice versus field experiments, Spillman.....	32
Determination of probable error in field experiments, Harnoth.....	32
Determinations of probable errors in field experiments, Alexandrowitsch.....	33
Determination of probable errors in field experiments, Harnoth.....	33
Methods of testing varieties, Kostecki.....	33
Variety tests of field crops, Lemmermann et al.....	33
Electroculture, Escard.....	33
Observations on some new methods of growing cereals, Remy and Kreplin.....	33
Dominant and recessive characters in barley and oat hybrids, Thatcher.....	33
[Fertilizer experiments], de Jong.....	34
Cooperative irrigation experiments at Davis, Cal., 1909-1912, Beckett.....	34
The reseedling of depleted grazing lands to cultivated forage plants, Sampson.....	35
A note on two textile plants from the Belgian Kongo, Mestdagh.....	35
Alfalfa seed production, Blinn.....	35
Alfalfa management in Iowa, Hughes.....	36
Experiments with Turkestan alfalfa in Hungary, Garfias.....	36
A new two-rowed winter barley, Neumann.....	36
A mutation in a pure line of <i>Hordeum distichum</i> , Kiessling.....	36
Variation studies in brome grass, Keyser.....	36
On the presence of hydrocyanic acid in white clover, Mirande.....	36
Silver King.—A corn for northern Iowa, Hughes.....	37
Corn culture in North Carolina, Burgess.....	37
Notes on corn growing in Guam, Thompson.....	37
Twelfth report of Indiana Corn Growers' Association, edited by Christie.....	37
Fourth annual report of the Ontario Corn Growers' Association, Duff.....	37
Rubelzul cotton: A new species of <i>Gossypium</i> from Guatemala, Lewton.....	37
The cotton of the Hopi Indians: A new species of <i>Gossypium</i> , Lewton.....	37
Experiments on the retting of flax, Ringelmann.....	37
Potassium fertilizer for hops, Neumann.....	37
Seed varieties of <i>Lupinus angustifolius</i> and <i>L. luteus</i> , Kajanus.....	38

	Page.
African manioc, Henry, Yves, and Ammaan.....	38
Vegetative experiments with 88 varieties of oats, Schneider.....	38
Breeding and seed production of the Fichtel Mountain oats, Raum.....	38
Wild plantain fiber from India.....	38
Variety [and manurial] tests of potatoes, Dacy.....	38
Pointers on the growing and selection of types of eating potatoes, Schiffan.....	39
Experiments in the defoliation of sugar beets, Strohmer, Briem, and Fallada..	39
Small beet seed, Briem.....	39
The size of the seed ball of beets, Plahn-Appiani.....	39
The value of bees to seed beet growing, Vasilieff.....	39
The manuring of sugar cane at Samalkota, 1902-1912, Hilson.....	39
The culture of flue-cured tobacco, Mathewson.....	39
The Utelo, a plant with oleaginous seeds, Mestdagh.....	39
On the selection of a type of wheat resistant to severe winters, Kolkunov.....	40
Portuguese varieties of wheat and their improvement, Klein.....	40
Clover and grass seeds, Boerger.....	40
Seed tests, Hiltner et al.....	40

HORTICULTURE.

Garden farming, Corbett.....	40
Pomology, horticulture, and viticulture, Reimers.....	40
Report of field work by the horticultural department during 1911, Dacy.....	40
[Fruit trees in Paraguay], Bertoni.....	41
Wild fruits of Paraguay, Bertoni.....	41
The pubescent-fruited species of <i>Prunus</i> of the Southwestern States, Mason...	41
Fruit variety tests on the Southern Utah Experiment Farm, Ballantyne.....	41
Orchard notes, Thompson.....	41
Fruit for exhibition, Batchelor.....	41
Box packing of apples, Palmer.....	41
Packing Indiana apples, Palmer.....	41
Cold storage for Iowa-grown apples, Greene.....	41
The American peach orchard, Waugh.....	42
Maurer's gooseberry book, Maurer.....	42
The practice of grape growing.—I, The technique of grape grafting, Wanner...	43
Influence of various grape stocks on the harvest, Faes and Porchet.....	43
The sexual elements of grape hybrids, Gard.....	43
Variability of the coffees grown in the Dutch East Indies, Cramer.....	43
First reports on selection tests of Robusta coffee, Van Hall.....	43
On the tarring of pruning-wounds in tea plants, Bernard and Deuss.....	43
Tea manuring experiments, Bernard and Deuss.....	43
<i>Leucæna glauca</i> as a green manure for tea, Bernard.....	43
Individual variation in the alkaloidal content of belladonna plants, Sievers...	44
Rose geranium culture, Charabot and Gatin.....	44

FORESTRY.

Forestry, Hausrath.....	44
Forestry, Kostlan.....	44
Logging, Bryant.....	44
Work of the Dominion Forestry Branch, Campbell.....	44
[Report of the] committee on forests, Leavitt et al.....	45
Forest policy of British Columbia, Ross.....	45
Avondale Forestry Station, Forbes.....	45
Report on forest statistics of Alsace-Lorraine.....	45
The sun energy in the forest, Wagner.....	45
The influence of aquatic mediums on the roots of trees, Bondoïs.....	45
Florida trees, Small.....	45
The forests of the Far East, Hofmann.....	45
Some Douglas fir plantations.—II, Cochwillan wood, North Wales, Thomson...	46
The structure of the wood of East Indian species of <i>Pinus</i> , Groom and Rushton..	46
The kapok trees of Togo, Ulbrich.....	46
The "wood-oil" trees of China and Japan, Wilson.....	46
Tagua, vegetable ivory, Albes.....	46
Uses of beech, birches, and maples, Maxwell.....	46
The wood-using industries of Iowa, Maxwell and Harris.....	46
Forest products of Canada, 1912, Lewis and Boyce.....	46
To get long life from untreated timber in trestles.....	47

DISEASES OF PLANTS.

	Page.
Smut diseases of cultivated plants, their cause and control, Güssow.....	47
Further cultures of heteroecious rusts, Fraser.....	47
Contributions on fungus diseases of plants appearing in 1912-13, Riehm.....	47
Diseases of agricultural crops, 1912, Lind, Rostrup, and Ravn.....	47
Work of phytopathological section of station in Stockholm, 1912, Eriksson.....	47
Work of the observatory of phytopathology in Turin, Voglino.....	47
Plant diseases, Davy.....	47
Some fungi parasitic on tropical plants, Griffon and Maublanc.....	48
Fungus diseases of potato in Australia and their treatment, McAlpine.....	48
Bacterial disease of potatoes, Osborn.....	48
Biology of potato plant with particular reference to leaf roll, Reitmaier.....	48
Recent researches as to the cause of potato leaf roll, Sorauer.....	48
The persistence of the potato late-blight fungus in the soil, Stewart.....	49
Does winter kill potato blight in the soil? Hall.....	49
Potato-spraying experiments in 1911, Giddings.....	49
Ufra disease of rice, Butler.....	49
Notes on scorch disease of sugar cane, Ashby.....	49
Rangpur tobacco wilt, Hutchinson.....	50
Diseases of the tomato in Louisiana, Edgerton and Moreland.....	50
Apple leaf spot.....	50
Peach leaf-curl fungus: Further tests with copper compounds, Quinn.....	50
Comparative experiments with sprays against leaf cast of grape, Bretschneider.....	50
A disease of cacao trees due to <i>Lasio diplocladia theobromæ</i> , Berthault.....	50
Nematode worms and mottled leaf, Hodges.....	51
Two fungi as causal agents in gummosis of lemon trees in California, Fawcett.....	51
Two fungus parasites of <i>Agathis grandiflora</i> , Foex.....	51
The structure and systematic position of <i>Mapeia radiata</i> , Maire.....	51
A new species of <i>Endothia</i> , Petri.....	52
More on black canker of chestnut in reply to L. Petri, Briosi and Farneti.....	52
Critical considerations on black canker of chestnut, Petri.....	52
Three undescribed heart rots of hardwood trees, especially of oak, Long.....	52

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Principles of economic zoology, Daugherty.....	52
Game laws for 1913, Palmer, Bancroft, and Earnshaw.....	52
Bibliography of Canadian zoology for 1911, Lambe.....	52
Bibliography of Canadian entomology for 1911, Hewitt.....	52
Forty-third annual report of the Entomological Society of Ontario, 1912.....	52
Insects of the year in British Columbia, Cunningham.....	53
Unusual insect attacks on fruit trees and bushes in 1912, Theobald.....	53
Report of economic zoology for the year ending September 30, 1912, Theobald.....	53
A sealed paper carton to protect cereals from insect attack, Parker.....	53
Spontaneous septicemia in the cockchafer and silkworm, Chatton.....	53
The coccobacilli infections of insects, Picard and Blanc.....	54
Locust bacterial disease, Lounsbury.....	54
Fungus diseases of scale insects and white fly, Rolfs and Fawcett.....	55
A study of caprification in <i>Ficus nota</i> , Baker.....	55
A systematic outline of the Reduviidae of North America, Fracker.....	55
The British species of the genus <i>Macrosiphum</i> , I and II, Theobald.....	55
Report of the entomologists, Rumsey and Pears.....	55
The so-called aerostatic hairs of certain lepidopterous larvæ, Riley.....	55
The parthenogenesis and oviposition of the potato tuber moth, Picard.....	55
The Phoridae in the United States National Museum, Malloch.....	56
New genera and species of muscoid flies from South America, Townsend.....	56
<i>Merodon equestris</i> in southern British Columbia, Norman.....	56
The southern corn rootworm, or budworm, Webster.....	56
The western corn rootworm, Webster.....	56
The coconut leaf-miner beetle, <i>Promecotheca cumingii</i> , Jones.....	56
The occurrence of a cotton boll weevil in Arizona, Pierce.....	56
Life history of <i>Otiorynchus ovatus</i> , Treherne.....	58
Annual report of the Bee-Keepers' Association of Ontario, 1912.....	59
The Bombidae of the New World, II, Franklin.....	59
Studies in the wood wasp superfamily Oryssioidea, with new species, Rohwer.....	59
A study in insect parasitism, Webster.....	59

	Page.
A revision of the Ichneumonidæ, with new genera and species, Morley.....	59
Descriptions of new Hymenoptera, V, Crawford.....	59
Descriptions of new family, genera, and species of ichneumon flies, Viereck...	59
Notes on sawflies, with descriptions of new species, Rohwer.....	60
The life history of <i>Ixodes angustus</i> , Hadwen.....	60

FOODS—HUMAN NUTRITION.

The municipal abattoir, Allen and McFarlin.....	60
Emaciation in meat inspection, Grüttner.....	61
Succinic acid in meat extracts and in fresh meat, Einbeck.....	61
Muscle extractives.—XIV, Carnosin and carnosin nitrate, Gulewitsch.....	61
Muscle extractives.—XV, In horseflesh, Smorodinzew.....	61

EXPERIMENT STATION RECORD.

VOL. XXX.

JANUARY, 1914.

No. 1.

Not to know something of the history of one's specialty is to miss much of the intimate and sympathetic feeling toward it which comes through acquaintance. Not to know the toilsome and often disheartening path along which the science of agriculture traveled in its early days in this country is to lack, not only an intelligent appreciation of what has actually been accomplished in a half century, but an insight into the manner in which it came about. It is to miss much of the broader interest of the subject, and much of the pride and satisfaction in its pursuit.

For the young man especially such an insight is a part of education and preparation for this field. It helps to give a proper attitude and sense of proportion, as well as enable just estimates. It is not necessary to live in the past to enjoy familiarity with it or to trace the unfolding and development of a new idea; and the man who devotes some attention to it is in no sense pursuing a dead subject. While he is broadening his sympathies and acquaintanceship he is strengthening his own grasp and conception. Not infrequently the lack of originality is disclosed of some things cherished as new, and again the relatively small advancement which has been made in some lines is brought forcibly home.

The lives of the leading pioneers in this field contain much that is of interest and worthy of knowing. To know them and their environment more intimately increases respect for what they did and for the ideals they stood for and strove to propagate. Naturally they did not fully attain to these ideals, else their work and influence would not have been so potent and we would not be where we now are, for the man who overtakes his ideals ceases to be a factor in progress. Ignorance is prone to judge these early workers unfairly by what they did not do, and to underestimate the true nature of their service, because it overlooks the hindrances that stood in their path, and has no intelligent realization of the determination, the self-supplied encouragement, and the personal effort which their work represents. It is knowledge of the environment that enables a true perspective.

The history of the movement which has brought science to the aid of agriculture has not been written, and its records are fragmentary and disconnected. Hence each effort in that direction is a welcome contribution.

The letters and papers of the late Dr. Samuel W. Johnson, for many years director of the Connecticut State Station, have recently been brought together and published by his daughter, in a volume of much historic interest. The preservation and publication of this material is a matter for congratulation, and its editor has placed her readers under many obligations for the interesting and highly instructive volume she has produced. It pertains to a period whose participants are rapidly passing and mostly gone.

The book is at once a biography of a man and a history of a movement. As a biography it is most satisfactory and entertaining, the remarkable extent to which Dr. Johnson's private and official correspondence was preserved giving an intimate view of the man and his work rarely possible. The interpolations and explanatory matter supplied by the editor serve to make the volume in a large degree a connected and faithful record of the progress of events in bringing science to the benefit and protection of the farmer.

The letters cover the period from 1848, when the interest of the schoolboy in agricultural matters and in chemistry were crystallizing and his aspirations being put on paper, to near the close of his life. They include correspondence with his intimate friend Dr. F. H. Storer of Bussey Institution, with Dr. Evan Pugh, a fellow student at Leipsic, who afterwards went to the new Pennsylvania State College, with Mr. Luther Tucker of Albany, editor of the *Country Gentleman*, who lent much encouragement to Dr. Johnson's ambitions, Dr. G. C. Caldwell of Cornell, Dr. E. W. Hilgard of California, Dr. George H. Cook of New Jersey, Dr. Peter Collier, later of the Geneva Station, Dr. Charles W. Eliot of Harvard, President W. S. Clark of Massachusetts, Sir John Lawes, Julius von Liebig, and many other notable persons.

These letters present a striking illustration of the slowness with which the idea that science has a vital and practical value to agriculture took hold in this country, and show how difficult it was to secure encouragement or support for a career in that field a half century ago. After he had determined to enter it Mr. Johnson went to Yale in 1850 and again in 1852, teaching in the meantime to acquire funds, and spent the years from 1853 to 1855 in advanced study abroad. During this time he attracted attention to himself by his writings on agricultural matters, in which he strongly presented by word and illustration the benefits to be derived from agricultural investigation and the desirability of public provision for it. Mr. Tucker was anxious to

see a place made for him in New York, and there was correspondence about positions elsewhere, but no opening presented itself on his return and he was obliged to accept a teaching position at the new Yale Scientific School, affording no direct agricultural connection. He considered the plan of opening an agricultural school, and at one time corresponded with Pugh with reference to associating him with the project, as opportunities for developing agricultural work did not materialize.

In 1855 the New York State Agricultural Society, largely through Mr. Tucker, proposed to fit up a laboratory and invited him to become its chemist. It was explained, however, that the office carried no remuneration excepting the fees for agricultural analyses, etc., which with writing for the press it was suggested "might yield a living compensation." This society was probably the first to take such an advanced step, but the outlook was not sufficiently encouraging and Dr. Johnson temporarily rejected it. Later he made an effort through the society to secure an endowment for an experiment station in that State, but this failed of support, as did the movement for an agricultural college in New York in which he hoped to have a part.

It is interesting to note in this connection that Liebig, under whom Dr. Johnson had studied in Munich, strongly considered coming to this country if he could receive suitable encouragement. A correspondent wrote in 1856: "He has almost made up his mind to go to the United States and set up a model farm and agricultural school, provided one of the States will furnish him with the lands and funds."

Meanwhile, although much occupied with his duties as instructor in chemistry at Yale, Dr. Johnson found time for some agricultural analysis and wrote a series of articles for an agricultural paper which served to introduce him to the State Agricultural Society, and resulted in his being appointed chemist to the society in 1856. This gave him an affiliation and a constituency, but quite limited opportunity. It was not until twenty years later that he realized the dream of his youth, and as the head of the sole American experiment station was able to center his efforts on agricultural work.

All through the writings of these earlier years we get glimpses of a longing for the opportunity to give himself largely to agricultural research. "It is a source of deep and continual regret," he writes, that his efforts in the field of agriculture "have been mostly confined to editing and communicating the results of the labors of others." In the preface to his book on *How Crops Grow*, in 1870, he offered an apology "for being a middleman and not a producer of the priceless commodities of science," which position he attributed to lack of opportunity.

Fertilizer inspection and fertilizer control naturally figured conspicuously in the early agricultural work. The use of fertilizers was rapidly coming into practice in the early fifties. They were not always intelligently made, for not very much was known of values, and the claims put forth for them were often exorbitant as well as their cost. Here many farmers felt a real need for assistance.

Dr. Johnson began discussing these matters in the agricultural press in 1853, while yet a student at Yale. He iterated and reiterated the necessity of chemical analysis as the only basis for judging of the composition of a fertilizer, the reliability of accurate analyses as a guide to values, and the importance to the community of a regular system of analysis of all commercial fertilizers as a safeguard against fraud as well as against the self-deception of ignorance. In 1856 he introduced the method of calculating the "valuation" per ton on the basis of the commercial values of the constituents, in the principle of which he was a strong believer.

His systematic inspection of fertilizers dated from his appointment as chemist to the State Board of Agriculture in 1856. In his first report he said: "It is vastly pleasanter to suppose that frauds are mistakes rather than willful attempts to cheat; but it is of the utmost importance to know whether we are liable to be intentionally as well as accidentally imposed upon." The condition of the trade at that time is illustrated by the statement in this first report that "of all the superphosphates I analyzed last year not one came up to a reasonable standard of quality," and "of all the other high-priced manufactured manures which have been twice analyzed not one has maintained a uniform composition."

It is difficult at the present time to realize the novelty of the undertaking. The rights of business men to make and sell what they chose in any line was undisputed, and the public was without protection except at individual expense. The principles he announced were new to business generally, and as applied to fertilizers they were largely new to many of the manufacturers as they were to the public. They subjected him to criticism and misrepresentation on the one hand, and brought him encouragement and support on the other. In 1869 Dr. George H. Cook, of New Jersey, wrote him: "The circulation of such reports as that of yours on fertilizers will be of great use, and I hope you will be allowed to continue making full and fearless reports on the worthless manures which are so common in the market." Many others, including practical farmers, expressed their appreciation and hope that he would not be stifled in his efforts. Fortunately he was able to maintain his position. His work brought inquiries from all parts of the country.

Very naturally from the interest surrounding this subject, the agitation for experiment stations, and especially the first station in Con-

necticut, was bound up with the history of fertilizer inspection. It furnished a stimulus, and in some instances overshadowed all other purposes of such an institution. One of the men most instrumental in securing the new station is quoted as intimating that "the purpose of this station was for the analysis of commercial fertilizers alone;" and the sentiment is further shown by the resolutions of a farmers' club, which stated substantially that they would patronize no manufacturer or dealer who was not willing to put his wares under the control of such an institution.

These views were not in accord with Dr. Johnson's ideas as to the full function of an experiment station or the methods of exercising a fertilizer control. He opposed any attempt on the part of the station to formally control the output of manufacturers or storehouses, but held the most effectual plan to be the taking of samples of the goods as offered for sale, and making the analyses public. This will be recognized as the form which ultimately prevailed and has been generally adopted.

It is interesting to read, at this period, of systematic work among farmers akin to some of the present features of extension work. In 1859 Dr. Johnson wrote, "I am on a month's tour among the farmers of Connecticut and expect to speak every evening of the week except Saturday and Sunday." In the following year he took prominent part in a course of agricultural lectures at New Haven, arranged by Prof. J. A. Porter, which fully five hundred persons came to New Haven to attend,—a forerunner of the short courses. He wrote many popular articles for the agricultural press, and through the columns of a leading New York daily he reached a wide audience in the early seventies, his articles and discussions of agricultural matters attracting attention from the first.

The high character of Dr. Johnson's scientific ideals and standards, and his advanced conceptions of the kind of work of most permanent value to agriculture, as shown by his earlier writings, are especially worthy of note. Although these could not be fully carried out, on account of conditions of the times, they were in evidence notwithstanding, and they served to give him a recognized leadership in agricultural thought. The passage of years brings out more clearly the advanced position which he occupied. His writings of sixty years ago are interesting reading and entirely applicable to-day. Their obscure publication has hidden them. The pity is that we haven't long ago had the benefit of the light they shed.

Early in his career, before he had entered college, in a contribution to an agricultural paper he made a plea for "reason and labor without prejudice" in scientific work: "It becomes," he said, "the interest as well as the duty of him who would bring science to the aid of agriculture to make every labor as complete as possible, and especially

to avoid the dogmatic introduction or support of untested theories, and the narrow-minded ignorance which entertains the possibility of making any one discovery which shall remedy the failings of the present practice,"—good advice for the present day, and still needed.

In an article in the *Country Gentleman* in 1854, he declared that "what agriculture most needs is the establishment of its doctrines—not the proposition of fancies, or of facts which hold good for this or that township, but the evolution of a general theory applicable everywhere. . . . The basis of doctrine will not rapidly unfold itself. It must be unfolded. If agriculturists would know, they must inquire. The knowledge they need belongs not to revelation but to science, and it must be sought for as the philosopher seeks other scientific truth." Some of this sounds quite modern. As he well realized, the method and essentials of agricultural investigation are only different in kind and not in nature from those in other branches of inquiry. We have had to learn this, and the expensive lesson that short cuts are disappointing. Much of the purely local testing and experimenting is now recognized as extension instead of investigation.

In 1856 Dr. Johnson delivered a lecture before the New York State Agricultural Society, on *The Relations Which Exist Between Science and Agriculture*. This is a truly remarkable address, which deserves to be preserved but had been largely lost to the present generation until brought to light by the publication of this volume. It foreshadowed the spirit as well as the method and the position of the agricultural experiment station.

In this address he explained why up to that time agriculture had not profited from the applications of science to the same extent that the manufacturing arts had. Aside from the inherent difficulty of the subject, one reason was "the lamentable circumstance that our agriculture is so barren of facts—I mean that kind of facts which only can form the foundation of science; I mean complete facts. . . . The first thing to be done is to multiply facts." And he outlined the way in which these scientific facts were to be acquired, in a manner so sound and clear that they are worth quoting at this time.

The establishment of facts, he explained, "is accomplished by observation and experiment. Ordinary observation takes cognizance of what transpires in the usual course of nature. Experiment is that refined instrument of modern research which interferes with the ordinary course of nature, and compels her to unusual manifestations." But experiment requires skill and direction, and keenness of perception. The great secret, as he said, is to know where to look. "The empiric experiments at a venture, without any probability to guide him. His haphazard trials often reveal new facts, but he rarely contributes largely to scientific progress because he makes haphazard experiments, because he does not reason.

"The philosopher experiments with an object in view, and distinctly in view. . . . He first collects and collates all the facts known with regard to it. He then seeks to construct a consistent explanation of these various facts. It may be that he finds it impossible to do this. Then he must verify the facts; perhaps some are false or he sees them from an insufficient point of view, or he must collect more of them by extending his observations, it may be by experiment. He shortly is enabled to form a hypothesis, to frame a theory which promises to account for the facts. Yet it is not a hypothesis but truth he seeks, and now he begins to test his theory. Every deduction which he can draw from it must prove true, else the theory is false. He therefore unites the conditions which his theory indicates will produce a given prevised result. If the result follow, his theory is confirmed, otherwise it must be rejected and a new one formed and similarly proved. Here is where experiment assumes its chief dignity and value. Here it must be suggested by reason or it can not be expected to answer any good purpose. Here if rationally devised and skillfully executed it must reveal a truth, and though the truth be negative it is not the less valuable, for every new negative result limits within narrower bounds the space wherein positive truth is to be sought."

This description leaves little to be added. It shows how deep was his insight into the method of science and how thorough his preparation for investigation in it some twenty years before the first station was achieved.

As to the requirements of experimental work in order to make it of value, Dr. Johnson mentions that at that time (1856) several experimental farms had been established in the country, but states the results of their experiments had no general or permanent worth, for "they have not been made with more insight, nor have they been calculated to clear up more doubts, than the single experiments carried out here and there by private individuals." Although executed with more care, "this has been so much more labor lost," for "the large share of the problems that are now needing solution require the laboratory and farm to unite their resources. . . . As mere practice is deficient in all that belongs to the province of science to suggest, so science alone lacks that which practice is naturally fitted to supply; each is the complement of the other; rational agriculture is the result of their union." He described the European experiment stations as "intended to make science practical and practice scientific."

The essentials and distinctions here outlined so clearly had to be learned by the American stations at heavy cost after the system was established more than thirty years later.

In a later article Dr. Johnson gave this rule for testing theories: "The best method of attaining truth is to endeavor earnestly but hon-

estly to disprove what appears to be true. . . . The only way to be certain you have got at the truth is to go counter to the current of self-complacency. If you can sit down deliberately with your supposed facts and with your theories, and try by every imaginable test to find where they do not harmonize or where they do not satisfy strict logic, then and not until then can you be pretty certain that you stand fair and square on that subject." And he adds that it is not the novelty or the glory of discovery, but the genuineness of discovery, that is of first importance!

But although Dr. Johnson had these high standards for agricultural investigation and realized the great need for work of such permanent character, he did not let this stand in the way of his usefulness. He was wise enough and zealous enough to patiently set his hand to what he could secure interest and support for, and hence in the early days much of his work was the routine analysis of fertilizers and other materials—work which needed to be done at that period and which served to develop confidence and support for other lines and for larger undertakings.

An interesting sidelight on the times and showing his genuine concern for the farmers' welfare is his caution to them, as early as 1854, against too blind confidence in all that was recommended in the name of science. "Let him beware of false lights which are nowadays hanging out in abundance; let him beware of taking advice from two dangerous characters—the conceited farmer who knows a little science, and the officious philosopher who knows a little farming." Combating the popular notion of the great value of soil analysis as a guide to the farmer, he sums up the case thus: "Soil analysis at best is a chance game; and where one wins a hundred may lose. A soil analysis is always interesting, often valuable, rarely economical."

A little later he admonished the farmers of his State to beware of setting experience in opposition to scientific truth, and in order that what he wrote might be read he headed the article "American Guano." Contrasting experience and science he declared with emphasis that there is no antagonism between the two except in error, experience being "many times unsuspecting, blind, or prejudiced." "Science is but another and the true name for all that is good in the experience of all men. . . . Common experience is the native rank but wild growth of knowledge. Science is its trained and cultivated development."

At the present day agricultural education is emphasizing these truths, and is making common experience more reliable, because more enlightened and less "unsuspecting, blind or prejudiced."

A recent writer has said that unless the student or investigator of scientific problems has in his conception some infusion of the divine

fire, his work never rises above the humdrum and the commonplace. "He *must* at times feel his heart burn within him as he walks the ways of his chosen calling." No one can read the letters and the papers of Dr. Johnson without realizing that he had the infusion of divine fire, and that many times his heart must have burned within him with zeal for his chosen subject.

But it took a man of more than enthusiasm to write as he did of the future of the agricultural experiment station and its far-reaching influence. It required vision and conviction to labor patiently for its coming, and to contend that the discovery of the new would vitalize the old in agriculture, would broaden the intellectual life of the farmer, replace mechanical actions and prejudice with reason, and bring the farmers and the agricultural colleges closer together—prophesies which he lived to see fulfilled.

It would be a careless reader who did not gain from these writings a clearer insight, a higher purpose, and an enthusiasm for a kind of work that shall endure. They carry an inspiration and a stimulus for the rising investigator, not only to continue the work of agricultural investigation, but to make the most of the larger opportunity to attain the ideals which he propagated at that early period.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

Principles of agricultural chemistry, G. S. FRAPS (*Easton, Pa., and London, 1913, pp. 493, figs. 94*).—This book is adapted for the uses of the student and those wishing an introduction to the field of agricultural chemistry, as well as for a reference book. It is plentifully illustrated with reproductions of photographs taken chiefly from experiment station literature and that of the United States Department of Agriculture. Considerable attention is given to the chemistry relating to problems of both plant and animal physiology.

The chapter headings are as follows: Essentials of plant life; the plant and the atmosphere; origin of soils; physical composition and classes of soils; physical properties of soils; the soil and water; chemical constituents of the soil; chemical composition of the soil; active plant food and water-soluble constituents of the soil; chemical changes; soil deficiencies; losses and gains by the soil; manure; sources and composition of fertilizers; purchase and use of fertilizers; constituents of plants; composition of plants and feeds; digestion; utilization of food; maintenance ration and fattening; feeding work animals and growing animals; feeding milk cows; and feeding standards and feeding.

About the pentosans, S. GOY (*Fühling's Landw. Ztg.*, 61 (1912), No. 18, pp. 606-612).—A discussion in regard to the chemistry and biology of pentosans and their occurrence in nature.

The temperature at which starch granules gelatinize, M. NYMAN (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 24 (1912), No. 11, pp. 673-676, figs. 8).—The temperature at which starch does not affect polarized light is looked upon as the gelatinization point. For rye starch it was found to be 57° C., for barley starch 58°, and for wheat starch 59°.

The chemistry of wood.—**The resins of the Douglas fir**, G. B. FRANKFORTER and H. H. BROWN (*Orig. Commun. 8. Internat. Cong. Appl. Chem. [Washington and New York]*, 25 (1912), Sects. I-Ve, p. 359).—An acid which the authors chose to call betic acid was isolated from the resin obtained from the wood of the Douglas fir. When it was recrystallized from 62 per cent alcohol, it appeared as well-formed crystals with a melting point of from 143.5 to 144.5° C. The figures obtained on elementary analysis pointed to the formula $C_{17}H_{24}O_2$, which was verified by the analyses of its salts and by its neutral equivalent. "Molecular weight determinations by the freezing point method, however, gave numbers nearly twice too high for the above formula, doubtless a result of polymerization. In addition to the preparation of the metallic salts, bromin and iodine compounds were made and studied." The molecular constitution is regarded as still undecided.

The investigation of the chemical action of bacteria, A. HARDEN (*Chem. World*, 1 (1912), No. 12, pp. 403, 404).—A review of work by various investigators as to the bacteria which are hygienically and industrially important. The changes brought about by bacteria are regarded as principally due to the enzymes which they contain or elaborate.

Progress made in regard to the fermentation organisms and enzymes, A. KOCH (*Jahresber. Gärungs-Organ.*, 20 (1909), pp. VIII+659).—This is a retrospect of the work published during 1909, including text-books, etc., (pp. 1-17); methods and apparatus (pp. 18-47); morphology of yeasts and bacteria (pp. 48-84); general physiology of bacteria (pp. 85-188); special kinds of fermentations such as alcoholic, lactic acid, and those in cheese and milk; utilization of atmospheric nitrogen, nitrification, etc. (pp. 189-487); and enzymes (pp. 488-630).

In regard to the ferment nature of peroxidase, A. HESSE and W. D. KOOPER (*Ztschr. Untersuch. Nahr. u. Genussmit.*, 24 (1912), No. 5, pp. 301-309).—A discussion of Grimmer's statements in regard to peroxidase (E. S. R., 27, p. 803) is followed by the results of some experiments relative to the nature of peroxidase in milk.

It is shown that the reaction, when brought into contact with certain reagents, e. g., Rothenfusser's, Storch's, or Arnold's, in the presence of hydrogen peroxid, is due to the catalytic action of iron compounds present in milk. A solution containing less iron (0.004 per cent) than reprecipitated albumin contains produced a marked reaction with Arnold's and Rothenfusser's reagents.

The reason that milk loses its activity after being boiled is the denaturizing of the compounds giving the peroxidase reaction. Lactic acid, sodium thiosulphate, and ethyl, methyl, and amyl alcohols destroy or inhibit the appearance of the peroxidase reaction in milk. The same inhibition was noted when the various chemical substances were added to a solution of iron lactate, which, under ordinary conditions in the presence of hydrogen peroxid will give the same reaction as milk.

Mercuric chlorid and chloroform, two pronounced enzym poisons, do not visibly affect the appearance of the reactions in either the iron solution or milk. Rothenfusser's reaction can be stimulated to greater intensity by other substances present in milk, such as alkali phosphates, carbonates, and citrates. These alkaline substances are inactivated by boiling.

Cleavage of α - and β -methyl glucosid by *Aspergillus niger*, A. W. DOX and R. E. NEIDIG (*Biochem. Ztschr.*, 46 (1912), No. 6, pp. 397-402, fig. 1).—In the experiments 8 species (*A. niger*, *A. clavatus*, *A. fumigatus*, *Penicillium camemberti*, *P. expansum*, *P. chrysogenum*, *P. roqueforti*, and *P. digitatum*) were cultivated in a solution consisting of 0.5 gm. magnesium sulphate, 1 gm. sodium phosphate, 0.5 gm. potassium chlorid, 2 gm. ammonium nitrate, and 0.01 gm. ferrous sulphate in 1,000 cc. of water for the purpose of studying the effect of α - and β -methyl glucosids upon the intensity of the growth. There was approximately 2 per cent of the methyl glucosids present. The fungi grew much better in the β -methyl glucosid than in the α form.

A. niger acts only slightly on the β form, and practically not at all on the α -methyl glucosid. Yeast, on the other hand, acts only on the α form.

Determination of alkalis in silicates by decomposition with calcium chlorid, E. MÄKINEN (*Bul. Com. Geol. Finlande*, 1911, No. 26, pp. 8).—The method suggested is as follows: Five gm. of the finely powdered silicate, and the greatest part of 5 gm. of dry calcium chlorid is mixed and placed in a platinum crucible (of such a size that the mixture will not fill more than two-thirds of the vessel); the remainder of the calcium chlorid is spread over the mixture, and the crucible heated with a slight flame for from 5 to 10 minutes in order to dry the moist calcium chlorid. The flame is then gently raised until all of the calcium chlorid is melted, after which it can be raised to any height without any danger of the mixture spurting. The heating is continued until the melt begins to solidify, which requires about one-half hour. After cooling, the mass is treated according to the J. Lawrence Smith method, that is, it is

digested, preferably in a platinum dish, with hot water until it is resolved into a loose condition.

The residue, insoluble in water, is removed by filtration, and the calcium in the filtrate is precipitated with ammonium hydroxid and ammonium carbonate. As the precipitate occupies a comparatively large space, it is redissolved in dilute hot hydrochloric acid and reprecipitated with ammonium hydroxid and ammonium carbonate. The combined filtrates are evaporated to dryness, and after driving off the ammonium salts with the aid of heat, the residue is dissolved in the smallest possible amount of water. The last traces of calcium are precipitated from this solution in a platinum dish with ammonium hydroxid and ammonium carbonate, allowed to stand for several hours, and filtered into a small tared platinum dish in which the alkalis, after removing the ammonium salts, are weighed. The potassium is then determined as potassium platinic chlorid, and from the difference the sodium is calculated.

Tests were made for the purpose of determining the amount of potassium and sodium in calcium chlorid, and some other tests to determine whether the alkali chlorid contained calcium, magnesium, or sulphuric acid.

The J. Lawrence Smith method gave lower results, but the author's method was easy to conduct.

New methods for the examination and judgment of soils, J. KÖNIG (*Abs. in Ztschr. Angew. Chem.*, 25 (1912), No. 39, pp. 2001, 2002).—The methods mentioned are chiefly those already noted in the literature, namely, the determination of the catalytic power of soils and the nutrients made soluble by treatment with steam under pressure (E. S. R., 17, p. 1138); determination of the inorganic nutrient substances which can be liberated as a result of oxidizing humus (E. S. R., 19, p. 718); influence of a strong constant electric current upon the soil; determination of the osmotic pressure (E. S. R., 21, p. 409; 26, p. 217), and the electrical conductivity of the soil (E. S. R., 24, pp. 521, 522; estimation of the amount of colloids in soils (E. S. R., 26, p. 519); the use of dialysis in the examination of soils; and determination of the oxidizing capacity of the soil.

At present the author is engaged in separating the components of the soil with solutions of various specific gravities, i. e., mixtures of bromoform and benzol, specific gravity 2.65, 2.5, 2.4, 2.3, etc. These results will be reported upon later. See also a previous note by May and Gile (E. S. R., 21, p. 220).

The determination of lime in cow feces, R. A. DUTCHER (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 1, pp. 37, 38).—It is maintained that methods of ash analysis are very lax with reference to the acid treatment of the ash. The author was unable to find anything in the literature in regard to the analysis of the ash in cow feces. He suggests that "the ash be boiled at least 3 hours with concentrated nitric or hydrochloric acid, and that the acid-insoluble residue be evaporated to dryness with dilute sodium hydroxid to break up all silicates. This alkaline residue should then be taken up with dilute acid and added to the original solution for analysis."

Water analysis for sanitary and technical purposes, H. S. STOCKS (*London, 1912, pp. VIII+136, figs. 8*).—This book deals with the physical, organoleptic, and chemical (qualitative and quantitative) analysis of water. Among the topics discussed are deleterious metals; gases contained in solution; standards of purity recommended by the Rivers Pollution Commissioners; tabular view of the standards for effluents adopted by various authorities; average composition of unpolluted water; tension of aqueous vapor; loss of nitrogen by evaporation of NH_4HSO_3 and $\text{NH}_4\text{H}_2\text{PO}_4$; Warington's method of estimating nitrates; and preparation of reagents required for water analysis. Several conversion tables are included.

Methods of analysis used in the laboratories of the Armour Institute of Technology.—Mineral analysis of water (*Chem. Engin.*, 17 (1913), No. 3, pp. 117, 118).—The methods described are for total solids, silica, iron and aluminum, calcium, magnesium, sulphuric acid, alkalis, carbonates, chlorids, and free carbon dioxide. The methods of calculating the results are also given.

Food control by police officials, W. BREMER (*Die Nahrungsmittelkontrolle durch den Polizeibeamten*. Berlin, 1910, pp. IV+73).—This is a description of methods of sampling for food inspection purposes. The substances which are prohibited are described in detail.

A rapid method for determining fat in cacao with the Zeiss refractometer, O. RICHTER (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 24 (1912), No. 5, pp. 312–319).—The methods for determining fat in milk are not applicable to the determination of this constituent in cacao, but the use of the refractometer for this purpose suggested itself. The method which apparently gave good results embodied extraction of the material with ether-alcohol-trisodium phosphate solution, determining the refraction of the fat, and calculating the amount of fat present from the results by tables which are included.

Changes in the methods for determining succinic and malic acids in wine, C. VON DER HEIDE and E. SCHWENK (*Ztschr. Analyt. Chem.*, 51 (1912), No. 10–11, pp. 628–638).—A modification of the methods originally suggested by von der Heide and Steiner (*E. S. R.*, 21, pp. 304, 305).

Studies in regard to the dry substance (total solids) of milk, A. SPLITTGERBER (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 24 (1912), No. 8, pp. 439–507).—A study was made for the purpose of determining to what degree the milk constituents suffer decomposition when dried for a long time.

The changes produced in the dry substance were, in most instances, primarily due to the presence of lactic acid. This acid, when heated at the usual drying temperatures, will volatilize almost completely, but when present with either casein, albumin, protein, lactose, or in milk itself, it becomes bound or fixed to these constituents. The remainder of the acid present is decomposed, this being entirely dependent upon the amount present and the time of drying.

A loss in weight for normal milk, due to the presence of lactic acid, is usually not noted during the first hour of drying, but after 2 hours it is appreciable. Casein, a mixture of milk sugar and phosphates, and casein with milk and phosphates after drying over 1 hour showed a marked loss in weight. According to these findings the figures obtained by the usual drying methods do not represent the sum of the total solids of milk, but those given after 1 hour of drying are probably correct.

This behavior of lactic acid probably explains the fact that in the determination of the solids in sour milk the figures obtained do not correspond with those given by the calculation methods.

The conservation of samples of milk destined for analysis, X. ROCQUES (*Ann. Chim. Analyt.*, 17 (1912), No. 11, pp. 413–418).—One gm. of bichromate of potash per liter is generally used in France for preserving milk intended for analysis, but if the bichromate is added to milk in which decomposition has already set in disintegration proceeds more rapidly. Thinking that it was the lactic acid which destroyed the preserving power of the bichromate, the author made some tests with solutions of these substances. He found that lactic acid reduced bichromate. The bichromate had no effect upon lactose, but lactose seemed to accelerate the decomposition of the bichromate.

The conclusion is reached that bichromate of potash is an excellent preservative for samples of fresh milk, but that when the sample is in a state of decomposition it is necessary to examine it as quickly as possible.

The preservation of milk samples destined for analysis, G. DENIGÉS (*Ann. Falsif.*, 5 (1912), No. 50, pp. 559-561).—Despite the conclusion of Rocques, noted above, that bichromate of potash is a satisfactory preservative for milk samples, it is maintained that the method does not work well in everyday practice. The recommendation of Dubois for the substitution of a solution of 50 gm. of phenol in 10 cc. of 95 per cent alcohol, using 1 cc. of this preservative to 100 cc. of milk, was found very satisfactory by the author. Some of Dubois's analyses made in 1900, also an analysis made of one of the samples collected in 1900 and reanalyzed in 1910, are shown. Practically no change in the composition of the sample took place.

The detection of peanut oil in olive oil, L. ADLER (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 23 (1912), No. 12, pp. 676-679, fig. 1).—A description is given of a modification of the Franz method in which it is possible to detect an addition of at least 5 per cent of peanut oil to olive oil.

One cc. of the oil and 5 cc. of an 8 per cent alcoholic potassium hydrate solution (80 gm. of potassium hydrate treated with alcohol and enough 90 per cent alcohol to make 1 liter) are placed in a 100 cc. Erlenmeyer flask provided with an 80 cm. cooling tube. The mixture is heated for 4 minutes in a boiling water bath, shaken frequently, and cooled to 25° C.; 1.5 cc. of dilute acetic acid (1 volume acetic acid and 2 volumes water) and 50 cc. of 70 per cent alcohol by volume are added; the mixture is then shaken and allowed to stand.

If the solution does not clear up, it should be heated until clarification has taken place, then cooled to exactly 16°, shaken repeatedly at this temperature for a period of 5 minutes, and if no definite turbidity is noted, cooled to 15.5°. If no turbidity is produced after another 5 minutes, the oil contains less than 5 per cent of peanut oil.

The detection of peanut oil in olive oil according to the Franz-Adler method, H. LÜERS (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 24 (1912), No. 11, pp. 683, 684).—Two samples of olive oil which were examined according to the Franz-Adler method showed a marked precipitate at 16° C., which pointed, according to the originators of the test, to the presence of about 5 per cent of peanut oil. On the other hand, when the oils were examined by the lead salt method of Torelli and Ruggeri (*E. S. R.*, 10, p. 413), peanut oil was apparently absent. A chemical study then made of the oils showed that the precipitate produced in the Franz-Adler test in these instances consisted of a potassium salt of myristic acid, and consequently it was assumed that these oils were characterized by a high myristic acid content. The amount of acid added in the Franz-Adler test is considered insufficient to cause the liberation of the entire acid in every instance, and consequently a precipitate of the acid salt is produced at from 15 to 16°.

On the basis of the above findings the method was modified.

Technical accounting and chemical control in sugar manufacture, D. L. DAVOLL, Jr. (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 3, pp. 231-234; 4, pp. 313-319, figs. 6).—A detailed description of the topic, which includes the chemical methods utilized in sugar control.

The sugar content of maize stalks, G. N. BLACKSHAW (*So. African Jour. Sci.*, 9 (1912), No. 3, pp. 42-48).—Continuing previous work (*E. S. R.*, 27, p. 314), the author reports results of more extensive experiments with Hickory King, Boone County, Salisbury White, Golden Eagle, and Sweet corn, sown November 9. From a portion of each plot, the cobs were removed in a milky condition on April 2, and the juice of stalks selected from the cobbed and uncobbed portions analyzed periodically until the crop reached maturity.

All of the cobbed plants, with the exception of Sweet corn, examined between April 10 and May 23, i. e., from 8 to 51 days after removing the cobs, showed

an average sucrose content of 12 per cent. In the juice from the stalks of plants on which the cobs were allowed to remain, the average amount of sucrose was 8.2 per cent. Plants cobbled at the same period, that is, between April 2 and 9 showed an average of 11.5 per cent of sucrose. It is estimated that the stalks would yield about 585 lbs. of sucrose per acre, and 80 lbs. of glucose.

Objectionable nitrogenous compounds in sugar-cane juice, F. ZERBAN (*Orig. Commun. 8. Internat. Cong. Appl. Chem. [Washington and New York], 8 (1912), Sect. Va, pp. 103-111*).—After reviewing the literature pertaining to the injurious nitrogen which is contained in very small amounts in sugar-cane juice, the author states that none of the different substances reported, viz, leucin, asparagin, glutamin, and glycocoll has been definitely identified. As a result of the investigation it was found that the mercuric precipitate from sugar-cane juice contains principally asparagin, and small amounts of glutamin and tyrosin. The fact that asparagin was present is corroborated by L. M. Dennis of the laboratory of Cornell University.

The investigations were carried out in two different places. "The first of these, the Agricultural Experiment Station in Tucuman, Argentina, lies within the Temperate Zone, while the second, the experiment station of the Porto Rico Sugar Producers' Association, is in the Tropics. The methods used were practically the same in both places."

The practical results to be obtained by determining the injurious nitrogen in sugar beets, G. FRIEDL (*Kisérlet. Közlem., 15 (1912), No. 5, pp. 801-808*).—The figures for available white sugar on the basis of the injurious nitrogen content of the beet were lower than the values shown by Stammers' calculations. The amount of molasses obtained agreed well with the injurious nitrogen determination. Very valuable data can be obtained by determining the injurious nitrogen colorimetrically (E. S. R., 23, p. 514).

Inversion of saccharose and its relation to the qualitative changes of various feed beets during storage, W. JEKELIUS (*Kühn Arch., 2 (1912), pt. 1, pp. 149-192, figs. 3*).—The relation noted by Stephani (E. S. R., 29, p. 111) between the diminution of polarization and the formation of invert sugar with various kinds of beets during storage was confirmed by this investigation. Varieties with a high sugar and dry substance content showed a lower inverting capacity than beets having a low total solid content, while the tendency to invert sugar formation stood in a direct relation to the yield of beets. No relationship between inverting capacity and the other constituents of beets, i. e., nitrogen, protein, ash, and the ash constituents, could be established.

The inversion noted seems to be a purely physiological process, but it is also influenced by external conditions. For instance, injuring a beet, or boring brings about a marked inversion of the saccharose. Temperature and the methods of storage also influence the degree of inversion. Total sugar and dry substance seem to run fairly parallel also in stored beets. Accordingly, the estimation of the dry substance in the spring in beets high in invert sugar will give us a better measure than will the polarization test. With varieties which show a low degree of inversion, polarization in the spring will give the identical figures obtained with the gravimetric method for total sugars.

The determination of total sugars stands in direct relation to the formation of invert sugar; there are, however, varieties and individual beets which can produce up to springtime considerable invert sugar without showing marked loss of total sugar. Inversion and polarization of sugar can, according to this, be two functions which are independent of one another.

Manufacture of a sugar-beet flour (beet meal), and its use in the alimentation of man and beast, A. AULARD (*Orig. Commun. 8. Internat. Cong. Appl. Chem. [Washington and New York], 25 (1912), Sects. I-Ve, pp. 479-483*).—This

describes the method of preparing beet meal by a drying process. The product has a composition as follows: Protein, 6.6; saccharose, 65.5; other carbohydrates, 12.75; cellulose (saccharifiable), 5.2; ether extract, 0.75; water, 5.4; residue, inert material, salts, etc., 3.8 per cent. The cost of drying the material under conditions prevailing in Belgium and France is also discussed.

Composition of apples and pure ciders of the lower Seine regions, C. BRIOUX (*Ann. Falsif.*, 6 (1913), No. 51, pp. 32-39).—This deals with the composition of the apples harvested in 1911 and the cider made therefrom. Ciders made from a single variety of apples and several varieties of apples are considered.

Cider vinegar and its making, P. J. O'GARA (*Off. Path. and Ent. Rogue River Valley Oreg. Circ.* 1, 1912, pp. 4).—This is a short popular description of making vinegar from pure apple juice, issued for the purpose of pointing out a method for utilizing cull apples which would otherwise go to waste.

The composition of pure wine from American native grapes, W. B. ALWOOD (*Abs. in Orig. Commun.* 8. *Internat. Cong. Appl. Chem.* [Washington and New York], 26 (1912), Sects. VIa-XIb, pp. 35, 36).—This paper deals with experiments on the manufacture of straight wines from 8 native grapes, the purpose being to ascertain the facts in regard to the composition of pure grape must after it has been fermented to dryness.

The alcohol industry of the Philippine Islands, H. D. GIBBS (*Philippine Jour. Sci.*, Sect. A, 6 (1911), Nos. 2, pp. 99-145, pls. 8, figs. 3; 3, pp. 147-206, pls. 12, figs. 5).—This deals with the study of the nipa palm, coconut palm, buri palm, and sugar palm, with special reference to the saps and their uses. Among other factors it discusses the tapping of the palm, the yield, composition, and utilization of the sap, the occurrence of mannitol in palm saps, the sap of the coconut palm as a source of sugar and vinegar, the economic factors concerned in the production of sugar, etc.

The cooperative manufacture of casein, P. DORNIC (*Indus. Beurre*, 7 (1912), Nos. 28, pp. 325-327; 29, pp. 337-339; *abs. in Internat. Inst. Agr.* [Rome], *Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 9, p. 2079).—A small society at Sainte-Soulle, manufacturing casein from skim milk from June 1, 1911, to May 31, 1912, utilized 366,600 gal. of skim milk, which yielded 114,185 lbs. of casein, and a profit greater than had previously been received from feeding the skim milk to pigs.

Synthetic tannin, B. F. CHASE (*Daily Cons. and Trade Rpts.* [U. S.], 16 (1913), No. 106, p. 673).—The preparation which is termed "Neradol" is made by sulphonating cresylic acid and combining it with formaldehyde. The preparation is supposed to be somewhat similar to ordinary tanning extract, and forms a light brown solution in water. It is reported that a number of tests have been made with sheep, calf, and other skins with apparently satisfactory results.

The effect of "lime-sulphur" spray manufacture on the eyesight, J. R. WITHEROW (*Jour. Indus. and Engin. Chem.*, 4 (1912), No. 10, pp. 735-737).—This is a description of some cases where the eyes of workmen engaged in the preparation of lime-sulphur wash became inflamed, resulting in blurred vision. This was especially the case on cold days, when the opportunities for proper ventilation of the factories were poor.

METEOROLOGY—WATER.

Syllabus of questions on the relation between meteorological information and agricultural practice, W. N. SHAW (*Rpt. Brit. Assoc. Adv. Sci.*, 1912, pp. 738, 739).—A series of questions designed to bring out the relation between climatic conditions and plant growth is given.

"Surface" climate, W. L. BALLS (*Rpt. Brit. Assoc. Adv. Sci.*, 1912, pp. 739, 740).—This article calls attention to the wide variations in temperature, humidity, etc., which may occur among crops within even a few inches of altitude. It is stated that in observations on the cotton crop in Egypt it was found "that a puff of wind arising during an otherwise calm, clear night will raise the temperature of the crop by more than 5° C. Since the growth of the plant is controlled chiefly by night temperature, such a rise is not without importance. The explanation lies in the removal of air which has been chilled by radiation from the plant, and its replacement by air at 'screen temperature.' Transpiration of water from the plant is negligible at night."

Meteorological conditions in a field crop, with a description of two simple recorders, W. L. BALLS (*Quart. Jour. Roy. Met. Soc. [London]*, 39 (1913), No. 166, pp. 109-113, figs. 3).—This article reports the results of observations on temperature, humidity, and wind movement in a field of cotton in Egypt as noted in the abstract above. It also describes simple forms of an anemograph and a differential thermograph used in these observations.

Meteorological yearbook for 1913 (*Annuaire Météorologique pour 1913. Brussels, 1912, pp. VI+323, pls. 39, figs. 7*).—This volume contains a climatological review for Belgium for 1912, a summary of meteorological observations at the Uccle observatory, and a detailed study of hail and other storms in Belgium, besides special articles on the Besson nephoscope, comparative tests of different forms of shade thermometers, ascensions of sounding balloons, temperature of the North Sea, and infiltration of meteoric waters in the soil as measured by a lysimeter.

Temperature records, J. B. THOMPSON (*Guam Sta. Rpt. 1912, pp. 28, 29, figs. 2*).—Records of maximum and minimum temperatures at the Guam Station throughout the year ended June 30, 1912, are shown in charts.

Rain and its measurement, L. DUMAS (*Ann. Gembloux, 23 (1913), No. 6, pp. 261-299*).—The author deals in a broad general way with the phenomenon of rainfall and with rain and snow in their relations to climate, locality, and agriculture. He discusses evaporation from air and soils, humidity, temperature, and intensity of rainfall in their relations to each other, and also the accuracy of rain gages. He takes up particularly the relation of rainfall to soil and vegetation, considering as the normal rainfall for a region that amount which satisfies the average cultural conditions.

Conservation of rainfall, W. J. SPILLMAN (*U. S. Senate, 63. Cong., 1. Sess., Doc. 228, 1913, pp. 5*).—Attention is called in this document to the beneficial results obtained by the use of a system of embankments for conserving rainfall and preventing soil erosion on a light sandy soil which includes forests, pastures, and cultivated fields.

Surface water supply of the South Atlantic coast and eastern Gulf of Mexico drainage basins, 1911, M. R. HALL and C. H. PIERCE (*U. S. Geol. Survey, Water-Supply Paper 302, 1913, pp. 90, pls. 4*).—This paper reports the results of measurements of flow made during 1911, in the James, Roanoke, York, Savannah, and Altamaha river basins on the South Atlantic coast, and in the Apalachicola, Choctawhatchee, Escambia, and Mobile river basins of the east coast of the Gulf of Mexico. Tables are also included giving gage heights and daily and monthly discharges at each station. A summary of the discharge per square mile indicates an almost entire lack of uniformity or agreement between any two stations.

Geology and ground waters of Florida, G. C. MATSON and S. SANFORD (*U. S. Geol. Survey, Water-Supply Paper 319, 1913, pp. 445, pls. 16, figs. 7*).—This paper gives a detailed report on the geography, stratigraphy, and geologic his-

tory of Florida, with special reference to its underground water. The water supply of each county as well as of the State as a whole is discussed with reference to its source, quality, and development, and tables giving data for typical wells of the State are added to many of the county descriptions. The illustrations include a general topographic and geologic map of Florida, a map of its Pleistocene terraces, a diagram showing the importance of choosing proper locations for wells, and half-tones showing features of geologic interest.

Surface water supply of the Ohio River basin, 1911, A. H. HORTON, M. R. HALL, and H. J. JACKSON (*U. S. Geol. Survey, Water-Supply Paper 303, 1913, pp. 112, pls. 4*).—This paper reports results of measurements of flow made on the Ohio River and its tributaries during 1911. Tables are also included giving gage heights and daily and monthly discharges at each station. A comparison of relative rates of run-off from different areas in this basin shows an almost entire lack of uniformity or agreement between any two streams.

The Ohio Valley flood of March-April, 1913, A. H. HORTON and H. J. JACKSON (*U. S. Geol. Survey, Water-Supply Paper 334, 1913, pp. 96, pls. 22*).—This report contains available recent flood data from the Ohio River Valley, together with facts concerning earlier floods, which are presented primarily for comparison with those concerning the flood of 1913. It is attempted to show what can and should be done in collecting the data necessary for a complete report on the floods in the Ohio Valley and emphasizes the necessity of immediately starting, on a comprehensive scale, the collection of stream-flow data not only from the Ohio itself but from its larger tributaries to the end that a definite decision may be reached as to the best and most economical means of preventing damage by floods.

Geology and water resources of Sulphur Spring Valley, Ariz. (*U. S. Geol. Survey, Water-Supply Paper 320, 1913, pp. 1-187, 214-231, pls. 14, figs. 32*).—This work represents a cooperative investigation, between the United States Geological Survey and the Arizona Experiment Station, of the ground waters and possibilities of irrigation in the valley.

The physiography and drainage; geology; rainfall; occurrence; level, and quality of ground water; vegetation in relation to water and other geographic controls; and the artesian conditions of the valley are discussed in some detail by O. E. Meinzer (pp. 1-187), together with an investigation of the concentration, distribution, and general effect of the alkalis in the soil and water. Sodium carbonate is said to be the most harmful alkaline constituent in the soil, and where the depth to water is less than 15 ft. the soil usually contains injurious amounts of alkali, while where the depth is more than 15 ft. the soil is usually free from injurious amounts.

In addition there is a discussion by R. H. Forbes (pp. 214-224) of the agricultural resources of the valley, in which it is stated that dry farming and flood water farming are uncertain methods of culture there, while dry farming supplemented with a pumped water supply is a more certain method. See also a previous note (*E. S. R.*, 29, p. 725).

Ground water in Boxelder and Tooele counties, Utah, E. CARPENTER (*U. S. Geol. Survey, Water-Supply Paper 333, 1913, pp. 90, pls. 2, figs. 9*).—The chief purpose of this paper is to report an investigation made to determine the feasibility of irrigating by use of underground water in this region, which includes Boxelder and the eastern part of Tooele counties, Utah, and some small tracts in southern Idaho. The physiography, geology, climate, vegetation, soil, and industrial development of the region are discussed in some detail and the occurrence and quality of ground water supplies are taken up by areas, mainly from the standpoint of their availability and use for irrigation purposes. In

addition information is given regarding the location of watering places on routes of travel for the benefit of strangers traveling through the region.

The pollution of underground waters with sewage through fissures in rocks, H. ALBERT (*Science, n. ser.*, 38 (1913), No. 972, pp. 238, 239).—A case of supposed pollution of underground waters through rock fissures is noted. A water supply taken from three deep wells became polluted from the deepest well which was sunk at the bottom of a shaft used previously for water supplies and extending through 31 ft. of alluvial soil and clay, 6 ft. of limestone, 27 ft. of blue shale, 6 ft. of limestone, and 42 ft. of sandstone. From the nature of the existing strata and from bacteriological and clinical examinations of the water it is concluded that polluted river and ground water passed readily through the top layer of soil and gravel to and through the fissures in the upper layer of limestone to and along the relatively impermeable layer of shale in the direction of least resistance toward the shaft.

The sewage sludge problem and its solution, J. GROSSMANN (*Surveyor*, 43 (1913), No. 1117, pp. 926-928).—A paper on this subject is given in abstract with discussion.

The Grossmann process for recovery of grease and preparation of a sludge fertilizer in use at Oldham, England, is described. The sludge fertilizer obtained is a dry, friable, inodorous material containing about 2 per cent of ammonia, from 3 to 5 per cent of calcium phosphate, and $1\frac{1}{2}$ per cent of potash salts, and is in demand by farmers. It is said to furnish a good basis for mixed fertilizers.

SOILS—FERTILIZERS.

Soils of the United States, C. F. MARBUT, H. H. BENNETT, and J. E. and M. H. LAPHAM (*U. S. Dept. Agr., Bur. Soils Bul. 96, pp. 791, pls. 15*).—This is a combination of features of Bulletins 55 and 78 of the Bureau of Soils (E. S. R., 20, p. 915; 25, p. 426), revised to January 1, 1912. It describes the soils of this country as far as they are known at present, and includes also a discussion of methods of soil classification.

A study of the soils of Macon County, Alabama, and their adaptability to certain crops, G. W. CARYER (*Alabama Tuskegee Sta. Bul. 25, pp. 5-13*).—The soil types of the county, as defined by the Bureau of Soils, are described and their crop adaptations and methods of management are discussed. With the exception of the Norfolk coarse sand and Norfolk gravelly loam, which are so porous as to be nearly always in a drought-stricken condition, the soils are generally well adapted to the growing of field, garden, and fruit crops, and nuts. Among the fruits which may be successfully grown are apples, pears, plums, grapes, figs, strawberries, blackberries, mulberries, and pomegranates. The clay soils are said to need drainage especially, and deep cultivation and the addition of vegetable matter are suggested for all the types.

The gullied lands of west Tennessee, A. H. PURDUE (*Resources Tenn.*, 3 (1913), No. 3, pp. 119-136, figs. 8).—Attention is called to the enormous annual waste from soil wash in western Tennessee. The tendency of the soils of that locality to wash is attributed to the fact that they are loose and sandy and contain more or less clay. The conditions favorable for rapid wash of sand clay soils are stated to be steep slopes, rapid rainfall, and absence of vegetation.

Deep, close plowing, parallel to the contours and turning of the soil down hill, are urged as measures for preventing wash. It is pointed out that the existence of gullies in fields causes the ground water level to sink beyond the reach of plants and also tends to leach out and drain away soluble soil constituents and fertilizers. To prevent this and to check the spread of wash it is

suggested that the mouths and heads of gullies be filled with logs, brush, briars, and grass.

It is stated that all of the waste lands of western Tennessee can be reclaimed for one of three purposes, namely, agriculture, pasture, or timber.

The sulphur content of some typical Kentucky soils, O. M. SHEDD (*Kentucky Sta. Bul. 174*, pp. 269-306).—Examinations of representative samples of soil from the various geological areas in the State indicate that constant cultivation without manuring has resulted, in some cases, in a very large loss of sulphur as compared with the amounts in corresponding virgin soil. This was true of both surface soils and subsoils. As a rule, the better agricultural areas showed a higher content of both sulphur and phosphorus. Surface soils generally contained more sulphur than the corresponding subsoils.

The general conclusion is that any system of soil maintenance which does not include the addition of sulphur in some form will probably prove a failure.

Analysis of coconut soils, J. DE VERTEUIL (*Dept. Agr. Trinidad and Tobago Bul., 11 (1912), No. 71*, pp. 184-186).—Results of analyses of 11 samples of soils on which coconuts were being grown are reported and briefly discussed. The soils are fairly heavy clays, the proportion of clay increasing with the depth. An attempt is made to correlate the health and vigor of the coconut palms with the available plant food in the soil, but without conclusive results.

Some Lybian soils, A. MAUGINI (*Agr. Colon. [Italy], 7 (1913), No. 9*, pp. 321-332).—Mechanical, physico-chemical, partial chemical, and mineralogical analyses were made of six samples of soil, three of which were taken from interior oases and three from dry stream beds in the Lybian Desert.

The substrata of the oases, although they are widely separated, were identical, consisting of variegated clay marl alternating with streaks of silicious limestone. The substrata of the dry stream beds were composed of alluvial earth derived from the disintegration of the limestones and marls which formed the original stream bed.

The vegetation of the oases consisted of date palms, cereals, legumes, olives, figs, pomegranates, cotton, tobacco, and barley. That of the dry stream beds consisted of several tropical plants, common Bermuda grass, and a kind of legume.

The soils examined varied in color from reddish gray to dark brown and were found to be either slightly alkaline or neutral. They belong in general to the category of loose soils, being often deficient in grit and composed mainly of small particles, although the content of impalpably fine particles is small. To this is attributed the small water-holding capacity and permeability of these soils.

The soils contained a relative abundance of potash, very little of which, however, was in a form to be available for plants. Organic matter and consequently nitrogen and also phosphoric acid were insufficient in both quantity and availability. Mineralogically all the soils with the exception of one stream bed sample had essentially the same composition, quartz incrustated with iron oxid predominating in the fine earth. The greatest difference in the soils from the two sources was in the quantity of carbonates, which was small in the oasis soils and large in the stream bed soils.

The fine earth in the oasis soils was largely sandy material while in the dry stream bed soils it was largely clay. The structure of the dry stream bed soils is deemed the better of the two. A comparison of these interior oasis soils with those of coastal oases leads to the conclusion that they are from a common origin.

The alkaline soils in Egypt and their treatment, V. M. MOSSÉBI (*Bul. Inst. Égyptien*, 5. ser., 5 (1911), No. 1, pp. 53-79).—An examination of unproductive soils in different parts of Egypt showed the widespread existence of injurious alkali, consisting principally of carbonate, bicarbonate, chlorid, and sulphate of sodium. Of these the carbonate is considered the most injurious to both plant growth and the physical condition of the soil, it being found without exception that unproductive, compact, impervious soils difficult to drain contained sodium carbonate in large or small amounts, and also bicarbonate in amounts usually from two to three times those of the carbonate. A strong soil containing 0.08 per cent of sodium carbonate is said to be rendered absolutely useless. The bicarbonate of sodium, however, is considered to be less harmful than the chlorid.

It was demonstrated that gypsum in proper amounts, in addition to overcoming the toxic effect of sodium carbonate, corrected its effect on the porosity and permeability of the soil. It is concluded in general that the gypsum should be applied in double the amount theoretically required and in two or three treatments well distributed and well mixed with the top layer of soil. A copious irrigation after a treatment is said to aid the chemical reaction between the gypsum and the sodium carbonate, and good drainage is considered indispensable.

Tests of the solubility of the local gypsums relative to fineness are recorded, the solvents used being water, 1 per cent hydrochloric acid, and one-hundredth normal hydrochloric acid. It is concluded that a degree of fineness allowing it to pass a sieve having 34 meshes per linear centimeter is sufficient.

The movements of soil water in an Egyptian cotton field, W. L. BALLS (*Jour. Agr. Sci. [England]*, 5 (1913), No. 4, pp. 469-482, figs. 7; *abs. in Internat. Inst. Agr. [Rome]*, Mo. *Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 12, pp. 1845-1847).—This paper describes and discusses a series of soil water determinations made in a field of cotton at Giza, in Egypt. These were made every three or four days alternately and at 20 cm. intervals down to 160 cm. The soil is alluvial the first 30 cm., the next 60 cm. stiff clay, the next 110 cm. loam to sandy loam, and below 200 cm. stiff clay. The rate of evaporation from this field of cotton plants averaged about 20 tons per acre of water a day from May to October.

The chief conclusions drawn from these determinations are as follows: (1) The depth of root may be roughly traced by its drying effect on the soil, which combined with a change in surface climate causes a reversal of the humidity gradient so that deep soil is drier than surface soil in September. (2) Application of irrigation water to the surface is evidence to an indefinite depth and absence of such evidence is due to imperfection in the method of observation. (3) Determination of soil water content in an Egyptian cotton field by random sampling is almost worthless unless due regard is paid to the seasonal variation. (4) The water of the water table when within 2 meters of the surface may be utilized by the crop. (5) A rise of the water table is analogous to surface irrigation and there is some indication of a direct hydraulic thrust in both cases.

The water balance and losses of plant food in fallow loam and sandy soils, 1905-1912, C. VON SEELHORST ET AL. (In *Festschrift zum siebenzigsten Geburtstage von Jacob Esser*. Berlin, 1913, pp. 1-27; *Jour. Landw.*, 61 (1913), No. 3, pp. 189-215).—The investigations summarized in this article were made in vegetation tanks of 1½ cubic meters content.

The results show that evaporation was larger from the loam than from the sandy soil, each being repeatedly cultivated each summer during the period

covered by the experiments. The losses of plant food in the drainage were as follows:

Losses of plant food in drainage water from loam and sandy soils in pounds per acre.

Year.	Nitrogen.		Lime.		Magnesia.		Sulphuric acid.	
	Sandy soil.	Loam.	Sandy soil.	Loam.	Sandy soil.	Loam.	Sandy soil.	Loam.
	<i>Pounds.</i>	<i>Pounds</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>
1908.....	17.4	34.5	161.3	212.7	17.1	28.5	88.7	84.4

On a new method of measuring the capillary lift of soils, C. J. LYNDE and H. A. DUPRÉ (*Jour. Amer. Soc. Agron.*, 5 (1913), No. 2, pp. 107-116, figs. 3).—The apparatus used in the method proposed, which is similar to that of Askenasy (*E. S. R.*, 7, p. 19), consists essentially of an ordinary glass funnel 4 cm. in diameter connected with a thick-walled capillary tube about 90 cm. long by means of a piece of rubber tubing. This joint is water sealed by means of "a glass tube, 2 cm. in diameter and 15 cm. long, closed at the bottom with a rubber stopper through which the capillary tube passes. The seal is filled with water and prevents air from entering about the rubber tube."

In using this apparatus a 6-gm. sample of soil is allowed to stand over night in water. It is then boiled for a short time to expel air. The funnel is fitted with a cotton cloth filter 2 cm. in diameter. A cup of a centrifuge is filled with distilled water previously boiled to expel the air and the funnel with its filter is placed in the cup, being supported by the rim of the cup. Part of the hot mixture of soil and water is poured into the funnel and the soil is settled by centrifuging. This process is repeated with more soil and water until the soil is well above the edge of the cloth filter. The capillary tube with the rubber tube attached is then filled with water previously boiled to expel air, and the funnel is inserted in the rubber tube, care being taken in doing this not to allow air to enter the funnel or tube and to avoid disturbing the soil. The lower end of the capillary tube is placed in a cup of mercury and the water seal is filled with boiled distilled water. When evaporation sets in from the surface of the soil in the funnel the mercury rises in the capillary tube and the maximum capillary lift is found by multiplying the length of the mercury column in centimeters by 13.6 and adding the length in centimeters of the water column from the top of the mercury column to the middle of the soil layer.

The advantages claimed for this method are that the moisture moves through a very short column of wet soil, reducing friction to a minimum; the time required to make a measurement is greatly reduced; and the final measurement is a fairly accurate index of the capillary lift of the soil, being approximately three times that measured by the old method. By this method the capillary lift of soil constituents was found to be greater the finer the grains, and a comparison of the calculated and observed lifts showed that the observed lifts fell between the calculated limits in every case except that of clay. The capillary lift of clay was measured under pressures equal to, greater than, and less than one atmosphere, and the results showed that the capillary lift observed by this method is limited by the pressure of the atmosphere and that, therefore, the maximum lift under a pressure of one atmosphere can not exceed 34 ft.

On osmosis in soils: The efficiency of the soil constituents as semipermeable membranes, C. J. LYNDE and H. A. DUPRÉ (*Jour. Amer. Soc. Agron.*, 5 (1913), No. 2, pp. 102-106, figs. 2).—In continuation of previous investigations (E. S. R., 29, p. 124) experiments made with medium sand, fine sand, very fine sand, silt, clay, and fine clay for the purpose of comparing the efficiencies of these soil constituents as semipermeable membranes showed that for the solution used (clay subsoil solution) the sands did not act as semipermeable membrane, but that the silt, clay, and fine clay did so act. The conclusion is drawn that the finer the soil grains in a soil constituent the greater is the efficiency of the soil constituent as a semipermeable membrane.

The method and apparatus used are described.

The action of hydroxyl ions on clay and clay soils in connection with marling, P. ROHLAND (*Landw. Jahrb.*, 44 (1913), No. 3, pp. 437-440).—The hydroxyl ions of calcium and other hydroxids act upon the clay of soil, forming and flocculating colloid substances. This effect is greatest the first time clays and clay soils are subjected to the action of the ions and diminishes when the action is repeated until the clay particles lose the property of forming colloids. This is said to explain the diminishing effect of repeated liming.

The properties of so-called soil zeolites, E. BLANCK (*Fühling's Landw. Ztg.*, 62 (1913), No. 16, pp. 560-581).—The principal results of investigations bearing on this subject are summarized, indicating the lack of exact information as to the so-called zeolites of the soil. These are shown to be in no sense equivalent to the mineral zeolite but may be more properly designated simply as adsorptive gel mixtures of indefinite and variable mineralogical and chemical composition.

Factors in the maintenance of permanent fertility of the soil, E. O. FIPPIN (*Jour. Amer. Soc. Agron.*, 5 (1913), No. 1, pp. 46-49, fig. 1).—A diagram in the form of a monument is presented which "is made up of the general practices available for improving the soil put together according to their functional relations and in the order of their range of influence." The foundation of this diagram is the proper regulation of soil moisture, involving drainage and irrigation. Lime in the form of free lime carbonate constitutes the second course. Organic matter, chiefly in the form of humus, forms the third course. Tillage in its various forms constitutes the fourth course, and plant food in the form of fertilizers is placed last with the elements, phosphorus, sulphur, nitrogen, and potassium, arranged in the order in which they are most likely to be needed.

The agricultural utilization of acid lands by means of acid-tolerant crops, F. V. COVILLE (*U. S. Dept. Agr. Bul.* 6, pp. 13).—The essential features of this paper have already been noted from another source (E. S. R., p. 814). The points emphasized as of special importance to agricultural investigators are "(1) that soil acidity is not always an objectionable condition which invariably requires an application of lime, (2) that under certain economic conditions a complete system of acid-land agriculture is practicable and desirable, and (3) that the extent to which our cheap eastern acid lands can be utilized with small applications of lime, or under some conditions without its use, is a legitimate and important subject for detailed investigation, from which may reasonably be expected results of far-reaching economic importance."

Formation of nitrates in soil after freezing and thawing, T. L. LYON and J. A. BIZZELL (*Jour. Amer. Soc. Agron.*, 5 (1913), No. 1, pp. 45, 46).—Four pots of soil, two containing Volusia silt loam and two Dunkirk clay loam soil on which had been raised a crop of wheat and one of millet were used in these experiments. One pot of each kind of soil was subjected to freezing and thawing and the other two were kept at a temperature above 50° F.

The determination of nitrates in these soils after this treatment showed that freezing had produced a condition of soil favorable for nitrate formation. This

is attributed to the effect of freezing in overcoming the depressing influence of the crops previously grown.

The accumulation of green manure nitrogen in sandy soils, C. von SEELHORST ET AL. (*Arb. Deut. Landw. Gesell.*, 1913, No. 241, pp. 147, pls. 20).—A summary of the results of 6 years' experiments in vegetation tanks, here reported in detail, has previously been noted (*E. S. R.*, 26, p. 224).

Manures and fertilizers, H. J. WHEELER (*New York*, 1913, pp. XXI+389, pl. 1, figs. 62).—This is the ninth volume in The Rural Text-book Series, edited by L. H. Bailey.

The author states that "the preparation of this volume was undertaken for the purpose of meeting a distinct lack in collegiate agricultural text-books in the United States. It was hoped to prepare a book reasonably free from extended details, such as are found in certain of the larger foreign works, and likewise to avoid the rather superficial treatment of the subjects which has necessarily characterized many of the books which have been written for the purpose of meeting the earlier requirements of the American agricultural colleges, and the present demands of agricultural high schools. The intent has been to provide in a measure for the needs of the graduate student in agriculture; also for the requirements of students in the agricultural colleges, teachers in agricultural schools, graduates of agricultural schools and colleges, agricultural institute lecturers, and the rapidly increasing number of intelligent men who are daily interesting themselves in the scientific phases of modern farming."

In a historical introduction the author gives in a few pages a summary of the major steps in the scientific development of the use of manures and fertilizers. Then follow chapters dealing with night soil; the dung of farm animals and its preservation; the organisms and fermentation of dung; the practical utilization of manures; sea weeds; guanos; fish, crab, lobster, and similar wastes; common slaughter-house nitrogenous waste products; other miscellaneous nitrogenous substances; the availability of organic nitrogen and factors affecting it; calcium and potassium nitrates; nitrate of soda; ammonium salts and calcium cyanamid; natural phosphatic fertilizers; manufactured phosphates and studies of solubility; potassic fertilizers; the theory and practice of potash fertilization; lime and its relation to soils and fertilizers; liming in its relation to plants; gypsum and waste lime from industries; magnesia as a fertilizer; sodium salts; iron and manganese; and chlorine, sulphur, silica, carbon disulphid, toluene, and other miscellaneous substances.

In the discussion of many important features of the subject the author has drawn freely upon the results of his own well-known investigations relating to plant nutrition and soil requirements at the Rhode Island Experiment Station because, as he observes, "he can speak of these results in a more authoritative way than of work done elsewhere," and because "the work has been, in some respects, of a pioneer character, and has not been duplicated."

Some of the subjects which are perhaps more fully treated than in most text-books of this kind are guano and human excrement (largely historical); seaweed (not, however, dealing with the recent exploitation of Pacific coast seaweeds as a source of potash); the bacterial changes in animal excrements; the relative availability of nitrogenous manures; the relative value (especially cumulative and indirect effects) of nitrates and ammonium salts; the new synthetic nitrogenous fertilizers—calcium cyanamid and calcium nitrate; and the function in soil improvement and plant growth of lime, magnesia, soda, manganese, and various catalytic fertilizers.

The book is well indexed.

Experiments with fertilizers, manure, lime, and floats, C. E. THORNE and E. MOHN (*Ohio Sta. Bul.* 260, pp. 405-448, figs. 5).—This is a report on experiments at the northeastern test farm of the Ohio Station at Strongsville.

"These experiments, which are still in progress, were begun in 1895 on a cold, heavy clay, lying over compact, argillaceous shales. Part of the land had been in pasture for many years before the experiments were begun, and part under tillage.

"Wherever phosphorus has been applied on this land, whether carried in acid phosphate, bone meal, or raw phosphate rock, it has produced a profitable increase of crop.

"Nitrogen and potassium, while increasing the crop, have produced a smaller effect than phosphorus, especially in the earlier years of the work. During more recent years there has been a slowly increasing effect from these elements.

"While nitrate of soda and muriate of potash have been used at a loss, the fact that the largest yields of crops have been harvested only when the fertilizer has carried nitrogen and potassium in some form indicates the necessity of supplying these elements in some cheaper carrier than chemicals.

"For eight years several brands of factory mixed fertilizers were compared with home mixtures of equivalent composition, made of tankage, acid phosphate, and muriate of potash. The outcome of this test was a greater increase of crop from the home mixtures than from the factory mixtures in every case, while the cost of the home mixtures was much less than that of the factory mixtures.

"Acid phosphate and steamed bone meal have been the most effective carriers of phosphorus. Apparently there has been very little difference in effectiveness between the pound of 'available' phosphorus in acid phosphate and the pound of total phosphorus in steamed bone meal.

"Steamed bone meal has been more effective than raw bone meal, a result which may have been due in part to the finer grinding of the steamed meal and in part to the low effect of nitrogenous fertilizers on this soil.

"Raw phosphate rock appears to have been effective in proportion to the 'available' phosphorus contained. When applied at the rate of 2,000 lbs. per acre every five years, raw phosphate rock has produced a greater increase in the cereal crops than raw limestone in twice that quantity. In the earlier experiments clover was benefited by the phosphate rock, but in more recent years the clover has failed on the phosphated land, though growing with increasing luxuriance on that receiving limestone.

"As a direct application to the land, therefore, acid phosphate and steamed bone meal have been found to be more economical sources of phosphorus than raw phosphate rock.

"Lime is as urgently needed on this land as phosphorus, it having become practically impossible to grow clover until lime has been applied, no matter how thoroughly the land was manured or fertilized."

The preservation of cattle manure (*Planters' Chron.*, 8 (1913), No. 43, pp. 550-552).—Comparative tests on a rotation of crops of deep stall manure and manure preserved in pits and heaps with and without addition of loam soil are briefly reported. These indicated that for the shallow-rooted crops the best results were obtained with the manure containing the largest amount of organic matter, the effect being due largely to the mechanical condition of the manure rather than to its relative percentage of fertilizing constituents.

The deep stall manure contained on the basis of dry matter 56.9 per cent of organic matter, the pit manure 45.01 per cent, and ordinary heap manure 38.87 per cent.

The effects of fertilizers other than that of adding plant food, L. L. VAN SLYKE (*Cornell Countryman*, 11 (1913), No. 2, pp. 51-53).—This article discusses briefly certain secondary and subsidiary effects of sodium nitrate, ammonium sulphate, superphosphate, potassium chlorid, and potassium sulphate when applied as fertilizers. These are cited as examples "to illustrate the fact that, in applying commercial fertilizers to the soils, some account must be taken of the effects other than those of supplying plant food. If this is not done, not only may the applied plant food fail to produce the desired effect but even act injuriously."

The nitrogen content of night soil from the city of Florence, N. PASSERINI (*Atti R. Accad. Econ. Agr. Georg. Firenze*, 5. ser., 10 (1913), No. 4^a, pp. 353-360; *Bol. Ist. Agr. Scandicci*, 2. ser., 7 (1913), No. 4, pp. 315-322).—Analyses of a number of samples of both solid and liquid material are reported.

Tests of the agricultural value of the nitrogen of "Poudro", M. DE MOLINARI and O. LIGOT (*Ann. Gembloux*, 23 (1913), No. 11, pp. 537-544, figs. 2).—"Poudro" is a fertilizer prepared from household garbage and contains, according to the analyses reported, from 0.39 to 0.84 per cent of nitrogen and somewhat smaller amounts of phosphoric acid and potash. In pot experiments with oats on clay soil and sand its nitrogen appeared to be quite active as compared with that of ammonium sulphate.

The production of artificial fertilizing materials from the nitrogen of the air, A. BENCKE (*Die Erzeugung künstlicher Düngemittel mit Luftstickstoff. Vienna and Leipsic*, 1913, pp. VII+204, figs. 58).—The various processes proposed for this purpose are fully described and discussed, as is the industrial value of the products.

How can the dusty condition of lime nitrogen be lessened? A. STUTZER (*Deut. Landw. Presse*, 40 (1913), No. 84, pp. 1002, 1003).—It was found that lime nitrogen mixed with from 10 to 15 per cent of ground bog iron ore kept for 7 months in good mechanical condition and without loss of fertilizing value.

On the decrease of available phosphoric acid in mixed fertilizers containing acid phosphate and calcium cyanamid, R. N. BRACKETT ET AL. (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 11, pp. 933-935).—In the experiments reported in this article it was found that there was a gradual increase of insoluble phosphoric acid in mixtures of cyanamid and acid phosphate. The experience of fertilizer manufacturers and the results of fertilizer inspection indicate the same thing, viz, that the mixing of cyanamid with acid phosphate will injure the fertilizer from the farmer's standpoint, and that if a considerable amount of the cyanamid is used in the mixture the fertilizer will be found on inspection to be decidedly deficient in available phosphoric acid.

Fertilizer analysis, E. A. MITSCHERLICH and W. SIMMERMACHER (*Landw. Jahrb.*, 43 (1912), No. 3, pp. 405-435; *abs. in Jour. Chem. Soc. [London]*, 104 (1913), No. 609, I, p. 812; *Chem. Zentbl.*, 1913, I, No. 18, pp. 1627, 1628).—In experiments with various phosphates on oats not only the yield but the phosphorus content of the crop followed the law of minimum as theoretically formulated by the author. The latter, therefore, proposes that the results of determinations of phosphoric acid soluble in a saturated solution of carbon dioxide be correlated directly with yields and not with the phosphorus content.

The different phosphates behaved very differently. With monocalcium phosphate there was an excess (*luxus*) consumption of phosphorus by the plant which is measured by the water solubility of the phosphate. The saturation concentration of the carbon dioxide solution with phosphate was dependent upon the temperature. The temperature of saturation must be kept as nearly as possible the same as that under which the plants grow in order that comparable results may be obtained. The author adopted 15° C. as most nearly meeting

this requirement. Of course seasonal variations make close approximations in this respect impossible, but the actual differences due to this factor are thought to be comparatively small.

A report on the phosphate fields of South Carolina, W. H. WAGGAMAN (U. S. Dept. Agr. Bul. 18, pp. 12, pls. 3, fig. 1).—The history of these deposits is briefly reviewed and their location, extent, character, and exploitation are described. "The phosphate region lies along the coast in a belt extending from the Wando River, in Charleston County, to the Broad River, in Beaufort County. The rock is of Tertiary age and is usually divided into two classes, namely, the land deposits and the river deposits. These classes, however, are practically identical, the latter being merely the former washed into the river beds. . . .

"With the exhaustion of the more accessible deposits and the discovery of higher grade phosphates in Florida and Tennessee, the output from South Carolina has fallen off considerably. River mining has entirely ceased, and only two companies are mining the land rock. The total output in 1911 was 169,156 tons. . . .

"The general opinion has been that the phosphates of South Carolina are practically exhausted. This is far from being the case. There are thousands of acres of rich phosphate land still practically untouched. Although the phosphate on much of this property is covered by a heavy overburden, more efficient mining methods and improved market and transportation conditions would render it all available."

Thomas slag, its preparation and use, J. P. WAGNER (Monatsber. Gesell. Förd. Wiss., Ackerb. u. Künste Unter-Elsass, 47 (1913), No. 3, pp. 126-168, figs. 27).—The process of manufacture of Thomas slag is described in some detail, and its use as a fertilizer is discussed.

Analyses of Thomas slag from different sources, H. VON FEELITZEN and I. LUGNER (Chem. Ztg., 37 (1913), No. 68, pp. 689, 690).—Analyses of a number of samples of Thomas slag are reported, showing a much smaller content of free lime than is indicated by the older analyses. There was no great variation in the composition of slag from different sources.

Kelp and other sources of potash, F. K. CAMERON (Jour. Franklin Inst., 176 (1913), No. 4, pp. 347-383, figs. 13).—This article discusses briefly other sources of potash, but deals in detail with the utilization of the Pacific coast kelps for this purpose. The more important species of kelps from the fertilizer standpoint, the location and extent of the kelp groves, the composition and fertilizing value of kelp, and methods of harvesting and handling the material are described. Data are also given as to the present status and future possibilities of the kelp industry on the Pacific coast.

Lime, B. H. HIRE (West Virginia Sta. Circ. 6, pp. 16, figs. 3).—This circular discusses in a popular way the effects of lime on the soil and gives information as to how it may be obtained and used.

On the influence of the ratio of lime to magnesia on plants, O. LOEW (Jour. Indus. and Engin. Chem., 5 (1913), No. 11, pp. 959, 960).—This is a reply to an article by Gile and Ageton already noted (E. S. R., 28, p. 812).

Is silica an indispensable constituent of plant food? M. LUNDIE (So. African Jour. Sci., 9 (1913), No. 10, pp. 263-268).—Earlier investigations on this subject are briefly reviewed and water culture experiments by the author are reported. The results of the latter indicated that silica is not essential as a plant food, but suggested that when deposited in the cell membrane and in the epidermis of the plant it might afford a certain protection against fungus disease (rust).

Commercial fertilizers, J. S. BURD (*California Sta. Bul.* 240, pp. 55).—Analyses and valuations of fertilizers inspected during the year ended June 30, 1913, are reported, and a list of registered fertilizer manufacturers and dealers in California for the year beginning July 1, 1912, is given. It is estimated that the sale of fertilizers in the State during the year ended June 30, 1912, was 50,955 tons. The indications are that the consumption during the year ended June 30, 1913, was much less than this.

AGRICULTURAL BOTANY.

On the chemical organization of the cell, W. RUHLAND (*Biol. Centbl.*, 33 (1913), No. 6, pp. 337-351).—Continuing work noted in a previous report on the permeability of the living plasma membranes (*E. S. R.*, 23, p. 37) the author here discusses the relation of the facts observed to the views of other investigators, a number of which are discussed.

The significance of the character of the electrical charge for the passage of colloids through the plasma membrane, W. RUHLAND (*Ber. Deut. Bot. Gesell.*, 31 (1913), No. 6, pp. 304-310).—Continuing the work noted above, the author states that no difference was established between acid and basic coloring matters as to conditions and rapidity of passage through living plasma membranes. Transpiration rate and electrical character have not been shown to be influential as regards rapidity of passage, and widely different plants show like behavior in these respects. These facts are held to support the author's view regarding the plasma membrane as an ultra-filter.

Investigations on the fermentation of some cyclic series compounds and the formation of the black material of humus, A. PERRIER (*Ann. Sci. Agron.*, 4. ser., 2 (1913), I, Nos. 5, pp. 321-350; 6, pp. 455-470).—The author presents the results of a study on the aerobic fermentation of benzoic, oxybenzoic, and phenic acids, and the rôle of cyclic compounds in the formation of the black coloring matter of manures and humus.

It was found that the cyclic compounds, particularly benzoic acid, which is rather widely distributed in the animal and vegetable kingdom, serve as nutrients for a large number of micro-organisms which are abundant in the soil.

A detailed study of the biochemical phenomena showed that benzoic acid is oxidized by *Bacillus pyocyaneus* and a number of other related organisms in a neutral medium to a black coloring material analogous to that in humus. The formation of this coloring matter is not considered due to tyrosinase, but should be rather compared to that which is produced in the oxidation of polyphenols, notably pyrogallol in an alkaline medium. This would indicate that the oxidation is brought about by the aid of an oxidase, but the author was unable to demonstrate the presence of a diastase associated with the phenomenon.

In the second part of the paper an account is given of an extended study of the formation of the coloring matter of manure and humus, which in every case is attributed to the oxidation in an alkaline medium of cyclic compounds contained in the manure or in plant materials in the process of decomposition.

A brief bibliography is appended.

The necessity of a bacterial association for the development of a myxobacterium, *Chondromyces crocatus*, E. PINOY (*Compt. Rend. Acad. Sci. [Paris]*, 157 (1913), No. 1, pp. 77, 78).—The author concludes from a study of *C. crocatus* that this organism is not able to accomplish its development apart from its association with a particular bacterium which is described and said to be closely allied to *Micrococcus latens*.

A mud sucking device for obtaining soil microflora and microfauna, B. PERFYL'EV (*Izv. Imp. St. Peterb. Bot. Sada (Bul. Jard. Imp. Bot. St. Petersb.)*,

13 (1913), No. 1-2 pp. 47-51, figs. 2).—Figures and a description are given of a convenient and cleanly device for obtaining mud and similar material in bottles for the study of the contained life forms.

Studies in Indian tobaccos.—III, The inheritance of characters in *Nicotiana tabacum*, GABRIELLE L. C. HOWARD (*Mem. Dept. Agr. India, Bot. Ser.*, 6 (1913), No. 3, pp. 25-114, pls. 25, fig. 1).—In a previous paper (*E. S. R.*, 23, p. 537), an account was given of a study of varietal characters and the isolation of pure forms of tobacco. In the present contribution additional data are presented relating to the behavior of different strains in later generations.

In the progress of the investigation it was found that parthenogenesis in *N. tabacum*, under the conditions of the experiment, is negligible. In all characters except height, the F_1 generation is intermediate between the parents. The limits of variation in the F_2 generation have been as great as those of both parents combined or have exceeded these in both directions. Selected variates of the F_2 generation gave cultures which differed in their range of variation from one another, and often from both parents. It was found that while the height of tobacco plants may differ only slightly, the factors on which such height depends may be almost entirely different. The number of leaves per plant was not found to depend on the height of the plant, and was also independent of the environment. A distinct segregation was observed as regards the arrangement of the leaves on the stem. The author states that the most suitable leaves for measurements are those occurring in the center of the plant, and that venation of the leaves is one of the most constant characters of the plant, parental forms having been reisolated in the third and fourth generations.

In conclusion the author summarizes the data, stating that "a study of the characters of *N. tabacum* shows that there is no inherent difference in the mode of inheritance of ordinary qualitative characters (such as the color of the corolla) and of those characters connected with the size of the organs which are subject to fluctuating variability. All the results obtained can be explained by the Mendelian assumption of segregation of characters, combined with the hypothesis that in connection with each character a large number of factors exist, each of which can be inherited independently."

The flowering of *Geranium robertianum* under the influence of various physical conditions, R. STÄGER (*Bot. Centbl., Beihefte*, 30 (1913), 1. Abt., No. 1, pp. 1-16; *abs. in Rev. Sci. [Paris]*, 51 (1913), II, No. 8, p. 245).—The flowering of this plant has attracted much attention on account of the apparent variation in its adaptation for pollination. The author claims that two types of flowers are produced, depending upon the climatic conditions at the time, protandrous flowers if the weather is fine and the temperature fairly high, and protogynous flowers in cooler and more humid surroundings. From 1 to 3 days are required for the pollination of the flowers. A high temperature and dry air favor precocious pollination, while low temperature and moist conditions retard it and favor the greater growth of the styles, resulting in a protogynous condition.

The relation between tuberization and infestation of the roots of *Spiranthes autumnalis* by endophytic fungi, C. BEAU (*Compt. Rend. Acad. Sci. [Paris]*, 157 (1913), No. 13, pp. 512-515).—A study was made of *S. autumnalis* in the light of the investigations of Bernard (*E. S. R.*, 14, p. 635; 18, p. 1031). The author found that while this orchid, which produces new tuberous organs each year, requires the presence of endophytic fungi to begin the development of its tubers, in a mature state it is independent of the symbiotic relationship.

Influence of radioactivity on vegetation, M. VACHER (*Bul. Soc. Nat. Agr. France*, 73 (1913), No. 5, pp. 357-372).—Discussing the results obtained from experimental work done by Petit and Ancelin (*E. S. R.*, 29, p. 326), Stoklasa (*E. S. R.*, 23, p. 731), and others, the authors state that radioactivity appears

to favor nitrification in soils and foliar development of plants. Soil naturally or artificially supplied with nitrogen, phosphoric acid, potassium, and lime is always improved by the presence, even in minute quantity, of radioactive substance.

Some recent studies on germination, E. LEHMANN (*Ztschr. Bot.*, 5 (1913), No. 5, pp. 365-377).—This is a brief account of studies on the factors influencing germination, with references to several recent articles.

Germination of potato, E. COUVREUR (*Compt. Rend. Soc. Biol. [Paris]*, 74 (1913), No. 23, pp. 1315-1317).—As the result of a study of potatoes during germination, the author states that both maltose and a ferment are present from the beginning of that process, the latter being active in all tissues after a certain age is attained. It is stated that analogous facts have been noted in case of beans and chestnuts, and that publication of these is contemplated.

Transpiration and osmotic pressure in mangroves, F. C. VON FABER (*Ber. Deut. Bot. Gesell.*, 31 (1913), No. 6, pp. 277-281).—The author states, as the result of his studies, that the high osmotic pressure in the cells of mangroves is due to the storing of salts and other osmotically important substances, in some cases probably tannic acid. Such accumulation is not a function of transpiration but a specific character of the plant, as held by Fitting (E. S. R., 25, p. 430) to be true of desert plants.

The distribution of temperature in living plants, G. DUPONT (*Rev. Gén. Sci.*, 24 (1913), No. 11, pp. 418-425, figs. 15).—This is essentially the same article as previously reported (E. S. R., 28, p. 126).

Wind and the plant world; a study, G. H. KROLL (*Bot. Centbl., Beihefte*, 30 (1913), 1. Abt., No. 1, pp. 122-140).—This is a discussion of the direct and the indirect influence of wind on plant life in or near large bodies of water or on continental areas, including in the former case wave action, nutritive or noxious solutions, seed transportation, etc., and in the latter case injury in exposed situations through breakage, increased transpiration, etc., or furtherance through such agents as seed distribution and rain production.

The presence and persistence of hydrocyanic acid in some grains in hot regions, L. RAYBAUD (*Compt. Rend. Soc. Biol. [Paris]*, 74 (1913), No. 19, pp. 1116, 1117).—It is stated that studies with 26 varieties of sorghum in north and west Africa and India, and 2 species of Eleusine in India, have shown that even under conditions of irrigation, etc., unfavorable to its accumulation, hydrocyanic acid occurs in considerable quantity in the young plants and that later it migrates to the higher portions where it may be found until the maturation of the grain, after which it slowly disappears. This result is regarded as corroborative of the conclusion reached by Treub (E. S. R., 23, p. 330) regarding the rôle played by hydrocyanic acid in plant growth.

Demonstration and localization of nitrates and nitrites in plants, R. KLEIN (*Bot. Centbl., Beihefte*, 30 (1913), 1. Abt., No. 1, pp. 141-166, pls. 2).—The author reports that nitric salts are usually found in herbaceous plants. Nitrites were not found in the sap of Fuchsia as exuded under root pressure, but they develop apparently as the result of bacterial and fungal activity. They do not appear ordinarily in underground portions of *Sagittaria sagittifolia* and *Pisum*. They are demonstrable in potato tubers only before sprouting, but they are found in expressed leaf sap of *Erythrina* and in root nodules of some Leguminosæ, being quite abundant in case of *Phaseolus multiflorus*.

A bibliography is given.

On the alleged connection between assimilation of nitric acid and deposit of manganese in plants, ELSA HOUTERMANS (*Sitzber. K. Akad. Wiss. [Vienna]*, *Math. Naturw. Kl.*, 121 (1912), I, No. 8, pp. 801-831, pls. 2).—The author, giving tabulated results of some recent investigations, states that she was unable

to confirm the conclusions of Acqua (E. S. R., 29, p. 323), which are to the effect that the points of deposit of certain metallic ions in growing regions are also points of utilization of the acid portions of the nutritive compounds involved.

In case of wheat and beans the deposit of manganese occurred when this cation was united with an indifferent or injurious anion, if nitrate in other and harmless form was supplied to the plant, the rate and amount of manganese deposit proving independent of nitrogen assimilation. The blackening was independent of light admission and is probably explainable as related to enzymatic processes. The deposit of manganese dioxid in case of *Elodea canadensis* occurred only in light and apparently was not due in this case to nitrogen assimilation. The deposit of manganese failed only when the endodermis was continuous and unwounded, or when the epidermis acted as a chemical filter. On employment of low concentrations of toxic substances or of very concentrated nutritive media, the inner endodermis thickened in case of all plants studied which possessed uninterrupted endodermis. Distilled water had the same effect on the endodermis as did a weak poison, while various strong poisons able to check growth caused no such thickening of endodermis. Potassium permanganate was reduced commonly in the outer layers of cells, otherwise always in the third or fourth layer, never reaching the vascular bundle cylinder proper.

The significance of deposits occurring in plants cultivated in solutions of manganese salts, C. ACQUA (*Ann. Bot. [Rome]*, 11 (1913), No. 3, pp. 467-471).—This is a critical note in reply to the above article.

On the presence of deposits in plant tissues due to culture in manganese nitrate solution, EVA ROSELLI (*Ann. Bot. [Rome]*, 11 (1913), No. 3, pp. 459-465).—Results obtained from the study of 11 plants covering a wide range of forms are said to confirm the conclusions arrived at by Acqua (E. S. R., 29, p. 323), but to be at variance with those reached by Houtermans noted on page 30. It is stated that a close relation appears to exist between the deposit of cations and the changes occurring in newly formed tissue.

The influence of calcium, magnesium, and potassium nitrates upon the toxicity of certain heavy metals toward fungus spores, L. A. HAWKINS (*Physiol. Researches*, 1 (1913), No. 2, pp. 57-92, figs. 6).—The results of a study of the influence of one salt in altering the toxic effect of another upon fungus spores are given. The salts employed were the nitrates of copper, lead, zinc, nickel, and aluminum used alone and in combination with the nitrates of calcium, magnesium, and potassium.

It was found that the effect of a toxic salt on the germination of the conidia of *Glomerella cingulata* might be influenced by the addition to the medium of calcium, magnesium, or potassium nitrate. This effect, it is claimed, is not due to a depression of ionization of the toxic salt nor to the formation of undissociated double salts, but the influence of calcium upon the toxicity of the salts of the heavy metals employed is to be referred to an effect of the calcium nitrate on the spore or on the contained protoplasm.

A bibliography is appended.

Experiments on the action of sodium sulphate as affecting growth of plants, E. HASELHOFF (*Landw. Jahrb.*, 44 (1913), No. 4, pp. 641-650).—Discussing the results of former investigations on the effect of flue dust (E. S. R., 19, p. 1130; 21, p. 128) and in connection therewith his more recent studies regarding the action of sodium sulphate on growing beans, barley, and Indian corn, the author claims that in spite of individual variations it is safe to conclude that sodium sulphate in 0.05 per cent strength, while sometimes hastening development, usually decreases the total growth of the plants studied as estimated by weight, the growth in length proving unreliable in this respect. The soil-culture studies indicated an injurious effect of sodium sulphate on

plant growth, also that in the crop an increase of sodium and of sulphuric acid corresponded to an increase of sodium sulphate in the soil or the nutritive solution employed.

The distribution of atmospheric impurities in the neighborhood of an industrial city, C. CROWTHER and D. W. STEUART (*Jour. Agr. Sci. [England]*, 5 (1913), No. 4, pp. 391-408, figs. 2).—In continuation of a previous report (E. S. R., 25, p. 434) an account is given of an examination of the atmosphere in the country surrounding the city to a distance of about 7 miles.

The observations here reported show that no general effect upon the opening of the buds could be detected. By the end of May smoke damage began to be evident within 2 miles of the center of the city by the appearance on the leaves of sycamores and limes of characteristic brown blotches. During June the conditions, so far as the leaves were concerned, became considerably worse, and in the case of many trees, as shown by the examination of cross sections, there was very little annual growth. Criticisms having been made of previous observations relating to the clogging of the stomata, microscopical examinations were made of a number of evergreen leaves which confirmed in the main the previous statements.

Summarizing the results observed, the authors state that the sulphur content of the rain falling at a given station affords a fairly reliable diagnosis of the degree of pollution of the atmosphere by smoke providing the observations be prolonged over several months. The rain analyses show further that appreciable smoke pollution remains throughout the agricultural area at distances of 7 miles from the city, the rate of improvement being slower in the direction of the prevailing winds than in other directions.

The influence of tar, particularly that of tarred streets, upon vegetation, P. CLAUSSEN (*Arb. K. Biol. Anst. Land. u. Forstw.*, 8 (1913), No. 5, pp. 493-514, pls. 2, figs. 8).—As the result of experimentation with 5 ornamental flowering herbs, 2 firs, and a spruce, exposed to fumes of several commercial tars in air or soil, the author states that the various kinds of tar sold for highway building purposes differ widely as to effect on the plants; that the injurious effects of tar vapors are closely related to their concentration, this depending upon volatility and temperature; and that species of plants differ widely as to their sensitivity to such vapors.

It is recommended that the plants be placed at a safe distance from the tarred surfaces; that careful tests be made of tars intended for such purposes; that the practice of heating the tar in the neighborhood of the plants be avoided, also that as low temperatures as are practical be employed; and that this work be done so far as possible when the foliage is off the trees, and by no means during the very early stages of its formation.

FIELD CROPS.

Study of farm practice versus field experiments, W. J. SPILLMAN (*Proc. Soc. Prom. Agr. Sci.*, 33 (1912), pp. 103-113, figs. 3).—This article has been previously noted (E. S. R., 28, p. 198).

Determination of probable error in field experiments, HARNOTH (*Mitt. Deut. Landw. Gesell.*, 28 (1913), Nos. 5, pp. 70-73, fig. 1; 6, pp. 87-90; 7, pp. 105-107).—This paper includes discussions of methods of reckoning the variation of each check plot of a series from the mean of their yields. For this

purpose Gauss' formula, $R = \pm \frac{0.845[lv]}{\sqrt{n[n-1]}}$ is used, in which lv is the sum of the variations regardless of signs, n the number of observations, and 0.845 is a

constant. Applications of this formula to various fertilizer experiments are presented.

Determinations of probable errors in field experiments, I. ALEXANDROWITSCH (*Mitt. Deut. Landw. Gesell.*, 28 (1913), No. 18, pp. 268-271).—This is a critical discussion of the above.

Determination of probable errors in field experiments, HARNOTH (*Mitt. Deut. Landw. Gesell.*, 28 (1913), No. 19, pp. 281-283).—This is a discussion of the above two articles.

Methods of testing varieties, E. KOSTECKI (*Trudy Būro Prikl. Bot. (Bul. Angew. Bot.)*, 5 (1912), No. 7, pp. 177-204, figs. 3).—The first part of this article discusses field methods and the results obtained. The second part considers sources of error in computing and comparing results. The probable error to be reckoned with in an experiment (e) was obtained by extracting the square root of the sum of the square of the apparent errors (v) divided by the number of observations (n) minus 1. The formula is expressed as $e = \sqrt{\frac{\sum v^2}{n-1}}$.

Variety tests of field crops, O. LEMMERMANN ET AL. (*Landw. Jahrb.*, 42 (1912), No. 5, pp. 679-699).—Results are given of tests of numerous varieties of winter rye, winter and spring wheat, oats, field beets, field carrots, and alfalfa. Data are presented in tabular form including meteorological observations.

Electroculture, J. ESCARD (*Rev. Gén. Sci.*, 24 (1913), No. 8, pp. 302-309, figs. 5).—The author gives a survey of the work done along this line since its inception about 1845, including methods and general results.

Observations on some new methods of growing cereals, T. REMY and E. KREPLIN (*Landw. Jahrb.*, 42 (1912), No. 2, pp. 597-629, fig. 1).—This work gives the results of observations on the effect of transplanting to different depths, hilling up transplanted plants, seeding in furrows, and hilling up plants in ordinary field culture, with winter rye, winter wheat, spring wheat, barley, and oats, with special reference to the Demtschinsky method (*E. S. R.*, 27, p. 232; 28, p. 632).

It is noted that great care seemed necessary in seeding with less than the customary quantity of seed, although when this could be done the improved vigor and size of the individual plants commended this practice.

With winter wheat, winter rye, and spring barley the planting in furrows which were later filled in with soil was slightly favorable, but with spring wheat and oats the injury caused by the frit fly was more marked when the soil came higher up on the stem than normal.

All of the cereals showed improved growth by the Demtschinsky method, but spring cereals were more readily damaged by the frit fly. The hand labor involved in this transplanting method made it impractical as a field method.

Dominant and recessive characters in barley and oat hybrids, R. W. THATCHER (*Proc. Soc. Prom. Agr. Sci.*, 33 (1912), pp. 37-50).—These experiments, which were conducted at the Washington Experiment Station, have shown that "the percentages of proportionate distribution of the various groups, when computed on the basis of spring types, show clearly the dominance of hooded over bearded, and of 2-rowed over 6-rowed, characters as noted in preceding crosses. The distribution of 2-rowed, hybrid, and 6-rowed types in both the hooded and bearded classes, showing the characteristic 1:2:1 Mendelian ratio and the 26.6 per cent bearded types as compared with 73.4 per cent hooded types, furnishes confirmatory evidence that this is a unit pair character."

With oats it is noted that no definite conclusions could be drawn from the results of crossing with Chinese Hull-less. "The appearance of black kernels in the progeny from a cross of 2 white-kernelled parents indicates heterozygosity in 1 or both parent strains, which, however, does not seem to have a consistent effect in the various crosses. . . . In one of the crosses there is evidence of a Mendelian ratio between the hulled and hull-less character, but in others such a proportional distribution is wholly lacking."

[Fertilizer experiments], A. W. K. DE JONG (*Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Agr. Chem. Lab., 1913, No. 3, pp. 1-49*).—In fertilizer experiments with rice, cassava, soy beans, maize, and peanuts, better results were obtained with maize with double superphosphate than with Thomas slag or guano. The results with bone meal were even better than with the double phosphate, while barnyard manure seemed to lack the phosphorous to produce the maximum yields. Cassava responded best to nitrogen. Peanuts were apparently benefited by barnyard manure plus bone meal. In general the phosphates seemed to give the best results.

Progress report of cooperative irrigation experiments at California University Farm, Davis, California, 1909-1912, S. H. BECKETT (*U. S. Dept. Agr. Bul. 10, pp. 21, figs. 7*).—These experiments were for the purpose of determining the water requirements of various standard crops.

With alfalfa, the results indicated that in open, well-drained soil, typical of that found in the floor of the Sacramento Valley, the general tendency is toward an increase in yield of alfalfa with the increased amounts of water applied up to at least 48 in.; and for such conditions as are found on the university farm the limit beyond which the increase in yield will not pay for increased cost of applying the water is in the neighborhood of 30 in.

"Without irrigation spring-sown alfalfa is uncertain in Sacramento Valley, and under conditions of normal rainfall and moderate climate not more than one-half of the stand can be expected to survive through the summer. Heavy spring irrigations, when followed by long periods throughout the summer without water, did not benefit alfalfa. Examination of the root growth under these conditions shows that water applied to the little plants in the early spring produces a root growth outwardly along the surface of the soil rather than downward, and when this is followed by long dry periods, the soil drying out leaves the young plant stranded above the moisture zone. Far better results were obtained by delaying irrigation until the root growth was well established, and even until the little plants seemed to be stunted and suffering for moisture. . . . Late and very late summer irrigations tend to produce sturdier plants and heavier yields the following summer. After the root growth is well established, the growth may then be forced by frequent and, if the soil will stand it, heavy irrigations."

In studying the best time to irrigate alfalfa it was found that 2 applications between cuttings gave larger yields and kept the plants in better condition than when the same amount of water was applied in one irrigation, either just before or just after each cutting, but it was concluded that the extra yield was not large enough to make it a profitable method.

In the case of barley, 3 years of irrigation experiments showed that the application of water always gave a profit and that a late application gave better yields than an early one. The results of irrigating maize for 1910 and 1911 showed little advantage due to irrigation, although in 1910 there was a slight profit with 1 and 2 applications of water. The cost of irrigating from 1 to 3 times during these 2 seasons ranged from \$1.40 to \$3.90 per acre with the furrow method. Similar results were obtained with White Durra sorghum, but

it is noted that with both these crops irrigation can be made to pay if great care and intelligence be exercised.

The yields of oats and wheat following alfalfa were produced at a profit by irrigating in 1912, the grain values ranging from \$18.15 to \$30.60, as compared with \$6.53 and \$8.40 without irrigation. Sugar beets following alfalfa in 1912 gave increased yields with an increased water supply, while the sugar content slightly decreased. Better yields were obtained under irrigation with early than with late seeding. With the early seeding the crop had a value of \$54.25 when not irrigated, while with 2 irrigations it was \$87.50.

The reseeding of depleted grazing lands to cultivated forage plants, A. W. SAMPSON (*U. S. Dept. Agr. Bul. 4, pp. 34, pls. 8, figs. 4*).—In this bulletin the range problem and investigations of these problems in the National Forests are briefly discussed, and studies reported continuing previous work (E. S. R., 22, p. 35). The following grasses were used in over 500 experiments in 1909, 1910, and 1911; Hard fescue (*Festuca duriuscula*), broom grass (*Andropogon* sp.), Canada blue grass (*Poa compressa*), slender wheat grass (*Agropyron tenerum*), blue grama grass (*Bouteloua oligostachya*), Italian rye grass (*Lolium italicum*), smooth or Hungarian brome (*Bromus inermis*), Kentucky blue grass (*P. pratensis*), mesquite (*Hilaria cenchroides*), orchard grass (*Dactylis glomerata*), perennial rye grass (*L. perenne*), redtop (*Argostis alba*), tall meadow oat grass (*Arrhenatherum elatius*), and timothy (*Phleum pratense*). The following nongrasses were also used: Alfalfa (*Medicago sativa*), alfilaria (*Erodium cicutarium*), alsike clover (*Trifolium hybridum*), bur clover (*M. denticulata*), Japanese clover (*Lespedeza striata*), red clover (*T. pratense*), Australian saltbush (*Atriplex semibaccata*), and white clover (*T. repens*). By far the best results were secured with timothy, 64.37 per cent being at least partially successful. Smooth brome grass and perennial rye grass ranked next. Very few of the nongrasses yielded satisfactory returns, the best results being with white and alsike clovers and alfilaria.

In studying the different cultural methods employed with timothy, redtop, and Kentucky blue grass, a light brushing to cover the seed was found to give better results than tramping with sheep, or no treatment. The altitude of the area planted formed an important element in reseeding. The yield at 4,800 ft. was about 4 times that at 7,800 ft., and the difference in the viability of the seed produced was even greater. Autumn seeding proved superior to spring seeding. The cost of reseeding with a mixture of timothy, Kentucky blue grass, and redtop ranged from 80 cts. to \$3.50 per acre, but usually averaged about \$1.50.

"The reseeding investigations show that the returns secured from sowing suitable cultivated forage plants on certain ranges fully warrant the expense. It is not to be presumed, however, that all overgrazed ranges can be successfully reseeded to cultivated plants. On the contrary, it is unquestionably true that existing conditions in the major portion of the native grazing lands are antagonistic to the establishment of introduced plants. This is due primarily to one or all of 3 conditions: Excessive elevation, poor soil, coupled with insufficient moisture, or too much and too aggressive native vegetation."

A note on two textile plants from the Belgian Kongo, E. MESTDAGH (*Bul. Agr. Congo Belge, 3 (1912), No. 3, pp. 619, 620, figs. 2; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 3 (1912), No. 12, pp. 2639, 2640*).—Two new fiber plants, akonge (*Triumfetta semitriloba*) and losa (*Manniophyton africanum*), are here described.

Alfalfa seed production, P. K. BLINN (*Colorado Sta. Bul. 191, pp. 3-16, figs. 13*).—This bulletin is a report of progress in work which was instituted

because of the general decrease in production and yield of alfalfa seed of recent years in Colorado. It discusses the following factors as influencing seed production: Vegetative growth, moisture supply, climatic conditions, insects, and diseases. It is noted that continued irrigation for a long series of years has so influenced the subsoil moisture content as to make it unfavorable to seed production. The methods which were tried to improve the seed-producing characters of alfalfa were seed selection, row cultivation, and control of moisture by light row irrigation, all of which proved beneficial.

Alfalfa management in Iowa, H. D. HUGHES (*Iowa Sta. Bul.* 137, pp. 72, figs. 33).—This bulletin gives directions and suggestions for the production of alfalfa on the various soil types of the State. Reports are given of the experiences of practical farmers in all parts of the State, covering 1,016 alfalfa seedings, of which only 12.7 per cent were classed as failures. The most successful results were reported from Missouri loess and moraine soils, and the greatest number of failures on the Iowa drift and the southern Iowa loess areas. Some of the factors which seemed to be responsible for the failures were lack of proper drainage, necessary bacteria, sufficient plant food, or sufficient moisture to germinate the seed; too heavy or compact soil; young seedlings smothered by weeds and by nurse crops; seeding too deep; a packed surface; poor seed; insect pests; and fungus diseases.

Special note is made of the need of sufficient plant food in the soil at seeding, and of liberally applying barnyard manure on these soils.

Experiments with Turkestan alfalfa in Hungary, J. GYARFAS (*Kisérlet. Közlem.*, 15 (1912), No. 2, pp. 191-209).—Trials of Turkestan alfalfa in various localities showed it to be much inferior to the native alfalfa in drought and frost resistance, and vegetative energy. It also had a much shorter vegetative period, which allowed the growth of weeds and grasses.

A new two-rowed winter barley, D. NEUMANN (*Wehnschr. Brau.*, 29 (1912), No. 37, pp. 526-528, figs. 3).—Through crossing a 4-rowed Mammoth winter barley with a 2-rowed summer barley that had been artificially carried through the winter, a hardy 2-rowed winter barley resulted. By the application of Mendel's law this variety proved stable. It produced well, and was a product of excellent brewing qualities.

A mutation in a pure line of *Hordeum distichum*, L. L. KIESSLING (*Ztschr. Induktive Abstam. u. Vererbungslehre*, 8 (1912), No. 1-2, pp. 48-78).—This gives in detail the characteristics of a barley that appeared in a Bavarian variety, and is considered a mutation.

Variation studies in brome grass, A. KEYSER (*Colorado Sta. Bul.* 190, pp. 3-20, figs. 19).—This bulletin reports the progress of work in studying the strains of awnless brome grass (*Bromus inermis*) which have been collected at the station and which seem especially well adapted to Colorado conditions. There are now under observation 121 strains of this grass, and these show a wide range of individuality in habits of growth and coloration. Variations occur in tillering habit, height of leaf mass, total height of plant, and vigor of stolonification, while the colors range from bright yellow green to a very dark green. Most of these types bred true from seed, but the progeny of some showed wide variation. It was shown that this grass could be propagated vegetatively.

On the presence of hydrocyanic acid in white clover, M. MIRANDE (*Compt. Rend. Acad. Sci. [Paris]*, 155 (1912), No. 15, pp. 651-653; *abs. in Internat. Inst. Agr. [Rome]*, *Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 12, p. 2637).—Methods are described by which hydrocyanic acid was discovered in white clover (*Trifolium repens*).

Silver King.—A corn for northern Iowa, H. D. HUGHES (*Iowa Sta. Bul.* 138, pp. 75-95, figs. 11).—This bulletin gives the development and early history of Silver King corn and sets forth its exceptional value for cultivation in northern Iowa. Records obtained from growers in Wisconsin, covering a period of 5 years, show an average yield of 59.2 bu. per acre, which is an average of 10.9 bu. more than other varieties. This pedigreed corn has been produced at the Iowa Station and about 150 bu. will be distributed among farmers of northern Iowa.

Corn culture in North Carolina, J. L. BURGESS (*Bul. N. C. Dept. Agr.*, 33 (1912), No. 6, Sup., pp. 34).—This bulletin discusses the black, gray, red, and mountain soils of the State in their connection with corn production, green manuring, conservation of moisture, selection and preparation of the seed, planting, cultivating and harvesting, rotations, corn judging, and varieties.

In the variety tests those giving the best results in the coastal plains were Cocke Prolific, Biggs Seven-ear, Southern Beauty, and Hickory King; and in the Piedmont section, Weekly Improved, Southern Beauty, and Cocke Prolific.

Notes on corn growing in Guam, J. B. THOMPSON (*Guam Sta. Rpt.* 1912, pp. 22-24).—The primitive methods of planting and harvesting corn followed by the natives in Guam are described. It is noted that a yield of 27.75 bu. per acre was obtained at the station, which was better than the average crop grown in Guam.

Notes are given on variety tests that include over 40 varieties of widely varying types originating in India, Ceylon, Burma, Formosa, Ecuador, and Colombia. The small-grained types from southern Asia required from 200 to 220 kernels to weigh 1 oz. while a variety from Ecuador required only 55 kernels. No. 576, a variety from the island of St. Vincent, is noted as having characteristics, notably early maturity, making it especially suited to Guam conditions.

Twelfth annual report of the Indiana Corn Growers' Association, edited by G. I. CHRISTIE (*Ann. Rpt. Ind. Corn Growers' Assoc.*, 12 (1912), pp. 94, figs. 22).—This report includes addresses on alfalfa by A. P. Grout, A. T. Wiancko, J. N. Dyer, and M. Douglas, on corn by P. E. Goodrich and D. F. Maish, and on vetch by M. L. Fisher.

Fourth annual report of the Ontario Corn Growers' Association, J. S. DUFF (*Ann. Rpt. Ontario Corn Growers' Assoc.*, 1911, pp. 34, figs. 16).—This includes addresses on corn growing for profit, silage feeding, the improvement of the corn crop, and alfalfa as a soil builder.

Rubelzul cotton: A new species of Gossypium from Guatemala, F. L. LEWTON (*Smithsn. Misc. Collect.*, 60 (1912), No. 4, pp. 2, pls. 2).—This is a description of *Gossypium irenæum*, found a few miles from Senahú in Alta Verapaz, Guatemala. Its most prominent feature is the remarkable development of the calyx, which reaches proportions not known in any other species.

The cotton of the Hopi Indians: A new species of Gossypium, F. L. LEWTON (*Smithsn. Misc. Collect.*, 60 (1912), No. 6, pp. 10, pls. 5).—This publication gives an account of the history and a technical description of *Gossypium hopi* n. sp. and its uses by the Pima and Hopi Indians.

Experiments on the retting of flax, M. RINGELMANN (*Bul. Mens. Off. Renseig. Agr.* [Paris], 11 (1912), No. 9, pp. 1175-1182; abs. in *Internat. Inst. Agr.* [Rome], *Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 12, pp. 2638, 2639).—A bacteriological process is described, by means of which the retting of flax may be carried on in severe winter weather with good results.

Potassium fertilizer for hops, D. NEUMANN (*Wehnschr. Brau.*, 29 (1912), Nos. 48, pp. 679-682; 49, pp. 691-694).—In 12 cooperative experiments the

average increase in yield was from 20 to 30 per cent after the use of potash, but the effect on the quality of the product was doubtful.

Seed varieties of *Lupinus angustifolius* and *L. luteus*, B. KAJANUS (*Ztschr. Induktive Abstam. u. Vererbungslehre*, 7 (1912), No. 3-4, pp. 235-239, pl. 1).—The author describes his method of separation by color marking on the seeds from yellows and blues. Five types of *L. angustifolius* and 3 of *L. luteus* were segregated and bred true. It was noted that black was dominant over normal colors.

African manioc, HENRY, YVES, and P. AMMANN (*Agr. Prat. Pays Chauds*, 12 (1912), No. 110, pp. 353-368, figs. 3; abs. in *Internat. Inst. Agr. [Rome]*, *Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 8, pp. 1769-1771).—This article describes the cultivation of this root crop and the manufacture of its products, flour, glucose, and alcohol.

Vegetative experiments with 88 varieties of oats, G. SCHNEIDER (*Landw. Jahrb.*, 42 (1912), No. 5, pp. 767-833, pl. 1, figs. 20).—In this work the root systems were especially studied as a factor bearing directly upon crop production.

The above ground parts ranged from 18.1 to 54.3 per cent of the root weight, averaging 29.9 per cent at the time of heading and from 10.6 to 28.3 per cent at harvest time, with an average at the latter period of 17.3 per cent. It is noted that the largest yield of grain was not due to more rapid development in germinating, growing, or maturing, or to a longer vegetative period, but to the large functioning capacity of the variety. The early ripening varieties as a rule gave better yields than the late. The percentage of glume to kernels followed inversely the functioning ability of the root and the length of the vegetative period. The larger the spikelet and the higher it was placed on the panicle the heavier as a rule were its kernels found to be.

A study of the weight of the differently placed kernels on the panicle showed those on the base of the spikelet to be the lightest. The average relation of the outer kernel to the inner on the spikelet was as 100:66.4, and to the middle as 100:30.9. The inner and middle kernels were never found to have awns.

A bibliography is appended.

Breeding and seed production of the Fichtel Mountain oats, RAUM (*Landw. Jahrb. Bayern*, 2 (1912), No. 11, pp. 841-940, figs. 14).—This gives the history, description, and methods employed since 1895 in the breeding of this variety of oats.

Wild plantain fiber from India (*Bul. Imp. Inst. [So. Kensington]*, 10 (1912), No. 4, pp. 536, 537).—It is noted that a strong fiber from 4 ft. to 5 ft. 6 in. in length was manufactured from a species of the wild plantain.

Variety [and manurial] tests of potatoes, A. L. DACY (*West Virginia Sta. Rpt.* 1912, pp. 31-54, figs. 3).—This paper records results of variety and fertilizer tests of potatoes conducted at Reedsville, Long Reach, Terra Alta, Letart, and Salama. This work was begun in 1905 and continued with more or less irregularity through 1912.

The average yield of merchantable tubers of the best 10 varieties for the 7 years' trial ranged from 91.5 to 116.8 bu. per acre. The effect of altitude was noted and 7 varieties are named and recommended for high altitudes. Twenty-two varieties are described and typical tubers of 35 varieties are pictured.

As results of the fertilizer tests it is noted that "in amounts up to 500 lbs. per acre it does not pay to apply even a high-grade fertilizer broadcast; that the same amount (500 lbs.) applied in the furrow at planting time produces a very profitable increase in the crop . . . and that in most seasons it is profitable to apply 1,000 lbs. to the acre, putting 500 lbs. in the furrow and applying 500 broadcast."

Pointers on the growing and selection of types of eating potatoes, W. SCHIFTAN (*Illus. Landw. Ztg.*, 33 (1913), No. 14, pp. 111, 112, figs. 7).—In this article 7 types of eating potatoes are described and illustrated and their characteristics discussed. A distinction is made between these types and those grown for brewing or the manufacture of alcohol, starch, etc.

Experiments in the defoliation of sugar beets, F. STROHMER, H. BRIEM, and O. FALLADA (*Österr. Ungar. Ztschr. Zuckerindus. u. Landw.*, 41 (1912), No. 2, pp. 228-240).—This reports a series of experiments in which the yield and sugar content of beets from which the first 2 rows and the first 3 rows of leaves were removed at 3 stages of development, August, September, and October, were compared with those from normally developed plants. In each case the decrease in both sugar content and total yield was in proportion to the quantity of leaves removed. Tabulated analyses of the roots of the several series are given.

Small beet seed, H. BRIEM (*Bl. Zuckerrübenbau*, 19 (1912), No. 12, pp. 185-187).—An article in which the author discusses the value of color, odor, and size of the beet seed, and points to investigations showing that small seeds are not inferior to large ones.

The size of the seed ball of beets, H. PLAHN-APPIANI (*Bl. Zuckerrübenbau*, 19 (1912), No. 17, pp. 265-267).—This is a discussion with citations showing the equal value of large and small seed balls in beet production.

The value of bees to seed beet growing, E. VASILIEFF (*Bl. Zuckerrübenbau*, 19 (1912), No. 10, p. 155; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 8, p. 1773).—This article describes the important part bees play in the production of beet seeds.

The manuring of sugar cane at Samalkota Agricultural Station, 1902-1912, G. R. HILSON (*Dept. Agr. Madras Bul.* 66, 1913, pp. 8).—This work shows that on the Delta lands commercial fertilizers are not to be recommended, and that with the price of castor-cake about 4 times that of margosa and pungam cake, the latter is the more economical manure. The yields ranged from 2,767 to 7,167 lbs. raw sugar per acre.

The culture of flue-cured tobacco, E. H. MATHEWSON (*U. S. Dept. Agr. Bul.* 16, pp. 36, figs. 12).—In this bulletin the author has outlined the Old Belt and the New Belt sections for the cultivation of this class of tobacco, and has given a historical sketch leading up to the present time methods of flue-curing tobacco. In describing methods of cultivation, the importance of humus in the soil is noted, and it is stated that the humus may be obtained by plowing under timothy and redtop sod. Other crops mentioned in this connection are oats, wheat, cotton, peanuts, sweet potatoes, corn, and cowpeas, the legumes of which may be pastured off with hogs. Various methods of fertilizing, including the use of barnyard manure and lime, are discussed, and formulas for both sections are presented. Further discussions include varieties, selection and care of plants, preparation and care of the seed bed, comparison of early and late planting, transplanting, cultivation, diseases, insect enemies, topping and suckering, harvesting, and curing and handling. Descriptions are given of curing barns and storage houses.

The entire cost of producing and marketing flue-cured tobacco is estimated at from 6 to 10 cts. per pound.

The Utelo, a plant with oleaginous seeds, E. MESTDAGH (*Bul. Agr. Congo Belge*, 3 (1912), No. 3, pp. 645, 646, fig. 1; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 12, pp. 2640, 2641).—A cucurbit native to the Belgian Congo, from the seed of which oil may be extracted, is described, as is also the aboriginal method of manufacture.

On the selection of a type of wheat resistant to severe winters, V. KOLKUNOV (*Khozŭaistvo* 7 (1913), No. 36, pp. 1161-1167; *abs. in Internat. Inst. Agr. [Rome]*, *Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 12, pp. 2631-2634).—In subjecting numerous varieties of growing wheat to low temperatures and excessive coverings of snow, the xerophytic varieties seemed the most hardy.

Portuguese varieties of wheat and their improvement, O. KLEIN (*Landw. Jahrb.*, 42 (1912), No. 2, pp. 331-364, pls. 8).—This article gives results of trials of some foreign as well as domestic varieties conducted at Lisbon.

It was found that in general seeding with the drill at the rate of 15 kernels per square meter, or broadcast from 200 to 250 kernels per square meter gave the best results.

Complete chemical analyses and yields per hectare of the grain and straw are given for 30 varieties, with botanical descriptions, notes, etc., for each variety. The weight of 100 kernels ranged from 3.7 to 6.4 gm. and of 1 liter from 720 to 833 gm. The specific gravity varied from 1.294 to 1.390.

Clover and grass seeds, with reference to valuation, and the present status of their production and trade from the local standpoint, A. BOERGER (*Landw. Jahrb.*, 42 (1912), No. 1, pp. 1-118, pls. 18).—In a discussion concerning seeds from various countries and localities it is noted that in general, in so far as investigations have been made, seeds have produced better when grown in the locality where planted.

Considerable space is devoted to the discussion of means of forming and operating organizations to promote the production, use, and trade in a high quality of grass and clover seeds. Tables give data regarding foreign trade in seeds and the home supply and demand.

Seed tests, L. HILTNER ET AL. (*Landw. Jahrb. Bayern*, 2 (1912), No. 9, pp. 636-664).—An article in which results of germination and purity tests of clover and grasses from European sources are given and discussed.

HORTICULTURE.

Garden farming, L. C. CORBETT (*Boston, Chicago, and London*, 1913, pp. X+473, figs. 175).—A practical treatise on the intensive and extensive culture of vegetables in which the author presents in considerable detail the results of his own observations and investigations, together with those of other horticultural authorities.

The successive chapters of part 1 discuss vegetable gardening, or olericulture; the soil as a factor in the work of the market gardener; principles of planting and cultivation; forcing and forcing structures; root cellars and storage houses; transportation of truck crops; precooling and cold storage of vegetables; and the home vegetable garden. In part 2 the commercial vegetables are arranged in alphabetical order and considered with reference to their development, cultivation, and uses.

Pomology, horticulture, and viticulture, E. REIMERS (*Jahresber. Landw.*, 27 (1912), pp. 229-250).—A review of recent contributions to the knowledge of pomology, horticulture, and viticulture in Germany.

Report of field work by the horticultural department during 1911, A. L. DACY (*West Virginia Sta. Rpt. 1912*, pp. 78-97, figs. 13).—This report reviews cooperative spraying and pruning demonstrations conducted in different sections of West Virginia during 1911. Some suggestions are also given relative to the possibilities of truck growing in the State. As a result of orchard demonstrations greatly increased returns have been reported by the owners.

[Fruit trees in Paraguay], G. T. BERTONI (*Agronomia [Puerto Bertoni]*, 5 (1913), No. 5-6, pp. 185-204).—Descriptive notes are given of a large number of tropical and semitropical fruits suitable for culture in Paraguay.

Wild fruits of Paraguay, G. T. BERTONI (*Agronomia [Puerto Bertoni]*, 5 (1913), No. 5-6, pp. 205-207).—The author enumerates a number of wild fruits belonging to the genera *Psidium*, *Eugenia*, *Rollinia*, and *Anona*, with special reference to their value for cultivation.

The pubescent-fruited species of *Prunus* of the Southwestern States, S. C. MASON (*U. S. Dept. Agr., Jour. Agr. Research*, 1 (1913), No. 2, pp. 147-178, pls. 8, figs. 8).—The author here describes seven species of *Prunus* found in the flora of the western United States which are more closely allied to some of the Asiatic species of this genus than to the wild plums of the country. They are discussed with special reference to their adaptation as stocks for cultivated forms under the climatic and soil conditions of the Southwest, and also as offering possibilities to the plant breeder.

The species discussed include the Texas wild peach (*P. texana*) and hybrid forms, the Nevada wild almond (*P. andersonii*), the desert apricot (*P. eriogyna* n. sp.), the California desert almond (*P. fasciculata*), the Texas almond (*P. minutiflora*), the Mexican almond (*P. microphylla*), and Havard's almond (*P. havardii*).

Fruit variety tests on the Southern Utah Experiment Farm, A. B. BALLANTYNE (*Utah Sta. Bul.* 124, pp. 59-110, pl. 1, figs. 3).—In continuation of a previous report (*E. S. R.*, 18, p. 936) this bulletin reports the condition up to 1910 of various orchard fruits, nuts, and grapes under test on the experimental farm.

Summarizing the results as a whole the test indicates that one may safely plant Elberta and Heath Cling peaches, most of the prunes, and at least the Bartlett pear on any soil in southern Utah that is at all adapted to fruit culture. Unusual care must be exercised in the selection of orchard sites, however, with special reference to spring frosts and soil drainage in order to avoid the consequent loss of fruit and early death of the trees. Tests conducted with various nuts indicate that, with the possible exception of pecans, nut culture is not promising for southern Utah. Generally speaking, the standard American grapes of the northern sections do not thrive. *Labrusca-Vinifera* hybrids, such as *Isabella*, *Agawam*, and *Goethe*, do well and the section appears to be adapted for many varieties of European grapes including fresh, raisin, and wine grapes.

Orchard notes, J. B. THOMPSON (*Guam Sta. Rpt.* 1912, pp. 24-26, pl. 1).—A brief statement of work accomplished in the introduction and establishment of various fruits in Guam, including the mango, peach, kumquat, amatungula (*Carissa arduina*), and the banana.

Fruit for exhibition, L. D. BATCHELOR (*Utah Sta. Circ.* 13, pp. 9-11).—In this circular the author briefly discusses the selection, storing, and arrangement of exhibition fruit, and presents a score card showing the important points for consideration in show fruit.

Box packing of apples, E. F. PALMER (*Ontario Dept. Agr. Bul.* 216, 1913, pp. 24, figs. 23).—Popular directions are given for making various styles of packs in boxes, including plans for packing houses and the necessary equipment.

Packing Indiana apples, W. R. PALMER (*Indiana Sta. Circ.* 39, pp. 28, figs. 15).—This circular discusses the equipment needed and the methods used in sizing, grading, and packing both barrels and boxes. Recent legislation pertaining to the subject is noted in the appendix.

Cold storage for Iowa-grown apples, L. GREENE (*Iowa Sta. Bul.* 144, pp. 357-378, figs. 2).—In continuation of a previous investigation (*E. S. R.*, 22, p.

142) the results of cold storage studies with apples conducted during the past 4 years are here reported.

A number of experiments were made to determine the effect of freezing the apples previous to storage upon their keeping quality in cold storage. It was found that apples which are frozen upon the trees in the fall can be safely placed in cold storage if they are still sound after having thawed out gradually on the tree before picking. Apples which are frozen in cold or in common storage will not be seriously injured if thawed out below freezing temperature.

A number of tests were made of cellar as compared with cold storage. As a result of these tests it would seem that where cold storage can be had close at hand it would be economical to store fruit for one or two months at a monthly rate until the cellar storage could be cooled to proper temperatures and then the fruit removed to the cellar. Cellar storage throughout the season in comparison with cold storage kept such varieties as Winesap and Mammoth Black Twig until May 1 in excellent condition, whereas such varieties as Grimes Golden and Jonathan in cellar storage should be marketed before January 1. By the use of early cold storage previous to cellar storage the season for Grimes Golden was prolonged to February 1.

In order to keep well in cold storage the fruit should be thoroughly ripened, well colored, and carefully handled. If the fruit has not been properly ripened delaying the storage after packing for a short time may prove beneficial, providing the weather remains cool. Wrapping the fruit with paper retards the ripening process, prevents bruising in shipment, and delays the appearance of scald, thus lengthening the storage season from 2 weeks to several months according to variety. From an economic standpoint, however, wrappers are out of the question, except for fancy boxed apples or where packed for special purpose in barrels. Other conditions being equal, the package in which the apples are stored has but little influence on their keeping qualities.

But little difference was found in the keeping qualities of fruit from cultivated and from sod orchards. Fruit selected for the extreme storage limit should be of medium size for the variety, since overgrown specimens do not keep as well as the smaller ones. Apple scald was found to attack immature, poorly colored fruit first. If the temperature is high enough to allow the fruit to continue the ripening processes the appearance of scald is somewhat delayed.

The cold storage variety testing was continued during the past 4 years. The results as here noted indicate that the principal commercial varieties in Iowa can nearly all be handled profitably in cold storage.

The American peach orchard, F. A. WAUGH (*New York and London, 1913, pp. 238, pl. 1, figs. 65*).—A treatise on the practice of peach growing in North America at the beginning of the twentieth century. The successive chapters of this work discuss peach growing geography, climatology, soils and exposures, how to get the trees, orchard planting, general management, cover crops, the use of fertilizers, pruning and renovation, insect enemies, diseases of tree and fruit, spraying, marketing the crop, the family orchard, botanical and pomological status, choosing varieties, variety catalogue, the nectarine, utilizing the fruit, and a historical sketch of the peach industry.

Maurer's gooseberry book, L. MAURER (*Maurer's Stachelbeerbuch. Stuttgart, 1913, pp. XIII+347, pls. 15, figs. 158*).—A descriptive account of the best and most widely cultivated varieties of gooseberries. Introductory considerations deal with the botany, anatomy, and culture of the gooseberry, weights and measurements of gooseberry fruits, methods of classification, and choice of varieties for general culture.

The practice of grape growing in its various phases.—I, The technique of grape grafting, A. WANNER (*Die Praxis des Weinbaus in Einzeldarstellungen. I, Die Technik der Rebenveredlung. Strassburg, 1913, pp. 83, figs. 53*).—A practical treatise on the propagation and grafting of grapes, including the care of the grafted plants in the nursery.

Study of the influence of various grape stocks on the quality and quantity of the harvest, H. FAES and F. PORCHET (*Terre Vaud., 5 (1913), Nos. 18, pp. 191-193, fig. 1; 19, pp. 204, 205, fig. 1; 20, pp. 211-213, figs. 2; 21, pp. 227-229, figs. 2; 22, pp. 245-247, figs. 2; 24, pp. 265-268, figs. 2; 26, pp. 285-288, figs. 3; 28, pp. 307-310, figs. 3; 31, pp. 335-338, figs. 4; 33, pp. 351, 352*).—In order to determine the adaptability of a number of pure American, American hybrid, and French-American hybrid stocks for the Chasselas grape 9 experimental vineyards were established under the direction of the Lausanne Viticultural Station. The results of this investigation as indicated by the quality and quantity of the harvest in 1911 and 1912 are here reported and discussed.

The sexual elements of grape hybrids, M. GARD (*Compt. Rend. Acad. Sci. [Paris], 157 (1913), No. 3, pp. 226-228*).—The author's investigations lead him to conclude that the deviations from normal in the sexual elements of grape hybrids are confined to the male flower, the female flower remaining normal. Among European cultivated grapes the pollen is oftentimes normal, and at other times normal, hollow-grained, and intermediate forms of pollen occur on the same plant, but the normal grains are usually the more numerous. Pollen from short stamens, although not infertile, is incapable of close fertilization.

Report on the variability of the coffees grown in the Dutch East Indies, P. J. S. CRAMER (*Meded. Dept. Landb. [Dutch East Indies], 1913, No. 11, pp. XVI+696, pls. 23, figs. 5*).—This comprises a comparative study of the varieties of coffee commonly grown in the Dutch East Indies, including also observations on recently introduced forms. Introductory considerations deal with the present status of coffee culture and varieties in Java, the introduction of new sorts for cultural tests, variability, comparative characteristics of different kinds of coffee, seed tests, and the methods followed in the descriptions of the parent trees.

Part 2 discusses in detail the varieties of *Coffea arabica*, including small-leaved, colored, erect, pendulous, and the strong-growing forms. The species discussed in the succeeding parts include *C. liberica*, *C. abeokutae*, *C. stenophylla*, *C. excelsa*, *C. ugandae*, and *C. congensis*.

First report on selection tests of Robusta coffee, C. J. J. VAN HALL (*Meded. Proefstat. Midden-Java, 1912, No. 7, pp. 23*).—With the view of securing an improved form of Robusta coffee, a large number of plants were studied with reference to variations in productivity, disease resistance, weight of marketable product as compared with yield, and quality of the berry. The results of this test are here presented in tabular form and discussed.

On the tarring of pruning-wounds in tea plants, C. BERNARD and J. J. B. DEUSS (*Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Proefstat. Thee, 1913, No. 25, pp. 1-8*).—In a preliminary test of various tar preparations, black gas house tar gave the most satisfactory results as a dressing for wounds resulting from pruning tea plants.

Tea manuring experiments, C. BERNARD and J. J. B. DEUSS (*Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Proefstat. Thee, 1913, No. 25, pp. 9-26, figs. 7*).—Some fertilizer investigations with tea in Java are here reported and discussed.

Leucæna glauca as a green manure for tea, C. BERNARD (*Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Proefstat. Thee, 1913, No. 25, pp.*

27-30, pls. 3).—Favorable results in the use of *L. glauca* as a green manure crop for tea plantations are here reported.

Individual variation in the alkaloidal content of belladonna plants, A. F. SIEVERS (*U. S. Dept. Agr., Jour. Agr. Research*, 1 (1913), No. 2, pp. 129-146, fig. 1).—The author has started an investigation to determine the possibility of modifying the chemical constituent of a plant by breeding and selection. This paper presents the results of three years' observations relative to the variation of the quantity of alkaloids in the belladonna plant as studied at the drug-testing garden at Bell, Md., and at the Arlington Experimental Farm.

Summarizing the work as a whole it was found that the variation of the percentage of alkaloids in the leaves of the different plants is exceedingly large, hence the testing of a general sample from all plants collectively is not always a safe means of judgment. A considerable number of plants with leaves rich in alkaloids in one season were found to have equally rich leaves in the following season, and they frequently manifested the same characteristics at the various stages of growth during the season in comparison with other plants. The same facts were true with regard to plants which bear leaves with a low percentage of alkaloids. Thus far, however, nothing has been found to indicate that any correlation exists between the physical appearance of the plant and the alkaloidal content of its leaves, luxuriant growth being no criterion of the medicinal value of the plant.

From the point of view of the percentage of alkaloids present in the leaves and the quantity of material available, the leaves can be picked to best advantage from the time of flowering until the early berries begin to ripen. They are richer in alkaloids later in the season but are then too small and sparse for harvesting.

Rose geranium culture, E. CHARABOT and C. L. GATIN (*Jour. Agr. Trop.*, 13 (1913), No. 148, pp. 289-295).—A descriptive account in which consideration is given to the origin of rose geranium culture in France, Algeria, and Réunion, methods of propagation, cultural details, enemies and diseases, harvesting, distillation and yields, and the present and future status of the industry.

FORESTRY.

Forestry, H. HAUSRATH (*Die Waldwirtschaft. In Das Leben der Pflanze, Abt. IV: Die Pflanzen und der Mensch, Vol. I. Stuttgart, 1913, pp. 471-611, pls. 4, figs. 70*).—An encyclopedic treatise in which consideration is given to the history of forestry, forest management, forest protection, forest statistics, beneficial effects of woods, and ornamental value of woodlands.

Forestry, A. KOSTLAN (*Jahresber. Landw.*, 27 (1912), pp. 215-228).—A review of recent contributions to forest literature in Germany.

Logging, R. C. BRYANT (*New York and London, 1913, pp. XVIII+590, figs. 133*).—A text-book on the principles and general methods of operation in the United States. Part 1 contains a general discussion of forest resources, protection of forest property, and timber bonds. The succeeding parts take up in detail the methods of preparing logs for transport, land transport, water transport, summary of logging methods in specific regions, and minor industries.

A bibliography together with terms used in logging (E. S. R., 17, p. 373), log rules, and other data relating to the industry are appended.

Work of the Dominion Forestry Branch, R. H. CAMPBELL (*Com. Conserv. Canada Rpt.*, 4 (1913), pp. 32-40).—A review of the work of the Dominion Forestry Branch, presented at the fourth annual meeting of the Commission of Conservation of Canada, Ottawa, January 21-22, 1913.

[Report of the] committee on forests, C. LEAVITT ET AL. (*Com. Conserv. Canada Rpt.*, 4 (1913), pp. 16-31, 178-180, pls. 3).—This comprises the report of the forestry committee of the Commission of Conservation of Canada for the fiscal year ended March 31, 1913, including also the resolutions pertaining to forestry that were adopted by the commission.

Forest policy of British Columbia, W. R. ROSS ([*Victoria*], 1913, pp. 17).—This is a full report of the author's speech in which he reviews the progress that forest conservation has made in British Columbia.

Avondale Forestry Station, A. C. FORBES (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 14 (1913), No. 1, pp. 102-125, pls. 6).—This comprises a general description of the Avondale Forestry Station, including a progress report of the work for the period 1906 to 1912.

Report on forest statistics of Alsace-Lorraine (*Bcitr. Forststatist. Elsass-Lothringen*, 1911, No. 30, pp. 100, figs. 17).—This is the customary statistical review, for the year 1911, relative to the administration of the state, public, and community forests in Alsace-Lorraine. Detailed and summarized data dealing with forest areas, silvicultural operations, products, revenues, expenditures, etc., are given, including a comparative summary for each year since 1872.

The sun energy in the forest, M. WAGNER (*Allg. Forst. u. Jagd Ztg.*, 89 (1913), June, pp. 185-200; July, pp. 225-242, fig. 1; Sept., pp. 297-316, fig. 1; Oct., pp. 333-351, fig. 1).—A study of the relation of the sun's energy to forest growth, in which the author sets forth his observations and deductions in a series of articles as follows: (1) The Influence of Geographic Latitude on Crown Development, Volume Production, Stem Basal Area, Stem Number, and Brush Wood; (2) The Distribution of the Sun's Rays in the Forest, with Special Reference to the Selection Strip Cutting; (3) The Absorption of Sun Energy in Green Plant Leaves and Its Relation to the Locality and to Volume Production; and (4) Light Measurements in the Forest and Their Importance for Practical Forestry.

Contribution to the knowledge of the influence of aquatic mediums on the roots of trees, G. BONDOIS (*Ann. Sci. Nat. Bot.*, 9. ser., 18 (1913), No. 1-2, pp. 1-24, figs. 9).—The author's investigations as here reported lead him to conclude in general that although the adaptation of tree roots to aquatic mediums may be less marked than their adaptation to aerial mediums it is nevertheless quite appreciable. The roots appear to be influenced by both the physical and chemical nature of the water. Since water is a homogeneous medium the root growth is equal and symmetrical in all directions. On account of its density the water acts as a partial support to the roots, whence arises a reduction in the supporting system. In order to adapt themselves for floating the roots lighten themselves by the development of air cells. Since the food supplied to the roots is liquid the absorption and conducting systems become reduced. Since the absorption takes place throughout the emerged surface a great abundance of lenticels are formed on the older roots.

Florida trees, J. K. SMALL (*New York*, 1913, pp. IX+107).—This handbook contains descriptions of all the trees known to the author to be native to or to grow naturally in Florida.

The forests of the Far East, A. HOFMANN (*Aus den Waldungen des fernen Ostens. Vienna and Leipsic*, 1913, pp. VIII+225, pls. 56, figs. 9).—A descriptive account of the forests and of forestry in the Far East, based upon the author's travels and studies in Japan, Formosa, Korea, and the bordering districts of eastern Asia, together with a review of the literature on the subject.

Introductory considerations deal with the geology, climate, and forest geography of the region under discussion. The succeeding chapters deal with the silvicultural practices; ownership and management relations; utilization; timber sales; wood industries and trade; strength investigations; transportation; forest policies, laws, and administration; the relation between the forests and streams; game and hunting; and the national attitude toward the forests.

Some Douglas fir plantations.—II, Cochwillan wood, near Llandegai, North Wales, T. THOMSON (*Jour. Bd. Agr. [London]*, 20 (1913), No. 6, pp. 499–503).—In continuation of previous observations on Douglas fir plantations (E. S. R., 29, p. 644) some diameter, height, and volume measurements are given for a 58-year-old Douglas fir stand growing in a mixture with oak, near Llandegai, North Wales.

The structure of the wood of East Indian species of *Pinus*, P. GROOM and W. RUSHTON (*Jour. Linn. Soc. [London] Bot.*, 41 (1913), No. 283, pp. 457–490, pls. 2).—In the first part of this paper the authors give their general conclusions and summarize the results secured from a detailed study of the wood structure of 5 species of East Indian pine. The second part of the paper describes in detail the wood structure of the different species.

The kapok trees of Togo, E. ULBRICH (*Notizbl. K. Bot. Gart. u. Mus. Berlin*, 6 (1913), No. 52, pp. 39–65, figs. 2).—This comprises the results of inquiries sent out to the various districts of Togo relative to the characteristics and varying forms of the kapok trees.

The “wood-oil” trees of China and Japan, E. H. WILSON (*Bul. Imp. Inst. [So. Kensington]*, 11 (1913), No. 3, pp. 441–461, pls. 5).—The author here gives a descriptive account of the Chinese wood oils and the trees yielding them, with special reference to the utilization of these facts by various departments of agriculture in the warm temperate and subtropical parts of the world which contemplate the experimental culture of these trees. A revision of the synonymy with principal references to the literature is appended.

Tagua, vegetable ivory, E. ALBES (*Bul. Pan Amer. Union*, 37 (1913), No. 2, pp. 192–208, figs. 21).—A descriptive account is given of the tagua palm (*Phytelphas macrocarpa*) with reference to its botany and habitat, methods of harvesting and marketing the tagua nuts, and their utilization in the manufacture of vegetable ivory buttons.

Uses of commercial woods of the United States.—Beech, birches, and maples, H. MAXWELL (*U. S. Dept. Agr. Bul.* 12, pp. 56).—In continuation of previous studies of the commercial woods of the United States (E. S. R., 26, p. 50) consideration is here given to the closely related beech, birch, and maple group, including some 18 commercial species, with special reference to the physical properties, supply, and uses of the various woods.

The wood-using industries of Iowa, H. MAXWELL and J. T. HARRIS (*Iowa Sta. Bul.* 142, pp. 237–304, figs. 13).—This report embraces the results of an investigation conducted cooperatively by the Forest Service of the U. S. Department of Agriculture and the Iowa Station relative to the utilization by various industries in Iowa of wood after it has left the sawmill. The data presented and discussed show the total demands for each species by the different industries; cost of the raw material f. o. b. factory; the articles made from each kind of wood; the relative amounts supplied by the State and by outside States; and the qualities of the wood which recommend it for a specific use.

A directory of Iowa wood users is given and the following special chapters are also included: The Timber Resources of Iowa, by G. B. MacDonald (pp. 291–300); and White Pine in Iowa, by N. C. Brown (pp. 301–304).

Forest products of Canada, 1912.—Lumber, square timber, lath, and shingles, R. G. LEWIS and W. G. H. BOYCE (*Dept. Int. Canada, Forestry Branch*

Bul. 40, 1913, pp. 67, pl. 1).—A statistical report on the manufacture of lumber, square timber, lath, and shingles in the Dominion and the various Provinces for the calendar year 1912. The production is also indicated by species.

The total value of lumber, square timber, lath, and shingles produced in Canada in 1912 was \$76,540,879, of which amount the lumber represents about \$69,500,000.

To get long life from untreated timber in trestles (*Engin. Rec.*, 68 (1913), No. 20, p. 542).—This comprises suggestions made by the committee on the preservation of timber of the American Railway Bridge and Building Association relative to methods of prolonging the life of overhead timber and piles used in trestle work which receive no preservative treatment. A table is also given showing the relative length of life of various structural timbers in contact with the soil and in the air.

DISEASES OF PLANTS.

Smut diseases of cultivated plants, their cause and control, H. T. GÜSSOW (*Canada Cent. Expt. Farm Bul.* 73, pp. 57, figs. 9).—After a general discussion of smuts as related to plants, the author describes the smuts of wheat, barley, oats, corn, broom corn, and millet, giving methods for their control, as far as definite recommendations can be made.

Further cultures of heteroecious rusts, W. P. FRASER (*Mycologia*, 5 (1913), No. 4, pp. 233-239).—The author adds to studies previously reported (*E. S. R.*, 28, p. 51) an account of 5 rusts of the genus *Uredinopsis* whose life histories are claimed to be established for the first time; and, in addition, 3 life histories supplementing previous work.

Some important contributions on fungus diseases of plants appearing in 1912-13, E. RIEHM (*Mycol. Centbl.*, 3 (1913), No. 2, pp. 66-76).—Brief notes are given of studies on plant diseases in 1912-13, concluding with a list of about 80 articles representing about 70 different contributors.

Diseases of agricultural crops, 1912, J. LIND, SOFIE ROSTRUP, and F. K. RAVN (*Tidsskr. Landbr. Planteavl*, 20 (1913), No. 2, pp. 249-280).—The more important plant diseases and insect pests observed in Denmark during the year are described and discussed.

Work of the phytopathological section of the central agricultural experiment station in Stockholm in 1912, J. ERIKSSON (*Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 7, pp. 1005-1008).—A condensed account is given of observations carried out on potato diseases, including *Phytophthora infestans*, *Hypochnus solani* or *Rhizoctonia solani*, and *Chrysophlyctis endobiotica* or *Synchytrium solani*; on beet diseases, including *Uromyces betæ*, *Bacillus tabificans*, *R. violacea*, *Phoma betæ*, *Cercospora beticola*, *Sporidesmium putrefaciens*, etc.; on withering of blooms on fruit trees; and on various diseases of vegetables. A list of the station publications appearing in 1912 is also given.

Work of the observatory of phytopathology in Turin, P. VOGLINO (*Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 7, pp. 1000-1005).—This is a brief account of the organization of this institution, and of parasitic fungi, etc., studied there, by years from 1904 to 1912.

Plant diseases, E. W. DAVY (*Nyasaland Dept. Agr. Ann. Rpt.* 1913, pp. 23, 24).—Brief notes are given on the occurrence of frog-eye of tobacco due to *Cercospora nicotianæ*, the attack of safflower by a species of *Vermicularia*, a disease of Ceara rubber tree due to some species of *Polyporaceæ* as yet undetermined, and the orange scab caused by *Cladosporium citri*. The presence of

peculiar wart-like excrescences on the leaves of oranges is reported from Central Angoniland, but so far no fungus or other growth has been found associated with this trouble. A blackening and dying of the shoots of young camphor trees is reported, due to some indeterminate cause, as is also a spasmodic disease of tea, in which a shot hole effect is produced on the leaves.

Some fungi parasitic on tropical plants, E. GRIFFON and A. MAUBLANC (*Bul. Trimest. Soc. Mycol. France*, 29 (1913), No. 2, pp. 244-250, pl. 1, figs. 2; *abs. in Internat. Inst. Agr. [Rome]*, Mo. *Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 7, pp. 1120, 1121).—The authors report as the result of their study of material sent from the mouth of the Amazon that *Dothidella ulei* in its various forms is found living parasitically on leaves of *Hevea brasiliensis*. It seems to be harmless under normal conditions although nursery plants, as in case of some examined, may suffer considerably from its presence.

On leaves of *Butyrospermum parkii* from near Kulikoro (Upper Senegal and Niger), were found 2 fungi considered to be new and described under the names of *Fusicladium butyrospermi* and *Pestalozzia heterospora*.

Handbook of fungus diseases of the potato in Australia and their treatment, D. MCALPINE (Melbourne: Dept. Agr. Victoria, 1912, pp. III+215, figs. 158, map 1; rev. in *Nature [London]*, 92 (1913), No. 2289, p. 27).—In this book the author gives detailed accounts of the diseases of the potato, particularly those caused by *Phytophthora infestans*, *Alternaria solani*, *Rhizoctonia* sp., *Fusarium solani*, *Bacillus solanacearum*, and the diseases known as scab.

Bacterial disease of potatoes, T. G. B. OSBORN (*Jour. Dept. Agr. So. Aust.*, 17 (1913), No. 1, pp. 19-21, fig. 1).—Specimens of potatoes attacked by the bacterial rot (*Bacillus solanacearum*) were submitted to the author for study, and it seems that this disease has become established in South Australia. The disease occurs also in Victoria, where it is popularly known as sore eyes, from the moist condition of the buds in the early stages of the rot.

Suggestions are given for the control of the disease, which include the removal and burning of infected plants, the use of clean seed tubers, and the rotation of crops.

Report of the committee for study of leaf roll.—VII, Biology of the potato plant with particular reference to leaf roll, O. REITMAIER (*Ztschr. Landw. Versuchsw. Österr.*, 16 (1913), No. 6, pp. 653-717).—Besides a discussion of statements by other investigators, the author gives in continuance of previous reports (*E. S. R.*, 27, p. 447) the results obtained in a series of recent investigations. He states in conclusion that while leaf roll is a relative term rendering reports by various observers uncertain or conflicting in cases not very marked, it may be stated with a degree of certainty that instances of transitory leaf roll or of recovery in well established cases have not been seen by him; that this trouble normally shows itself relatively late in the development of the potato plant, usually near the middle of June, when individuals which have inherited this trouble in typical degree show along with precocious blooming a development of storing organs and marked setback in growth of the plant, especially as regards the root system; that as soon as the other signs of leaf roll appear, a disturbance or checking of the transportation of elaborated materials from the leaves is observable with alterations of phloem, concerning which further study is regarded as desirable; and that considerable variations are observable as regards the degree of susceptibility of different varieties of potatoes to this trouble.

The recent researches of Quanjer as to the cause of potato leaf roll and Sorauer's standpoint, P. SORAUER (*Ztschr. Pflanzenkrank.*, 23 (1913), No. 4, pp. 244-253).—A critical discussion of an article previously noted (*E. S. R.*,

29, p. 347), citing also views of other investigators regarding leaf roll of potatoes.

The persistence of the potato late blight fungus in the soil, F. C. STEWART (*New York State Sta. Bul.* 367, pp. 357-361).—On account of conflicting statements regarding the persistence of the fungus *Phytophthora infestans* in the soil and the discovery of the oospores of the potato blight (E. S. R., 25, p. 545), the author carried on experiments in soil from a field in which a large portion of the potato crop had been destroyed by the *Phytophthora* rot. The soil together with a quantity of blighted potato stems was placed in wooden boxes, which were left in the field until late in January when they were brought into the greenhouse and planted to potatoes. A second experiment, which was practically a repetition of the first with some modifications, was conducted, but the results were negative in each case.

The conclusion is reached that while the negative results do not prove that the *Phytophthora* does not persist in the soil, they make such persistence appear highly improbable, and the removal of diseased tubers from the field, as recommended by Massee (E. S. R., 17, p. 45), is considered unnecessary. While the planting of potatoes after potatoes is said to have a tendency to increase scab, wilt, and other diseases, it is believed that there is no risk in the practice so far as the late blight or rot is concerned.

Does winter kill potato blight in the soil? F. H. HALL (*New York State Sta. Bul.* 367, popular ed., p. 1).—This is a popular edition of the above.

Potato spraying experiments in 1911, N. J. GIDDINGS (*West Virginia Sta. Rpt.* 1912, pp. 77, 78).—An account is given of experiments conducted at Moundsville, W. Va., during 1911 with the object of determining the relative value of Bordeaux mixture when prepared by various methods of mixing or by using formulas other than those commonly employed. Atomic sulphur was also tested as a spray for potatoes.

The weather during the early part of the season was exceedingly dry and hot, and many of the plants were destroyed. The results as to spray mixtures are not considered of any special value, as it was impossible to get the potatoes sprayed at a time when they were most seriously in need of it.

Ufra disease of rice, E. J. BUTLER (*Agr. Jour. India*, 8 (1913), No. 3, pp. 205-220, pl. 1, fig. 1).—In continuation of a preliminary note (E. S. R., 28, p. 151), a detailed account is given of a study of this rice disease in India.

Two distinct manifestations of the disease are described, and it has been definitely determined that it is due to *Tylenchus* sp. The occurrence of this disease has been known for a number of years, but only recently has it become very destructive, losses of from 10 per cent to total destruction of fields having been reported.

The different crops of rice are said to be affected in unlike manner, and transplanted rice seems practically free from attack. A lack of aeration of the soil is thought to favor the attack of the nematodes, but other considerations, among them the accumulation of nitrites, must be taken into account in plans for the control of this disease. A special grant has been made in Bengal for extensive experiments on means for its control.

Notes on sereh disease of sugar cane, S. F. ASHBY (*Bul. Dept. Agr. Jamaica, n. ser.*, 2 (1913), No. 7, pp. 239, 240, pl. 1).—On account of the suspected occurrence of the sereh disease of sugar cane in Trinidad, the author gives a description of the external and internal appearances of diseased cane. Two views are held regarding the cause of this disease, one that it is due to a gum-forming bacterium, and the other that it is caused by a lack of balance in enzym action within the living cells of the plant, brought about by abnormal conditions of the soil, cultivation, manuring, etc.

Rangpur tobacco wilt, C. M. HUTCHINSON (*Mem. Dept. Agr. India, Bact. Ser., 1 (1913), No. 2, pp. 67-84, pls. 12*).—The wilting of tobacco plants, due to infection with a bacterium similar to *Bacillus solanacearum*, is said to occur annually in the Rangpur district of Bengal. It is thought that the infecting organism is probably unable to gain entrance into the plant except through the intervention of some mechanical injury or of organisms such as nematodes, which bore into the roots of the plant.

For the control of the disease attempts should be made to conserve the soil moisture and develop the root system so as to produce a better and more rapid growth. All diseased plants should be removed and burned, and the use of alkaline manures should be avoided as much as possible.

Diseases of the tomato in Louisiana, C. W. EDGERTON and C. C. MORELAND (*Louisiana Stas. Bul. 142, pp. 23, figs. 3*).—There are said to be ten diseases of tomatoes known in Louisiana as follows: Tomato wilt (*Fusarium lycopersici*), early blight (*Alternaria solani*), Sclerotium wilt disease (*S. rolfsii*), root knot (*Heterodera radiculicola*), blossom end rot, leaf mold (*Cladosporium fulvum*), anthracnose (*Glæosporium fructigenum*), southern tomato blight (*Bacterium solanacearum*), leaf curl, and damping off (*Rhizoctonia* sp.). These diseases are described at some length and means are suggested for their prevention, as far as any are known.

In connection with the wilt the author states that some wilt resistant varieties have been developed at the station at Baton Rouge, and seed of these is to be distributed for further trial in the State.

Apple leaf spot (*Jour. Bd. Agr. [London], 20 (1913), No. 6, pp. 513-515, pl. 1*).—A description is given of the apple leaf spot due to *Sphæropsis malorum*, which, it is said, has only recently been reported in Great Britain, although in all probability it has been present for a considerable time and has been overlooked or confused with other diseases.

Peach leaf curl fungus: Further tests with copper compounds, G. QUINN (*Jour. Dept. Agr. So. Aust., 17 (1913), No. 1, pp. 28-32*).—In 1910 a series of spraying tests for the control of the peach leaf curl fungus (*Exoascus deformans*) was reported (E. S. R., 26, p. 144). In 1911 the treatment as planned was not carried out, but it was repeated in 1912, and an account is given of the results. The spraying compounds used were Bordeaux mixture, Burgundy mixture, Woburn Bordeaux mixture, copper sulphate solution, and Bordeaux powder.

As a result of the two seasons' trials, Burgundy mixture is deemed well adapted to the control of the peach leaf curl. When applied twice during the season ordinary Bordeaux mixture was very efficient, and a single season's trial has given similar results with the Woburn Bordeaux mixture. Copper sulphate solution, while giving good results in 1910, proved almost a failure in 1912, so far as the control of the disease was concerned. The Bordeaux powder seems to be promising, but the results of 1 and 2 applications are said to be contradictory.

Comparative experiments with sprays against leaf cast of grape, A. BRETSCHNEIDER (*Ztschr. Landw. Versuchsw. Österr., 16 (1913), No. 6, pp. 718-725*).—Giving the results of recent experiments with means of combating *Peronospora viticola*, the author sums up the results of his studies during about four years (E. S. R., 27, p. 652) by stating that besides Bordeaux mixture some commercial preparations have been found entirely satisfactory and a few others named measurably so, while still others mentioned as on trial seem to promise good results.

A disease of cacao trees due to *Lasiodiplodia theobromæ*, P. BERTHAULT (*Bul. Trimest. Soc. Mycol. France, 29 (1913), No. 3, pp. 359-361; Agron. Colon.,*

1 (1913), No. 1, pp. 8-14, pl. 1, figs. 3).—The author states that in Dahomey a disease of cacao trees is present which is commonly designated as sunstroke or apoplexy. The leaves on the trees often turn yellow, dry, and fall without the trees showing any pronounced indication of disease. The trouble seems most prevalent during the dry season, and in certain regions three-fourths of the plants have been attacked. A study of the leaves showed they were parasitized by a fungus which proved to be *L. theobromæ*. The synonymy of the fungus is given, from which it appears that it has been previously described under a number of names.

Nematode worms and mottled leaf, J. R. HODGES (*Mo. Bul. Com. Hort. Cal.*, 2 (1913), No. 6, pp. 555, 556).—An account of investigation and treatment of mottled leaf of citrus trees.

An examination of affected trees on different kinds of soil showed an imperfect condition in the fibrous root system common to all trees badly affected with mottled leaf. By scraping the rootlets while submerged in water, live, actively moving nematodes were found, in many cases these being very numerous on badly decayed roots. It is suggested that these often infest the roots of transplanted nursery stock and that they also spread from one tree to another in irrigation and storm water. It is said that some of these nematodes were kept for 8 days in water without apparent injury. In badly infested orchards they appear to attack also the roots of various weeds.

The author reports some success in treating affected trees with carbon bisulphid. The best results were obtained by making shallow holes about 2 in. deep, 1 ft. apart each way, and putting about three-fourths of an ounce of carbon bisulphid in each hole, the ground being then covered with an impervious tent or cloth which was allowed to remain for about 48 hours. After this treatment no live nematodes could be found. Just how much smaller dosage could be used with success is not known, but trees treated with greater amounts showed injury, losing their leaves. After treating, the ground was covered with a mulch of barnyard manure about 1 in. thick which kept up an even moisture content of about 10 per cent during the season following. The trees then showed a normal condition of fibrous roots, and while not entirely free from the nematodes, they are now reported as doing very well.

Two fungi as causal agents in gummosis of lemon trees in California, H. S. FAWCETT (*Mo. Bul. Com. Hort. Cal.*, 2 (1913), No. 8, pp. 601-617, figs. 12).—It is stated that at least two forms of gummosis occur in California that are readily transmissible by inoculation. One of these is due to the fungus *Botrytis vulgaris*, the other to the brown rot fungus (*Pythiacystis citrophthora*).

The *Botrytis* gummosis is characterized by the killing of the outer layer of the bark much in advance of the inner, and by a softening of the bark and the production of spores in moist weather, where the bark is entirely killed to the wood. The brown rot gummosis is characterized by the killing of the bark to the wood as the area of infection advances, without outward evidence of the fungus at any time.

The use of concentrated Bordeaux mixture or Bordeaux paste has given promising results in the treatment of these forms of gummosis if the diseased areas were properly prepared before their application.

Two fungus parasites of *Agati grandiflora*, E. FOEX (*Bul. Trimest. Soc. Mycol. France*, 29 (1913), No. 3, pp. 348-352, figs. 3).—Descriptions are given of *Oidium agatidis* n. sp. and *Cercospora agutidis* n. sp., parasitic on *A. grandiflora*, an ornamental tree extensively grown in Cochin China.

The structure and systematic position of *Mapea radiata*, R. MAIRE (*Bul. Trimest. Soc. Mycol. France*, 29 (1913), No. 3, pp. 335-338, fig. 1).—In 1906

there was described by Patouillard as new, under the name *M. radiata*, a parasite of the pods of the leguminous tree *Inocarpus edulis*, and at that time it was considered as belonging to the Uredineæ. Other investigators have since claimed that it is only a young form of *Marasmius hygrometricus*.

The author of the present paper reports a cytological study of the fungus. He has grown it on culture media and as the result of inoculation experiments proved it to be a parasite on *Inocarpus* pods. He agrees with Patouillard that the fungus belongs to the Uredineæ and is probably a reduced form of *Uredo*.

A new species of *Endothia*, L. PETRI (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 22 (1913), I, No. 9, pp. 653-658, figs. 2; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 7, pp. 1121, 1122).—The author describes under the name *E. pseudoradicis* a fungus, supposedly new, found near the bases of chestnuts 5 or 6 years old sprung from stumps of trees cut on account of black canker. The *Endothia* is said to show in one direction characters resembling *E. virginiana* and in another those resembling *E. parasitica*.

More on black canker of chestnut in reply to L. Petri, G. BRIOSI and R. FARNETI (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 22 (1913), II, No. 2, pp. 49-52).—A controversial note, referring also to a report by Ducomet (*E. S. R.*, 28, p. 240).

Critical considerations on black canker of chestnut, L. PETRI (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 22 (1913), I, No. 7, pp. 464-468).—A discussion of the foregoing article.

Three undescribed heart rots of hardwood trees, especially of oak, W. H. LONG (*U. S. Dept. Agr., Jour. Agr. Research*, 1 (1913), No. 2, pp. 109-128, pls. 2).—In connection with a study of oak trees in the Ozark National Forest, Arkansas, the author recognized at least 20 different kinds of heart rots, some of which appear to have been undescribed. In the present paper detailed descriptions are given of a pocketed or piped rot of the oak, chestnut, and chinquapin, caused by *Polyporus pilotæ*, a string and ray rot of the oak caused by *P. berkeleyi*, and a straw colored rot caused by *P. frondosus*.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Principles of economic zoology, L. S. and M. C. DAUGHERTY (*Philadelphia and London*, 1912, pp. VII+410, figs. 301).—This work combines the salient facts as to the structure, life history, and habits of animals.

Game laws for 1913, T. S. PALMER, W. F. BANCROFT, and F. L. EARNshaw (*U. S. Dept. Agr. Bul.* 22, pp. 59).—This, the fourteenth annual summary of the game laws of the United States and Canada, has been prepared on the same general plan as those previously issued (*E. S. R.*, 28, p. 853).

Bibliography of Canadian zoology for 1911, L. M. LAMBE (*Proc. and Trans. Roy. Soc. Canada*, 3. ser., 6 (1912), Sect. IV, pp. 101-114).—This annotated list covers the literature exclusive of entomology.

Bibliography of Canadian entomology for 1911, C. G. HEWITT (*Proc. and Trans. Roy. Soc. Canada*, 3. ser., 6 (1912), Sect. IV, pp. 115-127).—One hundred and sixteen titles are listed in this annotated bibliography.

Forty-third annual report of the Entomological Society of Ontario, 1912 (*Ann. Rpt. Ent. Soc. Ontario*, 43 (1912), pp. 143, pl. 1, figs. 42).—Among the more important papers here presented are the following: The Faunal Zones of Canada, by E. M. Walker (pp. 27-33); Review of Entomology Relating to Canada in 1912, by C. G. Hewitt (pp. 34-37); The Chinch Bug in Ontario, by H. F. Hudson (pp. 46-50); Bumblebees and Their Ways, by F. W. L. Sladen

(pp. 50-56); Progress of the Introduction of the Insect Enemies of the Brown-tail Moth, *Euproctis chrysorrhæa*, into New Brunswick and Some Biological Notes on the Host, by J. D. Tothill (pp. 57-61); San José Scale in Nova Scotia, by G. E. Sanders (pp. 61-66); Recent Work on the Apple Maggot in Ontario, by W. A. Ross (pp. 67-72); Insects of the Season in Ontario, by L. Caesar (pp. 75-84); Insect Pests of Southern Manitoba During 1912, by N. Criddle (pp. 97-100); Some New or Unrecorded Ontario Insect Pests, by L. Caesar (pp. 100-105); Notes on Injurious Insects in British Columbia in 1912, by R. C. Treherne (pp. 106-111); and Arsenite of Zinc as a Substitute for Arsenate of Lead, by L. Caesar (pp. 111, 112).

Insects of the year in British Columbia, T. CUNNINGHAM (*Proc. Brit. Columbia Ent. Soc., n. ser., 1911, No. 1, pp. 15-22*).—Brief accounts are given of the occurrence of the more important insect pests in British Columbia during 1911.

Some new and unusual insect attacks on fruit trees and bushes in 1912, F. V. THEOBALD (*Jour. Bd. Agr. [London], 20 (1913), No. 2, pp. 106-116, pl. 1*).—Among some of the more important insects noted are the apple leaf sawfly (*Lygæonematus mæstus*); the beech Orchestes (*Orchestes fagi*), which seriously injured apples; the garden chafer (*Phyllopertha horticola*), observed to attack apples in its adult stage; the V moth (*Halia wavarra*) on currants and gooseberries; the pear leaf curling midge (*Cecidomyia pyri*); the red bug *Atractonotus mali* attacking apples; the ash and willow scale (*Chionaspis salicis*) attacking currants; the sycamore coccus (*Pseudococcus aceris*) attacking apple trees; the delicate strawberry aphid (*Myzus fragariae*); the northern currant aphid (*Rhopalosiphum brittenii*); the dark green Ribes aphid (*Aphis grossulariae*); and a phytoptid attacking apple leaves.

Report on economic zoology for the year ending September 30, 1912, F. V. THEOBALD (*Jour. Southeast. Agr. Col. Wye, 1912, No. 21, pp. 111-221, pls. 17, figs. 33*).—This is the author's annual report (E. S. R., 28, p. 248) on the more important insect pests of the year, which are taken up under the headings of animals injurious to fruit trees and bushes, hops, cereals, pulse, root crops, vegetables, flowers, and forest trees, those causing annoyance to man, and those injurious to furniture, stored food, etc.

A sealed paper carton to protect cereals from insect attack, W. B. PARKER (*U. S. Dept. Agr. Bul. 15, pp. 8, figs. 8*).—This bulletin, based upon observations and experiments made in California, has been summarized by the author as follows:

"Cereals may become infested before they are packed, after the packages are placed in warehouses, and in the grocery stores. Insects find their way in at the small holes which are usually present at the corners of unsealed packages or at holes accidentally punched in the sides. Thorough sterilization at 180° F. kills all insect life; and if the cereal is run from the sterilizer either through a sterile cooler or directly into sterile packages and immediately sealed, it will not become infested unless the package is broken. Sterilization of the knocked-down cartons before packing and cleanliness with regard to the exclusion of insects from the packing room will greatly facilitate the preparation of sterile packages and is strongly recommended. It is absolutely necessary that all machinery connecting the sterilizer and the packages be free from insects. If the cereal is passed through chutes or conveyors which can not be sterilized or are not kept sterile, it will, through these sources, become infested even though the cereal was previously sterile and was packed in sterile packages."

Spontaneous septicemia in the cockchafer and the silkworm due to coccobacilli, E. CHATTON (*Compt. Rend. Acad. Sci. [Paris], 156 (1913), No. 22, pp.*

1707-1709).—In investigations conducted in May, 1912, the author found *Coccobacillus acridiorum* to cause the death of cockchafer in from 24 to 48 hours when injected into the body cavity. When ingested, however, it does not affect the cockchafer.

The author also found a septicemia to be caused by a coccobacillus (*Bacillus melolonthæ*). This is much similar to *C. acridiorum*, but differs in a constant manner both in its morphological and cultural characteristics, including a somewhat greater length and the production of fluorescence in gelatin after cultivation for 5 or 6 days, and also by its pathogenic action on the silkworm. When injected into the body cavity an uncultivated virus killed the cockchafer in from 12 to 24 hours, but when ingested it is innocuous. *B. melolonthæ* was found in the digestive tract of 75 per cent of healthy cockchafers, in some cases in great numbers, as is always the case in septicemic specimens. Thus the septicemia appears to be of intestinal origin, as occurs in the locust. It was found that the silkworm possesses a complete natural immunity against *C. acridiorum*, while *B. melolonthæ* is as virulent in the silkworm as in the cockchafer when injected and as inactive when ingested.

Another coccobacillus (*B. bombycis*) proved to be the cause of a septicemia in the silkworm. During the rearing of some 2,000 worms from 5 to 10 individuals are said to have succumbed daily to this disease. In its morphology this bacillus resembles *B. melolonthæ*, but it does not form fluorescence in gelatin and is clearly differentiated from *C. acridiorum* by its greater virulence. Like *B. melolonthæ* it proves fatal to the silkworm in from 12 to 24 hours when injected into the body cavity. By ingestion the author infected 4 out of 27 individuals. Thus it is more virulent than either *B. melolonthæ* or *C. acridiorum*, but is much less widely distributed and abundant in the digestive tube of healthy silkworms than is *B. melolonthæ* in the cockchafer. See also a previous note (E. S. R., 29 p. 855).

In this disease of the silkworm, which has previously escaped recognition, no external symptoms are noticed before death. The coccobacillosis, as termed by the author, is essentially different from the well-known flacherie, grasserie, and polyhedral body disease.

The coccobacilli infections of insects, F. PICARD and G. R. BLANC (*Compt. Rend. Acad. Sci. [Paris]*, 157 (1913), No. 1, pp. 79-81; *abs. in Rev. Appl. Ent.*, 1 (1913), Ser. A, No. 9, pp. 336, 337).—In further investigations of its pathogenicity (E. S. R., 29, p. 855), *Coccobacillus caja* was found to cause the death of various Coleoptera, Hemiptera, Orthoptera, and Lepidoptera into which it was injected, including the cockchafer, brown-tail moth, silkworm, etc. During the course of examinations made of the gipsy moth, which was unusually abundant in southern France during the year, the authors discovered a coccobacillus, causing a fatal septicemia, which they name *Bacillus lymantriæ*. In investigations conducted it was found possible to kill *Aretia caja* caterpillars with a few drops of a culture of *C. caja* when introduced into the pharynx by means of a pipette without finding a trace of the organism in the blood. It is pointed out that *C. caja*, *B. bombycis*, *B. melolonthæ*, and *B. lymantriæ* differ from *C. acridiorum* in that the last-named is fatal to the locust when ingested but innocuous to the silkworm.

Locust bacterial disease, C. P. LOUNSBURY (*Agr. Jour. Union So. Africa*, 5 (1913), No. 4, pp. 607-611).—This is a report of experiments with *Coccobacillus acridiorum* in which the so-called "elegant grasshopper" (*Zonocerus elegans*), a nonmigratory species, was used as migratory locusts were not available. The results led the author to conclude that this disease at best can be employed only as a supplementary measure in dealing with an invasion of locusts under the conditions that prevail in South Africa.

Fungus diseases of scale insects and white fly, P. H. ROLFS and H. S. FAWCETT, revised by P. H. ROLFS (*Florida Sta. Bul.* 119, pp. 71-82, figs. 19).—A revised edition of Bulletin 94, previously noted (*E. S. R.*, 20, p. 556).

A study of caprification in *Ficus nota*, C. F. BAKER (*Philippine Jour. Sci., Sect. D*, 8 (1913), No. 2, pp. 63-83, figs. 4).—Following a general discussion of the subject, the author describes several new species of fig insects occurring at Los Baños, namely, *Blastophaga nota*, the normal inhabitant of the gall flowers and active caprifier of *F. nota*; *Agaonella larvalis* n. g. and n. sp., common in *F. nota* and probably a guest in its relation to the *Blastophaga*; *Sycophaga nota*, not at all common in gall figs of *F. nota* and apparently a guest; *Sycoryctes philippinensis*, found in great numbers in November in gall figs of *F. nota*, and thought by the author to be a parasite in its relation to the *Blastophaga*; *Philotrypesis similis*, common in *F. nota*; *P. ashmeadii*, frequent in gall figs and probably parasitic on *Blastophaga*; and *P. collaris*, found occasionally in gall figs and probably parasitic on *Blastophaga*.

Synoptic lists of the male and female fig insects found in *F. nota* are appended.

A systematic outline of the Reduviidæ of North America, S. B. FRACKER (*Proc. Iowa Acad. Sci.*, 19 (1912), pp. 217-252).—This paper consists largely of keys to the genera and species of the "assassin bugs" of North America. A bibliography of the more important literature and an index to the genera and species are included.

The British species of the genus *Macrosiphum*, I and II, F. V. THEOBALD (*Jour. Econ. Biol.*, 8 (1913), Nos. 2, pp. 47-94, figs. 30; 3, pp. 113-154, figs. 29).—In the first paper the author deals with 25 species of aphids of the genus *Macrosiphum* which occur in Great Britain, of which 4 are described as new to science. The second paper deals with 35 additional species, of which 8 are described as new to science.

Report of the entomologists, W. E. RUMSEY and L. M. PEAIRS (*West Virginia Sta. Rpt.* 1912, pp. 20-24).—In experiments conducted with a view to perfecting a spray which will destroy the eggs of the apple aphid when applied while the trees are dormant, a block of 31 2-year-old apple trees on the station grounds was made use of. Applications of lime-sulphur 1:8, soluble oil 1:10. Kiloscale 1:10, blackleaf 40 1:20, and nicotin sulphate 1:65 and weaker strengths of all these were made on March 27. The results seem to indicate that commercial lime-sulphur at the strength of from 1:8 to 1:10 if thoroughly applied will destroy the winter eggs of the aphid. In tests made of summer sprays, including soluble oil 1:36 and 1:45, lime-sulphur 1:45, and nicotin sulphate 1:900 applied May 26, and of several combination sprays applied June 7, the nicotin sulphate gave decidedly the best results, killing the aphid without damaging the trees.

The so-called aerostatic hairs of certain lepidopterous larvæ, W. A. RILEY (*Science, n. ser.*, 37 (1913), No. 958, pp. 715, 716).—Attention is called to the fact that it appears to have been very clearly established that the so-called aerophores do not aid in rendering the larvæ more buoyant, but that they contain a poisonous fluid which serves to protect the caterpillars against insectivorous birds.

On the parthenogenesis and oviposition of the potato tuber moth (*Phthorimæa operculella*), F. PICARD (*Compt. Rend. Acad. Sci. [Paris]*, 156 (1913), No. 14, pp. 1097-1099).—When placed with potato tubers the moths were found to oviposit in from 1 to 2 days following mating, from 40 to 80 eggs being deposited within 1 to 3 days. The moth is said to oviposit on a large number of solanaceous plants, on rugous surfaces and in the depressions about the

buds of the tubers, accidental cracks in the surface of the tuber, depressions along the nervures of the leaves, etc.

The author has found parthenogenesis to occur in but 9 cases out of more than 100 which he has observed. Altogether but 23 females and 21 males were produced parthenogenetically by these 9 females, as many of the eggs deposited did not hatch. Forty is said to be the maximum number of eggs deposited by unfertile moths; these moths live much longer than the fertile ones. During July and August the life cycle was passed within a month, but with the parthenogenetic generation from 1½ to 3 months were required for the same development.

The insects of the dipterous family Phoridae in the United States National Museum, J. R. MALLOCH (*Proc. U. S. Nat. Mus.*, 43 (1913), pp. 411-529, pls. 7).—Two genera and 92 species are described as new. The paper includes a list of the species the habits of which are more or less known.

Descriptions of new genera and species of muscoid flies from the Andean and Pacific coast regions of South America, C. H. T. TOWNSEND (*Proc. U. S. Nat. Mus.*, 43 (1913), pp. 301-367).—This paper contains descriptions of 72 species of muscoid flies of South America. See also a previous note (E. S. R., 26, p. 860).

Merodon equestris in southern British Columbia, P. NORMAN (*Proc. Brit. Columbia Ent. Soc., n. ser.*, 1911, No. 1, pp. 22-26).—The narcissus fly (*M. equestris*) is said to have been imported into British Columbia about 6 years ago. The adult is active from the end of March to the beginning of September, but practically all the injury is done during the month of May. Upon hatching out from the egg, which appears to be deposited in the center of the crown of leaves, the larva enters the bulb, where 6 months are passed in the larval stage and where it hibernates. In February it leaves the bulb and pupates about half an inch below the surface of the soil, emerging as an adult toward the end of March.

The southern corn rootworm, or budworm, F. M. WEBSTER (*U. S. Dept. Agr. Bul.* 5, pp. 11, figs. 2).—A summarized account of the literature, together with recent observations of *Diabrotica duodecimpunctata*, its distribution, food plants, injury, habits of the larvæ, oviposition, seasonal history, natural enemies, and remedial and preventive measures.

The western corn rootworm, F. M. WEBSTER (*U. S. Dept. Agr. Bul.* 8, pp. 8, figs. 5).—A summarized account of *Diabrotica longicornis* similar to that of *D. duodecimpunctata* above noted.

The coconut leaf-miner beetle, *Promecotheca cumingii*, C. R. JONES (*Philippine Jour. Sci., Sect. D*, 8 (1913), No. 2, pp. 127-133, pls. 2; *Philippine Agr. Rev. [English Ed.]*, 6 (1913), No. 5, pp. 228-233, pl. 1, fig. 1).—This beetle is said to be a source of injury through feeding, both in the adult and larval stages, upon the leaves of the young coconut. The author here presents an account of its life history and habits and methods of control. Observations have shown that a little over 44 per cent of the larvæ and pupæ and an average of about 5 per cent of the eggs are parasitized.

The occurrence of a cotton boll weevil in Arizona, W. D. PIERCE (*U. S. Dept. Agr., Jour. Agr. Research*, 1 (1913), No. 2, pp. 89-98, pl. 1, figs. 9).—This is a report of studies made by the author during August, 1913, in association with A. W. Morrill, of the Arizona Experiment Station, as to the occurrence of a boll weevil, which had previously been discovered by O. F. Cook and H. B. Wright, and reported by the former (E. S. R., 29, p. 458), as developing upon *Thurberia thespesioides* in Arizona. The weevil has been found to occur in Ventana Canyon, Santa Catalina Mountains, and in Stone Cabin and Sawmill Canyons, in the Santa Rita Mountains, where it breeds commonly upon

T. thespesioides, a plant so nearly like cotton that the Mexicans and natives call it wild cotton.

A close examination of this weevil has disclosed many minor points of difference from the usual form of the cotton boll weevil (*Anthonomus grandis*). The Arizona form may be found in hibernation in cells until September 1, while the eastern form is never found in cells in cotton bolls after March 15. On *Thurberia* the Arizona form seems to be confined to one or not more than two annual generations and is found at an altitude of 4,000 ft. and higher, while the cotton boll weevil has many generations and has never been found above an altitude of 2,000 ft. Experiments have shown that the cotton boll weevil will readily and eagerly feed upon *Thurberia* squares and bolls and that the *Thurberia* weevil will feed upon and develop in cotton squares. It is stated that B. R. Coad has succeeded in rearing undoubted crosses between the two varieties from females of each form, although these hybrid offspring were somewhat undersized.

The evidence presented has led the author to conclude that the two forms represent merely two subspecies, or varieties, or geographic races of a single species, and he here describes the Arizona form as a new variety under the name *A. grandis thurberiae*.

It is not known whether the *Thurberia* weevil hibernates as an adult outside of its cell, but it has been found that many individuals pass the winter and even the summer in the cells formed during the preceding fall. The natural dormant period of the Arizona weevil lasts about 9 months. *Thurberia* weevils extracted from their cells in May and sent to Victoria, Tex., immediately began to feed and develop upon cotton and produced several generations. Thus the *Thurberia* weevil has either acquired by long years of adversity an ability to survive for a longer period without food, assuming *A. grandis* to be the original species, or, if the *Thurberia* weevil is the true original form, then the ability to obtain a plentiful supply of early food has caused the species to lose some of its resistance to adversity. The development of the *Thurberia* weevil on its native host has not been studied, but it has been observed at Victoria on cotton and the period required for its development found to be practically the same as for the cotton boll weevil. *Thurberia* weevils removed from hibernation in June and transplanted on cotton began reproducing at once and continued to do so throughout the season.

The host plant of this new form grows at altitudes of from 2,250 to 7,000 ft. and is found at the bottom of the canyons, on the canyon walls, and on the top of the ridges, growing usually where protected more or less from the greatest heat of the sun. It begins flowering in some localities in July, while in others it is just beginning to bud in the latter part of August. The flowering continues into October. The plants are perennial, growing to over 10 ft. in height with a spread of about 10 ft.

At least two species of parasites, a species of *Cerambycobius* and an undetermined braconid, attack the *Thurberia* weevil in the Santa Rita Mountains.

This new weevil becomes of economic importance in that cotton is now being cultivated under irrigation in several localities in Arizona and in the Imperial and Colorado River valleys in California. *Thurberia* is said to occur in nearly every mountain range in southwestern Arizona where there is any moisture. In the vicinity of the Santa Cruz Valley cotton is grown within 5 miles of *Thurberia* plants, and the weevil was found abundant within not more than 10 miles from such cotton. *Thurberia* is also known to occur in Fish Creek Canyon, one of the sources of the Salt River, in which valley the most extensive cotton plantings in Arizona are found, and in the mountains to the north and south of the Gila River Valley.

Since the weevil will probably cleave to its native food plant until compelled to seek sustenance elsewhere, the author is of the opinion that a wholesale destruction of the native food plant might invite a quicker than natural adaptation to cotton on the part of this weevil. It is thought that the introduction of parasites of the cotton boll weevil would be of considerable assistance in reducing the Arizona weevil and that they would not cause its dispersal. It is pointed out that there is danger of a distribution of weevil-infested buds through the drainage system by summer freshets. Attention is called to the fact that it is of extreme importance that the *Thurberia* weevil be kept out of western Texas and any part of the Southeast, since if accidentally introduced into other sections it might be able to stand much greater variations of climate than *A. grandis* and become a much more powerful enemy of cotton.

Life history of *Otiorhynchus ovatus*, the strawberry root weevil, under lower Fraser conditions. R. C. TREHERNE (*Proc. Brit. Columbia Ent. Soc., n. ser., 1912, No. 2, pp. 41-50; abs. in Rev. Appl. Ent., 1 (1913), Ser. A, No. 3, pp. 92-94*).—This insect is reported to have caused considerable loss to growers in the lower Fraser Valley and those sections of British Columbia along the Pacific coast where strawberries are grown commercially. It does not appear to attack the crown but feeds on the roots of the plant only, the larva having been found from 6 to 8 in. below the surface. It is said to be far more numerous than is *O. sulcatus*.

The incubation period of the egg is about 21 days, the length of the larval stage at least 7 months, and of the pupal stage from 21 to 24 days. The larva is more or less omnivorous, having been taken in clover and timothy grass sod, on wild strawberry from sea level up to an elevation of 500 ft., on the roots of the peach, on rhubarb, *Rumex acetosella*, *Potentilla glandulosa*, *Balsamorhiza sagittata*, *Poa serotina*, and *P. pratensis*; it has also been found in potato fields, though there is no direct proof of its attacking potato. The larvae attack the plant roots by making longitudinal slits in portions of the epidermis, subsequently girdling the roots either directly or in a spiral manner. The most serious injury is done in early spring when the larvae are nearly full grown and attack the main roots, which are sometimes cut off 2 in. or so from the crown.

The pupal stage is passed at from 4 to 6 in. or even 8 in. below the surface. The female deposits some 50 eggs within a period of 4 to 5 days; this period may be extended to as long as 15 days. Oviposition takes place from the end of June to the end of August, varying somewhat according to the season.

Strawberries grown on the matted row system are not as a rule seriously affected the first year after planting, unless the soil was previously infested by the insect. The injury is noticeable the third summer, often reducing the crop fully 50 crates to the acre.

The following remedial measures are suggested: The growth of strong varieties; the running of chickens over the grounds; trapping the adult weevils under boards (only useful to small growers); the use of some sticky material as traps; spraying with arsenate of lead (only useful after the first crop is harvested and when the weevils are very numerous); chemical remedies, potassium cyanid and carbon bisulphid, but the author is doubtful whether any remedy of this kind can be used to kill the eggs, larvae, or adults which will not at the same time destroy the plant; burning the plants immediately after the first crop has been gathered by covering them with dry straw and setting fire to it; plowing at the end of July or at the beginning of August, with frequent cultivation previous to or during the winter; autumn planting; plant renewal during the middle of the second summer; and 1-year crops instead of 2-year crops, though this is not satisfactory. Rotation of crops is strongly advocated in the following order, derived from local experience—strawberries, potatoes, and rhubarb.

Not more than 1 acre in 10 should be laid down to strawberries in an infected locality.

Annual report of the Bee-Keepers' Association of the Province of Ontario, 1912 (*Ann. Rpt. Bee Keepers' Assoc. Ontario, 1912*, pp. 72).—This consists of the proceedings of the annual meeting, held at Toronto in November, 1912.

The Bombidæ of the New World, II, H. J. FRANKLIN (*Trans. Amer. Ent. Soc.*, 39 (1913), No. 2, pp. 73-200, pls. 22).—This second part of the work previously noted (*E. S. R.*, 28, p. 758) deals with the species occurring south of the United States. Tables are given for the determination of queens, workers, and males of American species of *Bombus* south of the northern boundary of Mexico, of which 9 species are described as new to science. It is stated that females and males of but 2 species of *Psithyrus* each have so far as known been collected in the New World south of the United States, one of the males having not hitherto been described. A list of unclassified names and descriptions is appended.

Studies in the wood wasp superfamily Oryssioidea, with descriptions of new species, S. A. ROHWER (*Proc. U. S. Nat. Mus.*, 43 (1913), pp. 141-158, pls. 2, figs. 6).—This contribution from the Bureau of Entomology of this Department deals with the habits, geographical distribution, external anatomy, relationships, and classification of the superfamily.

A study in insect parasitism, R. L. WEBSTER (*Proc. Iowa Acad. Sci.*, 19 (1912), pp. 209-213).—This paper reports studies made at the Iowa Experiment Station of parasitism of the southern tobacco worm (*Phlegethontius sexta*), a pest commonly met with in Iowa on the tomato and potato.

The braconid *Apanteles congregatus*, its most common primary parasite, was found to be highly parasitized by the two hyperparasites *Mesochorus luteipes* and *Hypopteromalus viridescens*. Six different lots consisting of a total of 2,393 *Apanteles* were collected from September 7 to October 18. *Apanteles* developed from 1,112, *Hypopteromalus* from 779, and *Mesochorus* from 27, leaving 475 from which nothing was reared.

A revision of the Ichneumonidæ based on the collection in the British Museum (Natural History), with descriptions of new genera and species, C. MORLEY (*London, 1913*, pt. 2, pp. IX+140, pl. 1).—This second part of the work previously noted (*E. S. R.*, 27, p. 662) deals with the tribes Rhyssides and Echthromorphides of the subfamily Pimplinæ and Anomalides and Paniscides of the subfamily Ophioninæ.

Descriptions of new Hymenoptera, V, J. C. CRAWFORD (*Proc. U. S. Nat. Mus.*, 43 (1913), pp. 163-188, figs. 2).—Among the 2 genera and 30 species here described as new to science are *Eurytoma piura* and *Cerambycobius townsendi*, both reared from the Peruvian cotton square-weevil (*Anthonomus vestitus*) in Peru; *Coccidoctonus trinidadensis*, reared from *Pulvinaria pyriformis* on honey-suckle in Trinidad; *Spintherus pulchripennis*, reared from *Pissodes* sp. at Columbia Falls, Mont.; *Cecidostiba ashmeadi*, a parasite of *Polygraphus rufipennis* at Morgantown, W. Va.; *Cecidostiba thomsoni* from *Pissodes* sp., at Columbia Falls, Mont.; *Catolaccus townsendi* from *A. vestitus* in Peru; *Chrysocharis parksi*, *C. ainsliei*, *Closterocerus utahensis*, *Pleurotropis rugosithorax*, *Derosinus punctiventris*, and *Diaulinus begini*, reared from Diptera of the genus *Agromyza* at Salt Lake City, Utah; *Closterocerus winnemana*, reared from the eggs of *Arge salicis* at Plummer's Island, Maryland; *Diaulynopsis callichroma* and *Diaulinus websteri*, both reared from *Agromyza jucunda* at Tempe, Ariz.; and *Comedo hookeri*, reared from *Pyrophila pyramidoides* at Vienna, Va.

Descriptions of one new family, eight new genera, and thirty-three new species of ichneumon flies, H. L. VIERECK (*Proc. U. S. Nat. Mus.*, 43 (1913), pp. 575-593).—Among the species of economic importance here described as new

to science are *Meteorus archipsidis*, reared from *Archips argyrospila* at Bethany Center, N. Y.; *Rogas laphygma*, reared from *Laphygma frugiperda* at Brownsville, Tex.; *Angitia plutellæ*, reared from *Plutella omissa* at Rocky Ford, Colo.; *Campoplex epinotiæ*, reared from *Epinotia arctostaphylina* at Carmel, Cal.; *C. polychrosidis*, reared from *Polychrosis carduiana* at Hyattsville, Md.; *Cymodusa aristotelis*, parasitic on *Aristotelia pudibundella* at Kirkwood, Mo.; *Herpestomus hyponomeuta*, reared from *Hyponomeuta malinellus* in Japan; *Hypotherentes nigrolincatus*, a parasite of *Heliophila albilinea* at Springer, N. Mex.; etc.

Notes on sawflies, with descriptions of new species, S. A. ROHWER (*Proc. U. S. Nat. Mus.*, 43 (1913), pp. 205-251, figs. 6).—Several of the species here described as new are of economic importance, including *Arge salicis*, the larva of which was taken from *Salix niger*, at Plummer's Island, Maryland; *Diprion grandis*, the larvæ of which feed on *Pinus serotiorum*, at Crawford, Nebr.; and *Perclista quercus*, which defoliates white oaks at Forest Hills, Mass.

The life history of *Ixodes angustus*, S. HADWEN (*Proc. Brit. Columbia Ent. Soc., n. ser.*, 1911, No. 1, pp. 37, 38).—This tick, although found on a variety of animals, in British Columbia occurs principally on squirrels (*Sciurus hudsonius douglasi* and *S. hudsonius vancouverensis*). The life cycle is said to be passed in 221 days.

FOODS—HUMAN NUTRITION.

The municipal abattoir, R. M. ALLEN and J. W. McFARLIN (*Kentucky Sta. Bul.* 173, pp. 213-265, pls. 7, figs. 6).—In connection with the Kentucky state pure food and drug work, an inspection has been carried on of slaughterhouses and meat markets throughout the State, as well as investigations to determine the best remedy for the conditions found, since these could not be controlled by the pure food law and the general health statutes of the State or by the existing city ordinances.

The bulletin makes a strong plea for the municipal abattoir and discusses such questions as building and equipment, city and private ownership, license and inspection fees, the municipal abattoir under the United States laws, and needed state legislation. A proposed ordinance for municipal abattoirs is given and Kentucky plans for a model abattoir. Offal waste, the relation of the municipal abattoir problem to breeder and feeder, and systems of meat inspection are considered and the results of a recent meat conference in Louisville presented. It is stated that since the municipal abattoir question has been under consideration decided change has been noted in the sanitary condition of Kentucky slaughterhouses.

The results of the investigation lead to the conclusion that the "municipal plants should be organized only to the extent of economical and efficient inspection. It would seem that the extent of centralization for inspection can well follow that amount of trade cooperation among the butchers necessary to establish economical slaughtering, refrigeration, tankage, and similar trade advantages. One plant, killing a few animals, can not afford the overhead investment and running expense of modern refrigeration and adequate tankage facilities. A group of butchers can install such equipment, at a great saving to each individual, and thus we should be able to yoke together the necessity for trade economy and cooperation with the necessity for centralized inspection.

"One outstanding point for such investigation is the fact that the wasteful and costly methods on the part of the local butcher, such as the giving away of offal, the purchase and hauling of ice, lower prices for carelessly handled hides and tallow, from small plants and through several middlemen, and the

maintenance of plants and labor, for a few animals, capable of greatly increased slaughterings, afford little or no element of economic competition from the unorganized, uninspected local meat supplies, and these economic errors have a substantial and direct influence in fixing the high meat prices."

Emaciation in meat inspection, F. GRÜTTNER (*Ztschr. Fleisch u. Milchhyg.*, 23 (1913), No. 20, pp. 467-473).—It is the opinion of the author that the whole animal body should be regarded as unfit for human food if complete emaciation has taken place, and that its value as human food is very considerably reduced if emaciation has taken place to any great extent.

The presence of succinic acid in meat extracts and in fresh meat, H. EINEBECK (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 87 (1913), No. 2, pp. 145-158).—The examination of several samples of commercial beef extracts showed the presence of succinic acid in amounts varying from 0.3 to 0.5 per cent. The amount of succinic acid in several samples of fresh beef varied from 0.1 to 0.5 per cent.

Muscle extractives.—XIV, Carnosin and carnosin nitrate, W. GULEWITSCH (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 87 (1913), No. 1, pp. 1-11).—Experimental data are given regarding the optical properties of carnosin and carnosin nitrate which were obtained in pure form from meat extractives. For earlier work, see previous notes (E. S. R., 18, pp. 67, 1067; 19, p. 64).

Muscle extractives.—XV, The presence of carnosins, methylguanidins, and carnitins in horseflesh, J. SMORODINZEW (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 87 (1913), No. 1, pp. 12-20).—The examination of muscle from a freshly killed horse showed the presence of these substances in the following amounts: Carnosin, 1.82; methylguanidin, 0.83; and carnitin, 0.2 per cent.

Fish milt as human food, J. KÖNIG and J. GROSSFELD (*Biochem. Ztschr.*, 54 (1913), No. 5-6, pp. 333-350).—The results are presented of a study of the composition of herring milt and carp milt, special reference being made to the nature of the nitrogenous and fatty constituents.

Among the nitrogen compounds found were the meat bases, xanthin and creatinin, free amino acids, and protamin in combination with nucleic acid. The fat contained about 20 per cent lecithin and from 11 to 17 per cent of cholesterolin.

Fish roe as human food, J. KÖNIG and J. GROSSFELD (*Biochem. Ztschr.*, 54 (1913), No. 5-6, pp. 351-394, pls. 2, fig. 1).—A study was made of the chemical composition of several varieties of fish roe, including among others that of herring, carp, pike, and cod. Several varieties of caviar were also studied.

The fish roe showed a low water content. Among the meat bases found were xanthin and creatin, and among the free amino acids taurin, *l*-tyrosin, and glycocoll. The proteins were rich in sulphur and phosphorus, but protamin was found. The fat showed a high content of lecithin, nearly 60 per cent. and from 3 to 14 per cent of cholesterolin. The lecithin content was highest in the case of the roe with a low fat content. The sulphur and phosphorus were present in organic combination.

Lacto—a frozen dairy product, M. MORTENSEN and B. W. HAMMER (*Iowa Sta. Bul.* 140, pp. 149-155).—This bulletin contains data reported in an earlier publication (E. S. R., 25, p. 63) and new material which has accumulated, including a discussion of the general question of the souring of the milk.

Recent experiments with *Bacillus bulgaricus* show that this organism is capable of forming considerably more acid than the organism ordinarily used as a starter, so the acid fermentation should be watched. By ripening the milk so that it has an acidity of 0.9 per cent, good products, according to the authors, can be obtained with the formulas given. Sometimes this organism gives a disagreeable flavor to the milk which can be overcome in part at least

by the use of the ordinary lactic acid used by the butter maker in conjunction with *B. bulgaricus*.

"The growth of *B. bulgaricus* results in a slimy condition of the milk, the sliminess being so marked with some cultures that the milk can be pulled out in strings several feet long. This stringy condition can be greatly reduced or entirely eliminated by violent agitation. Although this slimy condition is objected to by some persons when the milk is to be used as a drink, it is an advantage when the milk is to be used for making lacto because it improves the body of the product to a considerable extent.

"*B. bulgaricus* grows best at a temperature considerably higher than the temperature ordinarily used for propagating starters. While the best temperature is not exactly known it probably lies above 100° F. A temperature of 99° F., which is one of the temperatures commonly employed in bacteriological laboratories, gives very good results. Cultures can be propagated at room temperatures, but growth is quite slow. . . . If exceptionally clean milk is available, little trouble should be experienced when careful pasteurization is practiced, but if the milk is badly contaminated considerable difficulty is likely to be encountered. An exposure to a steam pressure of 5 lbs. for 15 minutes gave good results with milk that was highly contaminated and with which pasteurization at 180° F. for 2 hours was of no avail in stopping the undesirable changes. . . .

"Another method commonly employed in laboratories consists in heating the milk to the temperature of boiling water for from 20 to 40 minutes on each of 3 successive days. In this procedure, the bacterial spores are supposed to germinate between heatings and, in the vegetative stage, the micro-organisms are killed by the succeeding exposure. This continued heating of course darkens the milk and imparts a cooked taste, but the cooked taste is not as noticeable after fermentation with *B. bulgaricus* as before. . . .

"In various places in the United States a certain micro-organism has been found that is closely related to *B. bulgaricus*. This bacterium produces more acid than the organisms used for starter making, although not so much as *B. bulgaricus*. Moreover, some of the cultures are slimy. Milk fermented by it has an exceptionally clean acid flavor. This organism has also been used to ferment milk for making lacto and an excellent product obtained. It is rather difficult to propagate without the facilities of a laboratory."

Composition and nutritive value of "taralli", a special bread made in Naples, A. CUTOLO (*Bol. Soc. Nat. Napoli*, 2. ser., 24 (1910), pp. 158-164).—Analytical data are given, together with a description of the methods of analysis, and the product is compared with other breads as to composition and nutritive value.

A digestion experiment with banana meal, KAKIZAWA (*Arch. Hyg.*, 80 (1913), No. 7-8, pp. 302-309).—The experiment described was divided into 4 periods of 3 days each. The subject was maintained upon a diet of milk, bread, sausage, cheese, sugar, and butter which furnished a daily ration of approximately 74 gm. protein, 117 gm. fat, and 186 gm. carbohydrate. The greater part of the bread was replaced by banana meal in the second period and by oatmeal in the fourth period.

The coefficient of digestibility of the total dry substance in the food was 90.8 per cent during the banana meal period, 91.9 per cent during the oatmeal period, and 92.3 and 92.6 per cent in the 2 periods where bread was the chief source of carbohydrate. The proportion of the total nitrogenous material in the diet digested during the banana meal period was 88.9 per cent; during the oatmeal period, 86.2 per cent; and during the 2 other periods, 88.3 and 87.6 per cent.

On the nature of the sugars found in the tubers of arrowhead, K. MIYAKE (*Jour. Biol. Chem.*, 15 (1913), No. 2, pp. 221-229).—It was found in the experiments here reported that arrowhead tubers contained both glucose and fructose. The nonreducing sugars were found to consist of sucrose and a sugar which appeared to be raffinose. No evidence was found of the presence of maltose, pentose, and mannose, either free or combined.

Studies on the factors affecting the culinary quality of potatoes, O. BETLER, F. B. MORRISON, and F. E. BOLL (*Jour. Amer. Soc. Agron.*, 5 (1913), No. 1, pp. 1-33, figs. 4).—In this investigation the effect of chemical composition, structure, and methods of cooking and storage on the cooking quality of potatoes was studied. A number of different varieties of potatoes were included in the investigation, each variety being baked, steamed, boiled, and fried. The factors noted in passing upon the quality of the cooked product were discoloration, mealiness, sweetness, and bitterness, the value given to each quality being recorded on the score card. The methods of cooking, judgment of the product, and chemical analysis are discussed in detail. The conclusions drawn are as follows:

Potatoes high in water content are less mealy than those of a relatively low water content. Neither the percentage of starch in a potato nor the ratio of albuminoid nitrogen to starch is indicative of the degree of mealiness. "The presence of sugar in a potato is detrimental to its quality. The percentage, however, that may be tolerated varies with different varieties. The ratio of total nitrogen to starch is no criterion of quality." The degree of development of the tuber is not correlated with quality or mealiness. Fried potatoes are regarded as of better quality than those cooked by any other method, while the quality of boiled and steamed potatoes is about the same.

It is claimed by the authors that the quality of boiled potatoes is affected by the temperature at which they have been stored to a greater degree than are potatoes cooked in any other way. Potatoes of fair or poor quality are best stored at 20° C., and the quality of all potatoes is injured by storing at as low temperatures as 1 to 5° C. "Potatoes for culinary purposes should be stored in a dry cellar at 8 to 10° C."

The authors claim that mealiness in the potato is due to the separation of the cells in cooking rather than to their disintegration due to the swelling of the starch grains.

Chemistry of the household, MARGARET E. DODD (*Chicago, 1911, pp. 12+169, pls. 12, figs. 31*).—A discussion is given of some of the chemical principles involved in the more common processes of the household, including the chemistry of water, combustion and fuels, lighting, foods, cooking, laundry, cleaning, etc.

Handbook of hygiene.—III, Food and nutrition, edited by T. WEYL (*Handbuch der Hygiene*.—3. Band, *Nahrungsmittel und Ernährung*. Leipzig, 1913, 2. ed., pp. [VIII]+297+XII+298-478+VI+479-593, figs. 55).—Parts 1 and 2 have already been noted (*E. S. R.*, 23, p. 461). Parts 3 and 4 (pp. 293-593) contain, respectively, Hygiene of Nutrition of Individuals and Groups, by W. Schumburg, and Hygiene of the Alcohol Question, by A. Delbrück, and the general index to the whole volume.

A further contribution to the knowledge of beri-beri, W. CASPARI and M. MOSZKOWSKI (*Berlin. Klin. Wchnschr.*, 50 (1913), No. 33, pp. 1515-1519).—The results are reported of a metabolism experiment in which one of the authors subsisted for several months on a diet the chief constituent of which was polished rice.

Symptoms were developed which suggested the cardiac form of beri-beri, but disappeared very shortly after a small amount of extract of rice bran was added to the diet.

Control experiments were carried out at the same time with pigeons and animals, under the same conditions, and gave similar results. In these experiments evidence was found which pointed to a great destruction of albumin, which the authors claim could only be explained as the result of severe intoxication. This they claim is confirmed by experiments in which birds were maintained in good health for several months upon a diet consisting of hen's eggs, with small amounts of salt and sugar. When polished rice was added to the egg diet in the case of a part of the pigeons, every one of those receiving the polished rice developed symptoms of beri-beri, while the control animals which received only the egg diet developed no such symptoms.

The authors conclude from these results that beri-beri is not due to the lack of some substance in the diet, but to the presence of some toxic substance, and is therefore an intoxication. The beneficial results obtained by the use of purgatives by other authors in an experimental study of beri-beri are in accord with this view.

A typhoid outbreak apparently due to polluted water cress (*Engin. News*, 70 (1913), No. 7, p. 322, fig. 1).—A report of an epidemic of typhoid fever which was apparently caused by eating polluted water cress is given.

Lessons from a probable water cress typhoid outbreak (*Engin. News*, 70 (1913), No. 7, pp. 311, 312).—The necessity for greater care to prevent the contamination of vegetable foods which are to be eaten in an uncooked condition is emphasized. See abstract above.

The relation of growth to the chemical constituents of the diet, T. B. OSBORNE and L. B. MENDEL (*Jour. Biol. Chem.*, 15 (1913), No. 2, pp. 311-326, figs. 7).—Experiments are reported in continuation of previous work (E. S. R., 25, p. 864; 28, pp. 863, 864).

Animals fed upon a diet of purified protein, starch, lard, and protein-free milk, which had grown abnormally for some time and then ceased to grow and declined, were restored to a satisfactory condition of growth by the use of milk or by replacing a part of the lard in the diet with unsalted butter. The work is to be continued.

Studies on the metabolism of ammonium salts, I, II, III (*Jour. Biol. Chem.*, 15 (1913), No. 2, pp. 327-335, 337-339, 341-355).—This includes 3 papers.

I. *The elimination of ingested ammonium salts in the dog upon an adequate mixed diet*, F. P. Underhill (pp. 327-335).—It was found in these experiments that the ingestion of the ammonium salts of several organic acids failed to increase the amount of ammonia nitrogen excreted in the urine, while under comparable conditions the ingestion of the ammonium salts of several inorganic acids caused an increase in the output of ammonia nitrogen, which varied with the different acids. No explanation is given for this temporary retention of the ammonium salts. All of the inorganic ammonium salts tested and some of the organic ammonium salts caused an increase of the total nitrogen excretion above the normal and temporarily stimulated nitrogen catabolism. Sodium chlorid caused a lowering of the amount of ammonia nitrogen eliminated.

II. *A note on the elimination of ingested ammonium salts during a period of prolonged inanition*, F. P. Underhill (pp. 337-339).—The ingestion of ammonium carbonate by a starving animal failed to cause any increase in the urinary excretion of ammonia nitrogen. Ammonium chlorid, however, caused a distinct increase in the output of ammonia nitrogen as well as of total nitrogen. The output of both ammonia nitrogen and total nitrogen remained for some time at a high level.

III. *The utilization of ammonium salts with a nonnitrogenous diet*, F. P. Underhill and S. Goldschmidt (pp. 341-355).—In the case of dogs maintained upon a nonnitrogenous diet of high energy value the ingestion of ammonium

chlorid showed no retention of nitrogen. This is contrary to the results obtained by other workers. The conclusion is reached that ammonium chlorid is incapable of acting as a source of nitrogen supply for the body. It would appear from these experiments that in considering the influence of ammonium salts upon metabolism distinction must be made between the organic and the inorganic ammonium salts.

The amount of indol obtained by artificial digestion and decay of different proteids, W. VON MORACZEWSKI (*Biochem. Ztschr.*, 51 (1913), No. 4, pp. 340-354).—The author determined the quantity of indol obtained from artificial digestion of casein, the effect of sugar, fat, etc., upon the amount formed, and particularly the conditions of indol formation, namely, pancreatic digestion and putrefaction. Other proteid substances, including thymus, egg white, egg yolk, serum globulin, lactalbumin, fibrin, brain, edestin, meat of different sorts, lentils, etc., were subjected to digestion and to putrefaction and the quantities of indol specific for each were measured.

The influence of the diet on the excretion of indol and indican by healthy men, W. VON MORACZEWSKI and E. HERZFELD (*Biochem. Ztschr.*, 51 (1913), No. 4, pp. 314-339).—The amount of substance giving an indol reaction obtained from urine by distillation was compared with the indican content of the urine on different diets. An increase was noted on a fat, a vegetable, and a gelatin diet, and a decrease on a carbohydrate and a sugar diet. Adding protein caused an increase as compared with carbohydrate and a decrease as compared with fat.

The indol was determined directly in the feces and also after fermentation. The quantity obtained in both cases was increased by fat and also by a diet rich in protein, while carbohydrates diminished indol in both portions and vegetables protected protein from putrefactive changes. The nitrogen and chlorids of the feces showed the same relation. A direct connection between the indican of the urine and the indol of the feces was often noted, both increasing or diminishing at the same time.

The influence of starvation upon the creatin content of muscle, V. C. MYERS and M. S. FINE (*Jour. Biol. Chem.*, 15 (1913), No. 2, pp. 283-304).—Numerous experiments are reported which are a continuation of previous work (*E. S. R.*, 28, p. 865).

During the early part of starvation the creatin concentration of the muscle is increased, but it decreases at the close of the period, owing to the great loss of creatin in the urine during starvation due to decomposition of the muscle tissue. It is the opinion of the authors that the evidence in support of the view that creatin and creatinin are independent in metabolism is weaker than that in support of the view that urinary creatinin is derived from the muscle creatin.

The influence of carbohydrate feeding upon the creatin content of muscle, V. C. MYERS and M. S. FINE (*Jour. Biol. Chem.*, 15 (1913), No. 2, pp. 305-310).—Experiments with animals which were fed almost exclusively upon carbohydrate for varying periods of time showed that the effect of carbohydrate feeding upon the creatin content of the muscle is very similar to that observed in starvation. After a long period of carbohydrate feeding an even greater reduction in the creatin content of the muscle than that which occurs in starvation may be observed. The decreased elimination of creatin after carbohydrate feeding is due to the sparing action of carbohydrate on protein metabolism.

Calorimetry of the work of the kidneys, F. TANGL (*Biochem. Ztschr.*, 53 (1913), No. 1-2, pp. 36-40).—Experiments carried out with the calorimeter, described in the following article, indicated that 8.2 per cent of the total heat

production of the animal body could be attributed to the work of the kidneys, in the case of the rat, and 7.9 per cent in the case of the dog.

A calorimeter for small animals, F. TANGL (*Biochem. Ztschr.*, 53 (1913), No. 1-2, pp. 21-35, figs. 3).—A description is given of a small calorimeter of the open-circuit type which consists essentially of two small copper cylinders inserted in Dewar flasks, which, in turn, are inclosed in a copper box with cork insulation.

The difference in temperature between the two cylinders is measured by means of thermoelectric junctions connected to a galvanometer. One of the cylinders contains a rheostat and in the other is placed the animal whose heat production is to be studied. During an experiment electricity is supplied to the rheostat to generate a quantity of heat sufficient to compensate that given off by the animal in the other cylinder, and thus the two cylinders are kept at the same temperature. The amount of heat produced by the subject is determined from the amount of current supplied to the rheostat.

Provision is also made for the measurement of the carbon dioxide and water vapor produced during the experiment, so that the instrument may serve both as calorimeter and respiratory apparatus.

Micro-calorimeter for the determination of the heat production of bacteria, K. von KÖRÖSY (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 86 (1913), No. 5, pp. 383-400, figs. 2).—A description is given of a micro-calorimeter which utilizes the heat of vaporization of ether as a means of indicating the heat production. The number of calories developed by the subject is measured directly by the amount of ether distilled over during the experiment.

ANIMAL PRODUCTION.

The measurement of the intensity of inbreeding, R. PEARL (*Laine Sta. Bul.* 215, pp. 123-138).—In this treatise is presented "a general method of measuring the intensity or degree of the inbreeding practiced in any particular case." On the basis that "the inbred individual possesses fewer different ancestors than the maximum possible number," the author presents the following formula for determining a coefficient of inbreeding:

$$Z_n = \frac{100 (p_{n+1} - q_{n+1})}{p_{n+1}}$$

in which p_{n+1} denotes the maximum possible number of different individuals involved in the matings of the $n+1$ generation and q_{n+1} the actual number of different individuals involved in these matings. It is evident that the coefficient of inbreeding Z is the percentage of the difference between the maximum possible number of ancestors and the actual number realized. In this method the author starts with the individual in question and works backward, assuming that all the different individuals are entirely unrelated until the contrary is proved by the finding of a common ancestor.

In the mating of brother with sister for a series of generations, it is shown that "in the last 2 ancestral generations \times is 50 per cent inbred; in the last 3 generations it is 75 per cent inbred; and in the last 4 generations it is 87.5 per cent inbred." After the seventh generation there is relatively little change made by further generations of this sort of breeding. It is shown that "while increase in intensity of inbreeding is not so rapid in the first few ancestral generations by parent \times offspring type of breeding as with brother \times sister type, by the time the tenth ancestral generation is reached the values are, for practical purposes, the same."

In actual pedigree work the method of calculation consists in determining the primary reappearance of individuals, by which is meant a reappearance as the sire or dam of an individual which has not itself appeared before in the lower ancestral generations. These primary reappearances, together with all the foregoing ancestors which they involve, are then enumerated for each generation and the consequent additions substituted in the $(p_{n+1}-q_{n+1})$ position of the formula, while the maximum possible number of ancestors for the particular ancestral generation involved is substituted for p_{n+1} . The result shows the percentage of inbreeding. The author demonstrates the relation of the coefficients of inbreeding to the hereditary constitution of the individual.

It is believed that this method "is equally applicable to all pedigrees and to all degrees and types of inbreeding"; and that "the proposed coefficients of inbreeding may be made extremely useful in studies of the problem of the effect of inbreeding, whether in relation to its purely theoretical aspects, or in the practical fields of stock breeding and eugenics."

A contribution toward an analysis of the problem of inbreeding, R. PEARL (*Amer. Nat.*, 47 (1913), No. 562, pp. 577-614, figs. 2).—This article is an elaboration on material reported above.

The feeding of farm animals, O. KELLNER (*Die Ernährung der Landwirtschaftlichen Nutztiere*. Berlin, 1912, 6. ed., rev. and enl., pp. XII+640).—This is the sixth edition of this treatise, revised and enlarged (E. S. R., 17, p. 63). It comprises a very comprehensive study of the feeding of domestic animals and includes summarized accounts of feeding experiments previously reported from other sources.

The development of agricultural feeding knowledge, F. HONCAMP (*Landw. Vers. Stat.*, 79-80 (1913), pp. 1-70).—In this treatise the author outlines in a general way the work of the various German investigators in animal nutrition and the various steps in the development of general feeding knowledge.

Results of nuclein feeding of animals (*Tierärztl. Zentbl.*, 36 (1913), Nos. 25, pp. 384-389; 26, pp. 401-405).—A special feed (lavocat), rich in nuclein and of a high phosphorus content, when fed to horses and cattle proved of value as a stimulant and body builder. This was especially true of old horses, young calves, and animals affected with digestive ailments.

[The value of calcium chlorid in animal production], R. EMMERICH and O. LÖEW (*Deut. Landw. Tierzucht*, 17 (1913), No. 28, pp. 333-335).—Experiments in feeding calcium chlorid to calves and pigs resulted in an increase in weight of from 10 to 25 per cent as compared with animals on feeds lacking in this element. In these experiments the calcium chlorid was added to the drinking water, and the feed included fish meal and skim milk, both relatively high in calcium.

On the values of feeding materials, F. MACH (*Landw. Vers. Stat.*, 79-80 (1913), pp. 815-846, fig. 1).—This reports analyses of sesame cake, poppy cake, palm-seed cake, oil cake, and rice meal, with comments and tables on the relative market value of these and other concentrate feeds as determined by their feeding value.

Inspection of commercial feeding stuffs, P. H. SMITH and C. L. BEALS (*Massachusetts Sta. Bul.* 146, pp. 3-61).—This bulletin contains analyses and discussion of the following commercial feeding stuffs: Cotton-seed meal, linseed meal, gluten meal, gluten feed, distillers' dried grains, malt sprouts, brewers' dried grains, wheat middlings, wheat bran, rye feeds, molasses feeds, calf meals, puffed wheat, corn meal, ground oats, rye meal, hominy meal, provender, dried beet pulp, corn bran, meat scraps, meat and bone meal, blood meal, fish meal, milk albumin, alfalfa meal, and proprietary mixed feeds.

There is included a tabulation of wholesale market prices of commercial feeding stuffs for 1912-13.

Inspection of feeding stuffs (*New York State Sta. Bul. 366, pp. 235-356*).—This bulletin contains analyses of the following commercial feeding stuffs: Cotton-seed meal, linseed meal, malt sprouts, dried distillers' grains, dried brewers' grains, gluten meal, gluten feed, corn bran, hominy feeds, mixed and proprietary feeds, molasses feeds, cotton-seed feeds, poultry and animal feeds, beef scrap, tankage, alfalfa meal, dried beet pulp, peanut bran and meal, buckwheat by-products, corn meal, pea meal, wheat middlings, rolled oats, ground bread, wheat bran, puffed rice, puffed wheat, shredded wheat waste, cob meal, and miscellaneous mixed and proprietary feeds.

There is included a report of tests of the percentage of sand found in feeds compounded with screenings, from 0.13 to 4.2 per cent being found. The text of the New York State law relating to the sale and inspection of feeding stuffs and other data are also given.

Studies in the blood relationship of animals as displayed in the composition of the serum proteins.—II, A comparison of the sera of the ox, sheep, hog, goat, dog, cat, and guinea pig with respect to their content of various proteins, J. H. WOOLSEY (*Jour. Biol. Chem.*, 14 (1913), No. 5, pp. 433-439).—The following table summarizes the average results obtained in a comparison of the sera of various animals:

Proportions of the various proteins in animal sera.

Kind of protein.	Ox serum.	Sheep serum.	Hog serum.	Goat serum.	Dog serum.	Cat serum.	Guinea pig serum.
	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Per cent.</i>
"Insoluble" globulin.....	8.1	6.4	6.0	6.5	7.7	6.5	4.2
Total globulin.....	29.0	17.0	36.0	22.0	18.0	30.0	16.0
Total albumin.....	70.0	82.0	64.0	75.0	81.0	69.0	84.0

Notes on native live stock, J. B. THOMPSON (*Guam Sta. Rpt. 1912, pp. 8-22, pls. 4, figs. 5*).—The native stock of Guam is of an inferior grade due to a lack of care and to indiscriminate inbreeding. The prevailing type is the straight-backed, humpless *taurus* species, with occasional indications of zebu intermixture. The cattle are employed for draft, carriage, saddle, beef, and dairy purposes. Their milk-producing qualities are inferior, due to a lack of nitrogenous feed and little effort to develop dairy strains. The native cattle have good active grazing habits and fatten easily on pasture. They are hardy and well adapted to climatic conditions.

The prospects for success in cattle raising are deemed good, owing to the demand for beef, prices paid, the large areas of grazing land, the green feed available throughout the year, and the tropical climate. No contagious or infectious diseases are observed among cattle in Guam, and although both the Texas cattle tick and Australian cattle tick are present, the native cattle are immune to Texas fever. A former intermixture of Jersey blood resulted in materially improved dairy stock.

Weights and body measurements of Guam cattle and carabao are reported. The native carabaos do not withstand heat as well as do cattle. They are lower in body temperature, 373 showing an average temperature of 100.7° F., but under exertion, a rapid rise in temperature is noted, 26 animals averaging 104.7° on a hot day in June. For heavy draft work in the mud, the carabao

has no equal, while they are also used for beef and milk, yielding a fair amount of milk rich in fat.

Horses are scarce and the offspring of a poor grade of stock introduced from the Philippines. The domesticated hogs are of 2 types: First, the long, lean, slow-maturing kind, the sows being prolific and good mothers; second, the short, fine-boned, early-maturing type probably from Chinese or Japanese stock, the sows bearing small litters and being poor mothers.

The native chickens are of mixed breeds. They are somewhat larger than the Leghorn, but are poor egg layers. There is a ready demand for both eggs and fowls in the island. Chicken pox and other serious infectious diseases are prevalent.

Pure-bred stock was imported by the station in 1911 from the United States, consisting of 2 Ayrshire bulls and 2 heifers, 4 Morgan fillies and 2 stallions, 2 Berkshire sows and 2 boars, and a pen each of Barred Plymouth Rock and Single-combed Brown Leghorn hens. The object was, first, the acclimatization of a pure-bred strain, and second, the improvement of native stock. One of the bulls died of what was believed to be Texas fever. The remaining animals were hand picked for about 4 months, when it was thought that they had undergone at least partial immunization. Daily temperatures were kept of the cattle for over 6 months, in which periods of abnormally high temperatures were observed in each of the various animals, but the general condition has remained good. The horses, hogs, and chickens are also reported in good condition. The horses are being fed on native roughage. The crossing of the Berkshire on native stock has resulted in an improvement over the ordinary native pig. Troubles due to climatic conditions are being experienced in the use of incubators.

Color inheritance in swine, W. W. SMITH (*Amer. Breeders Mag.*, 4 (1913), No. 2, pp. 113-123, figs. 5).—Experiments in crossing Yorkshire and Berkshire, and Yorkshire and Poland China swine indicated "(1) the complete dominance of the Yorkshire white over the Berkshire or Poland China black in the F_1 or first hybrid generation; (2) a general tendency for the original parent colors to be expressed separately, and in the proportion of 3 dominants to 1 recessive, in the individuals of the F_2 or second hybrid generation."

Hogging down corn.—A successful practice, J. M. EVVARD, W. J. KENNEDY, and H. H. KILDEE (*Iowa Sta. Bul.* 143, pp. 309-354, figs. 5).—This bulletin reports 3 years' experimental work in determining the practicability of allowing hogs to harvest the corn crop, the value of such a system as compared with the dry lot method, and to ascertain the relative importance of different supplemental crops and concentrated feeds when hogs are fed in this way.

Reports received from a large number of farmers to whom inquiries were sent indicate that the hogging down of corn is in common practice and is being found profitable. Experiments testing the value of several supplementary crops when fed in conjunction with hogged-down corn gave the following results with 10 spring shotes per acre:

Returns from hogged-down corn and supplementary crops.

Supplementary crops.	Average daily gain in weight per hog.	Gain of pork accredited per acre.
	Pounds.	Pounds.
Rape and pumpkins.....	0.931	651.7
Soy beans.....	.828	483.8
Canadian field peas.....	.706	333.8
Hairy vetch.....	.418	292.8

The following table shows the comparative returns from supplemented and unsupplemented corn in the field and dry lot, using an average of 11.25 shotes weighing 70 lbs. each per acre:

Comparative returns from supplements in hogging down and dry-lot feeding.

Method of feeding.	Average daily gain in weight per hog.	Cost per 100 lbs. gain, corn at 50 cts..	Net returns per acre, hogs at 6 cts. per pound.	Net value of corn per bushel.	Grain per 100 lbs. live weight daily.
	<i>Pounds.</i>				<i>Pounds.</i>
Hogged down:					
Corn alone.....	0.42	\$5.41	\$2.10	\$0.47	3.37
Corn and 10 per cent meat meal.....	1.23	3.69	18.31	.78	4.79
Corn and soy beans.....	.84	3.87	10.70	.70	3.86
Corn, 10 per cent meat meal, and green rye.....	1.44	3.56	19.27	.87	4.38
Dry lot:					
Corn alone.....	.62	5.43	2.33	.55	4.19
Corn and 10 per cent meat meal.....	1.17	4.35	12.82	.75	4.64

Comparing the average cost of production per 100 lbs. gain with and without the various supplemental crops and feeds, the following results were obtained: Hogged down with soy beans \$2.73, with cowpeas \$2.87, rape and pumpkins \$1.86, Canadian field peas \$4.42, hairy vetch \$5.85, corn without supplement \$3.14, with meat meal \$2.43, and with rye pasture and meat meal \$2.69.

Replies received from a large number of farmers estimate the saving per bushel of corn by the hogging-down method at an average of 6.89 cts. It is the general conclusion that spring farrowed shotes, weighing from 100 to 170 lbs. are the most adaptable to hogging-down conditions, although younger pigs and old sows may be so fed to advantage.

The farmers' reports indicated an average production of 12 lbs. of pork per bushel of corn fed, when hogged down. Actual experiments gave the following results: With standing corn without supplement, 7.76 lbs. per bushel of corn (this is considered low and is accounted for by unfavorable conditions); corn and meat meal 15.73 lbs.; corn, meat meal, and green rye 18.37 lbs.; corn and soy beans 13.05 lbs.; dry lot corn and meat meal 15.30 lbs.; and dry lot corn alone 9.20 lbs. The average size of a field hogged down at one time was reported as 19 acres, carrying approximately 13 hogs per acre. The carrying capacity of an acre of standing corn for a period of 30 days, with shotes weighing from 125 to 150 lbs., is estimated at from 14 to 15 head when corn is yielding 40 bu. per acre, and 21 to 22 head when corn is yielding 60 bu.

The commonly accepted time to turn hogs into the field is when the corn is well dented. The advantages and disadvantages of this method of harvesting the corn crop are discussed, and a method of temporary fencing is described.

Horse breeding and Mendelism, R. MOTLOCH (*Deut. Landw. Tierzucht*, 17 (1913), Nos. 32, pp. 377-380; 33, pp. 389-391).—In this article the author discusses the relative influence of environment and of ancestry upon the characteristics of the individual horse, with especial emphasis on the transmission of acquired characters.

The inheritance of coat color in horses, W. S. ANDERSON (*Amer. Nat.*, 47 (1913), No. 562, pp. 615-624).—After extensive studies of the color markings of 11,739 horses, and from the results obtained by previous investigators, the author concludes that with the exception of black and brown, chestnut behaves as a recessive to all other coat colors in horses. Brown is dominant to chestnut and black and recessive to bay. Gray and roan are dominant to bay. An attempt is made to harmonize the theory that brown is recessive to bay with

the actual results obtained in a mating of brown \times brown which resulted in a large percentage of bays. The author believes that the discrepancy here lies in the interpretation of colors.

Horse breaking in Argentina (*Pastoral Rev.*, 23 (1913), No. 9, pp. 886-888, figs. 3).—An account of horse-breaking methods in use in Argentina, and a comparison with those of Australia.

Studies on inheritance in poultry.—I, The constitution of the White Leghorn breed, P. B. HADLEY, DOROTHY W. CALDWELL, and C. H. MAGOON (*Rhode Island Sta. Bul.* 155, pp. 151-216, pls. 3).—By means of suitable matings of white and dark birds a completely barred pattern was secured in F_2 , and a pure strain of barred fowls has been built up from these barred F_2 individuals. This barring characteristic is thought to have its origin in a factor for barring, present in the gametes of the White Leghorn male, and not as was formerly believed in a heterozygous condition of black and white. Evidence indicates that the White Leghorn male is homozygous for this character, while the female is heterozygous; also that the White Leghorn male carries a factor for black pigmentation. However, the presence of an inhibiting factor, which represses the manifestation of black and is homozygous for the White Leghorn male, naturally brings out the barred pattern. The presence of these inhibiting factors is apparently peculiar to the Leghorn breed of fowls as a whole, but may be used to advantage in controlling the manifestation of a variety of characters in poultry. It is believed that this factor for barring, present in the White Leghorn, accounts for various unexplained phenomena often observed in poultry breeding.

A former discussion has been previously referred to (*E. S. R.*, 29, p. 372).

[**Inbreeding**], J. H. ROBINSON (*Farm Poultry*, 24 (1913), No. 10, pp. 214, 215).—This is a discussion of the beneficial or detrimental effects of inbreeding as applied to poultry raising, in which the author practically contends that it is not interbreeding in itself that is harmful but interbreeding without rigid selection or some change of condition.

Report of the poultryman, H. ARWOOD (*West Virginia Sta. Rpt.* 1912, pp. 57-59).—Uncompleted experiments indicate that chicks are less vigorous when hatched from eggs laid by hens which have been laying heavily for a long time. A decided lack of phosphorus in the rations resulted in a material decrease in the number of eggs laid. The composition of the eggs did not seem to be materially changed. It was demonstrated that the average size of eggs laid by hens varies considerably according to the season, the eggs being heavier during February and March than at any other time; also that the eggs from mature fowls are heavier than eggs from pullets.

Report of poultry conditions in Indiana, A. G. PHILIPS (*Indiana Sta. Circ.* 40, pp. 32, figs. 20).—A report of data collected relative to the poultry conditions in Indiana, in which lists of questions were sent out to 2,000 farmers. These questions related to the extent of business, kind and amount of stock, selection or breeding, housing and yarding, feeding, hatching and rearing, diseases and parasites, management, and marketing of poultry.

The refrigeration of dressed poultry in transit, MARY E. PENNINGTON ET AL. (*U. S. Dept. Agr. Bul.* 17, pp. 35, pl. 1, figs. 19).—The purpose of this investigation was to determine the temperatures prevailing in refrigerator cars hauling dressed poultry throughout the entire transportation period, and to observe the effect of such temperatures on the condition of the poultry when it arrives at the market. The experiments reported, covering a period between August, 1909, and October, 1912, include 120 car-lot shipments of dressed poultry and aggregate 140,000 miles of haul. Six different car lines are represented. The

weather conditions varied, depending upon the season and the territory involved. In all of the work commercial surroundings and commercial routine prevailed. Thermographs, or self-registering thermometers, were used to record the car temperatures throughout the entire transit. When the car was opened for unloading, a laboratory examination was made of samples of the fowls, by estimating the amount of ammoniacal nitrogen in the muscle tissue, as an index of the progress of flesh changes, and the amount of free acid in the fat, since the rise in acidity is an indication of the aging of the whole carcass.

Fresh chickens contain about 0.0110 per cent of ammoniacal nitrogen. It was found that poultry shipped under car temperatures of from 18 to 26° F. showed 0.0120 per cent ammoniacal nitrogen; under 27 to 30°, 0.0122 per cent; 31 to 34°, 0.0131 per cent; and 35 to 39°, 0.0141 per cent. This difference in composition at the end of the railroad haul continues with increasing magnitude throughout the period at the wholesale commission house and at the retailer's, while in the commission house the deterioration in the high temperature shipments is always at least one stage ahead of the low temperature shipments. It is evident that even such excellently handled poultry as comprised these experimental shipments, if exposed to unfavorable temperatures during transportation, receive an impetus toward decay that can not be overcome by subsequent irreproachable treatment on the market.

The results indicate that the most favorable temperature for poultry transportation is less than 31° F. The problem of maintaining this temperature is largely a question of car construction. The many different cars used in these shipments furnished a great variety of sizes, insulations, roofs, doors, ice bunkers, and other elements which are factors in the sum total of efficiency. In calculating the relative efficiency of the cars, a formula was devised which would take into account the various factors of icing, surface exposure of the car, atmospheric temperature, inside temperature, length of time in transit, etc. The insulation of the car in relation to temperature appeared to be its most vulnerable and its most important part, the construction of the ice bunker coming next in importance. Certain types of insulation in the side walls and floors of the cars were found to be preferable to others. The cars with the best insulated and best built roofs proved to be the most efficient. Moist floors were found to be a serious defect in the present construction of cars.

The wire basket type of bunker is thought to be the most efficient, since an abundant air access to ice and salt results in increased efficiency. Likewise the holding back of the brine in the tank bunker increases the ability of the bunker to chill the car and hence results in increased efficiency. These and other points in construction are regarded as the essential features of the most efficient refrigerator car of the future.

DAIRY FARMING—DAIRYING.

A comparison of first, second, and third crop alfalfa hay for milk production, W. E. CARROLL (*Utah Sta. Bul. 126, pp. 153-189*).—In view of the popular disfavor toward second crop alfalfa as a feed for dairy cattle, experiments were conducted during 2 seasons, 1911-12, and 1912-13, with first, second, and third crops of alfalfa to determine the relative value of these crops. In these experiments the alfalfa was fed ad libitum, with a grain mixture of 0.65 lb. daily to each cow per pound of milk fat produced per week. The test periods were from 3 to 4 weeks' duration, and the feed unit system was adopted.

A summary of the feed units consumed and the milk fat produced with the various crops is shown in the following table:

Feed consumption and milk fat production on first, second, and third crop alfalfa hays.

Crop.	Feed units consumed.	Milk fat produced.	Milk fat for 100 feed units consumed.
		Pounds.	Pounds.
First.....	14,055	591	5.00
Second.....	12,835	687	5.35
Third.....	14,120	671	4.75

While these experiments indicate that second crop alfalfa is at least equal in economy to the other crops, it is noted that it is less relished and that other practical difficulties may tend to reduce its actual value.

Manuring for milk, F. WAKERLEY (*Midland Agr. and Dairy Col. Bul. 1, 1912-13, pp. 8, pl. 1*).—A comparison of the feeding values of 2 pastures of 4 acres each, and treated with 10 cwt. ground lime per acre, one being also fertilized with 4 cwt. superphosphate and $1\frac{1}{2}$ cwt. sulphate of potash per acre. The total yield of milk during the 3 seasons, 1910-1912, was 8,740 lbs. on the unmanured and 13,661 lbs. on the manured pasture.

Winter feeding of dairy cows, J. MACKINTOSH (*Jour. Southeast. Agr. Col. Wye, 1912, No. 21, pp. 57-82*).—In this article the author attempts to outline a rational system of dairy cattle feeding, in which he discusses the Kellner, Armsby, Hansson, and Haecker standards of feeding and suggests a number of successful dairy rations involving home-grown feeds.

The original St. Lambert Jerseys.—An account of their breeding, C. CLARK (*Kimball's Dairy Farmer, 11 (1913), No. 18, pp. 542-545, figs. 10*).—The author reviews the foundation, development, and capabilities of the St. Lambert strain of Jersey cattle, and compares this American-bred type with the finer boned Jersey Island-bred type.

Comparative experiment between Red Danish milch cattle, Jersey cattle, and Dano-Jersey cattle, J. J. DUNNE (*Hoard's Dairyman, 46 (1913), No. 9, pp. 234, 235*).—Comparing these 3 groups, consisting of 15 cows each of approximately the same age, during a period of 2 seasons as regards their average yields and cost of production, the results as summarized in the following table were obtained:

Average yearly yield and cost of production per cow.

Kind of cows.	Yield of milk.	Yield of milk fat.	Yield of butter.	Feed units consumed.	Cost of a home-grown feed unit.
	Pounds.	Per cent.	Pounds.		Cents.
Red Danish.....	8,183	3.53	321.6	6,114	1.63
Jersey.....	4,343	5.69	279.6	4,799	1.66
Dano-Jersey.....	6,327	4.32	306.8	5,375	1.72

In churning and buttermaking experiments the Jersey butter was firmer and harder than the Red Danish, due to a lower olein content, but the feeding of rape oil reduced this hard and brittle consistency.

Milking capacities of the Trinidad government farm cows, H. S. SHREWSBURY (*West Indian Bul.*, 13 (1913), No. 3, pp. 281-287).—Half-bred zebus produced an average daily milk yield of 5.6 qt., testing 3.37 per cent fat, and are reported as good dairy animals for that locality.

Dairying in Jamaica, H. H. COUSINS (*Bul. Dept. Agr. Jamaica, n. ser.*, 2 (1913), No. 7, pp. 253-296, pls. 10).—A general treatise on dairying conditions in Jamaica, in which the author outlines methods of improvement of the native stock. It is noted that importations of pure-bred stock are being made from North America. The Guernsey is given preference as a foundation stock for the purely dairy animal, while the Red Poll has proved valuable as a dual purpose breed. Analyses of the milk of various breeds and crossbreeds are given.

Ninth biennial report of the state dairy bureau [for the biennial period ending November 30, 1912] (*Bienn. Rpt. State Dairy Bur. Cal.*, 9 (1911-12), pp. 49, figs. 9).—A general report of dairying opportunities in California, with statistics on the milk, butter, and cheese output, and a list of creameries in operation in the State.

Quarterly report of the dairy and food commissioner of Virginia, W. D. SAUNDERS (*Quart. Rpt. Dairy and Food Comr. Va.*, 1913, Mar.-May, pp. 43-46, 50-55, 62-68).—This report includes an inspection of 114 dairies and dairy farms and of a number of creameries, collecting stations, and cheese factories, also the examination of misbranded, adulterated, and otherwise illegal stock feeds.

Michigan's new milk and cream law, R. G. KIRBY (*Mich. Farmer*, 141 (1913), No. 8, p. 1, figs. 2).—An account of the new Michigan milk and cream law looking toward sanitation in the dairy and increased purity of the milk.

Milk and cream testing, H. H. DEAN (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm*, 38 (1912), pp. 70-83).—This continues work previously reported (*E. S. R.*, 27, p. 777).

In comparison of the results obtained from the sampling of cream for composite samples by the aliquot and ounce methods, it was found that on a delivery of over 1,400 lbs. fat the total difference by the 2 methods was 8.9 lbs. in favor of the ounce method. Open bottle samples of cream gave "results altogether too high and show very forcibly the need of keeping composite bottles tightly stoppered." Composite samples kept in cold storage proved to be in better condition at the end of one month than were those kept at room temperature. Contrary to expectation, samples kept in cold storage frequently tested "a higher percentage of fat than did those kept at room temperature," this being probably due to the more accurate sampling possible with this better cream. Comparing daily, weekly, semi-monthly, and monthly tests for accuracy of results, it is concluded that the last 3 methods "will credit patrons with approximately correct weights of fat delivered, as compared with testing each and every delivery of cream to the creamery." Tests of 3 different cream scales indicated that a sample of cream may be tested within about 0.2 per cent of accuracy on a 12-bottle cream scale, irrespective of the number of the bottles weighed at one time.

Tests with formalin as a preservative in composite milk and cream samples "show that about one-half a cubic centimeter of formalin will preserve a pint sample of milk or cream in good condition for testing for a month. When 1 cc. of formalin was used the tests were not satisfactory unless an extra volume of sulphuric acid was used (20 and 21 cc. instead of 17.5 cc.)."

It was found that the greatest differences in the cream transported in an ordinary can and a jacketed can was 6° F. in temperature and 0.05 per cent acidity in favor of the cream in a jacketed can. The average difference was 3.6° in temperature and 0.022 per cent acidity. As a rule, there was not sufficient

decrease in the acidity of the cream in the jacketed can to pay for the extra expense and inconvenience.

Tests for 2 years indicate that the average cost of pasteurizing cream for the manufacture of 100 lbs. of butter is 3.3 cts. A combined pasteurizer and cream vat, it is said, gave satisfactory results in reducing the cost of labor in heating and cooling milk and cream. Results from stirring milk while cooling *v.* not stirring indicated that "there was little or no difference in the temperature of the milk in the cans not stirred, comparing milk in the center of the can with that near the outside, or 6 in. from the outside. The milk cooled more rapidly when stirred, and had slightly less acid the following morning, but there was very little difference in the general condition of the 2 lots. Under ordinary conditions in the case of milk for cheese making it would seem as if stirring were not necessary, except where more rapid cooling is desired."

Butter making, H. H. DEAN (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm*, 38 (1912), pp. 83-91).—Continuing work previously noted (*E. S. R.*, 27, p. 779), the effect of neutralizers of acidity in cream for butter making was studied, with the result that "butter scored about 3 points higher by adding milk lime to the cream before pasteurizing, and $3\frac{1}{2}$ points higher by adding the milk lime after pasteurization, as compared with the scores of butter from similar lots of cream which were not neutralized." The use of a small quantity of concentrated milk lime proved preferable to a larger quantity of limewater. It is suggested that the prevention of the development of acidity by keeping the cream cold and more frequent delivery would prove preferable to the use of a large quantity of "neutralizer."

Comparing the results obtained from the use of raw *v.* pasteurized cream for butter making, it is concluded that "there was a greater loss of fat in the buttermilk from the lots pasteurized. The 'overrun' or yield of butter was less from the lots of cream pasteurized. There was not much difference in the quality of the butter as indicated by the scores. This is different from the results got in previous experiments, and is accounted for by the relatively high scores given to the raw lots when fresh."

With a view to determining to what extent the acidity of the cream pasteurized affected the percentage of fat lost in the buttermilk, a series of experiments was conducted and showed an increased loss of fat in the buttermilk as a consequence of increased acidity of the cream at the time of pasteurization. It is explained that this is probably due to an "increased coagulation of the caseous matter which entangles more of the fat globules and prevents their churning or massing in the form of butter." It is stated that "the cream pasteurized with the higher acidity produced butter which gave a lower average score as compared with butter made from similar cream pasteurized on arrival at the creamery when moderately sweet."

Continuing previous tests on the conditions affecting the salt and moisture in butter, it was found that salt added to butter in a wet condition was "better distributed and more in solution than were the dry salt lots." The average percentage of moisture retained in the finished butter was practically the same with both saltings. Tests on the retention of salt in the butter by the 2 methods do not agree. "Butter churned to about the size of wheat granules contained more moisture and less salt than did similar butters churned to lump size." Grittiness in butter is ascribed to an overabundance of salt. It was found that a saturated salt solution contained, on an average, 29.25 per cent salt, and a table is given showing the percentage of salt that butter with a moisture content ranging from 13.5 to 16 per cent is capable of holding in solution. Quantities of salt ranging from 4.29 to 5.77 lbs. per 100 lbs. butter

were added to churnings, with a resulting retention of salt of from 3.156 to 3.45 lbs., the loss being accounted for in the churn water and on the worker. A loss of moisture and salt in butter was found in the process of printing and packing, and after 1, 2, and 3 months in cold storage there was a steady decrease in moisture content, the salt content remaining fairly uniform.

Some butter-making experiments and analyses, R. CROWE (*Jour. Dept. Agr. Victoria*, 11 (1913), No. 6, pp. 357-366, figs. 4).—In testing the supposed value of salt as a butter preservative it was found that after a period of 5 weeks' storage unsalted butter scored higher than did salted. The author believes that the presence of salt facilitates bacterial development in butter. Analyses of 19,470 samples of Victorian butter showed an average composition of 83.5 per cent fat, 13.84 per cent moisture, 0.76 per cent curd, 1.82 per cent salt, and 0.2 per cent boric acid.

Cheddar cheese investigations and experiments, H. H. DEAN (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm*, 38 (1912), pp. 56-70).—Continuing work previously reported (*E. S. R.*, 27, p. 777), analyses of the milk delivered at Ontario cheeseries during 1912 showed an average casein content of 2.14 per cent, the highest percentage being 2.58, the lowest 1.79; and an average fat content of 3.52 per cent, the highest 4.53, the lowest 2.79 per cent.

Comparing the results of 2 years, 1911 and 1912, one a wet the other a dry season, no apparent effect of season upon the casein and fat content of milk was noted. "The averages for milk fat and casein for the season of 1911 were 3.77 and 2.37; for 1912, 3.61 and 2.18, respectively. . . . These results do not coincide with the theory that a dry, hot season tends to produce milk with low fat and casein contents and a wet season the reverse. As in previous years, the milk during the months of September and October tends to be relatively higher in fat and casein content, due doubtless to advancing lactation among cows, consequently less milk is required to make a pound of cheese than is the case earlier in the season."

In vat tests, the average number of pounds of milk required to make a pound of cheese was 10.79, which is practically the same as for 1911. The lowest amount required was 9.68 lbs. in October, the highest 11.43 lbs. in August. The average number pounds of cheese per pound of fat in milk for the different months proved to be fairly uniform, ranging between 2.43 lbs. for August and 2.58 lbs. for July and October; and per pound of casein 3.9 lbs. in August and 4.15 lbs. in July.

Comparing cheese made from 2 separate vats, one containing milk of low fat and casein content (3.42 and 2.09 per cent), and the other high fat and casein content (3.84 and 2.36 per cent), the following results were obtained:

Production of cheese from milks of high and low fat and casein content.

Kind of milk.	Cheese per pound of fat in milk.	Cheese per pound of casein in milk.	Fat content of cheese.	Average shrinkage.	Cheese per 1,000 pounds milk.	Milk required per pound of cheese.
	<i>Pounds.</i>	<i>Pounds.</i>	<i>Per cent.</i>	<i>Per cent.</i>	<i>Pounds.</i>	<i>Pounds.</i>
Low fat and casein.....	2.64	4.33	35.45	2.803	90.70	11.02
High fat and casein.....	2.50	4.02	36.49	2.801	96.23	10.39

The average percentage of moisture in the cheese was the same for both lots, 3.45.

Comparing cheese made from normal and from overripe milk, it is concluded that "the overripe milk of similar composition to that in normal condition pro-

duced 2.2 lbs. less cheese per 1,000 lbs. of milk. The 2 previous years the differences were 2.4 and 2.5 lbs. less per 1,000 lbs. milk from the overripe lots. Both lots contained practically the same percentages of moisture in both green and ripe cheese. The quality of the cheese was inferior in all cases made from the overripe milks. To increase the yield of cheese and improve the quality it is important that patrons of cheeseries shall cool the milk on the farm so as to have it arrive at the factory in a sweet condition."

No difference was noted as to the effect of acid at time of adding rennet to milk. "An average increase of 0.027 per cent acid in the whey at the time of dipping, or removal of the curd from the whey, reduced the yield of cheese per 100 lbs. of milk by 0.4 lb. Last year the reduction was 0.42 lb., and the previous year it was 0.73 lb. All 3 years' results emphasize the importance of separating curd and whey when comparatively sweet in order to have a 'good average', or lessen the weight of milk required to make 1 lb. of cheese. The lots dipped with high acid had greater loss of fat in the whey, greater shrinkage, less moisture in curd and cheese, and scored an average of nearly one point less."

In determining the effect of varying weights of salt applied to curds (2½, 2½, 2¾ lbs. salt per 1,000 lbs. milk), it was noted that increasing the salt reduced the loss by shrinkage during the ripening. There was a slight decrease in moisture content of the cheese, both green and ripe, as the salt was increased, and the highly salted cheese averaged slightly higher in the scoring.

"Cheese ripened in cold storage retained more of the original moisture in the cheese at the end of one month than did cheese ripened in the ordinary ripening room. Most of the loss of moisture in both lots took place from the first inch of the cheese, which included the rind. The greatest loss was during the first week of ripening. The results of 2 seasons' work agree in showing that the loss of moisture from a cheese during ripening takes place nearly altogether from the surface, and that the moisture in the center of the cheese remains fairly constant for at least a month."

There was less shrinkage in ripening cheese in a room of 40° F., than in one of 60° or 70°. The average percentage of moisture was approximately the same. The quality of the cheese was superior in the lots ripened at the lower temperature.

In a comparison of pasteurized *v.* raw milk or cream, it was concluded that "the yield of cheese was slightly greater by adopting pasteurization for Camembert and cream cheese," there being no difference in the case of Gervais cheese. The moisture content was variable and the results were inconclusive. The quality of cheese was superior in the case of the pasteurized milk or cream.

Caerphilly cheese, MISS G. N. DAVIES (*Jour. Agr. [New Zeal.]*, 7 (1913), No. 1, pp. 40-44, figs. 3).—Directions are given for renneting, cutting, scalding, pitching, vatting, salting, pressing, curing, and other processes in the manufacture of Caerphilly cheese.

VETERINARY MEDICINE.

Protective ferments of the animal organism, E. ABDERHALDEN (*Schutzfermente des tierischen Organismus*. Berlin, 1912, pp. XII+110, figs. 8).—This is a contribution in regard to the methods whereby the animal body protects itself against detrimental body and blood substances and substances foreign to the cells. The subject is treated under the following headings: **Enzymes of the cells**; formation of protective enzymes, including protein substances foreign to the body and the blood with particular reference to anaphylaxis, foreign carbohydrates, fats, nucleoproteids, and nucleins; the origin of protective ferments;

the detection of native body substances foreign to the blood; biological diagnosis of pregnancy; the optical method and its use in pathology; the significance of milk for the suckling; the use of the optical method in the field of infectious diseases; etc. A large bibliography is appended.

Investigations in regard to streptolysin, O. VON HELLENS (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 68 (1913), No. 7, pp. 602-644, figs. 12).—The results of this extensive investigation show that streptolysin formation takes place very rapidly and can be noted 1 hour after inoculation. A maximum formation can take place within 7 to 8 hours. The greatest amount of hemolysin formation, which depends upon the nutrient medium and the strain of bacteria employed, is said to be between the seventh and eighteenth hour. As soon as it reaches its fastigium it begins to decrease, and in the first 24 hours this decrease is very rapid. In the greatest number of cases no hemolysin was noted after 8 to 13 days. In anaerobic cultures streptolysin formation and depreciation take place in almost the same manner as in aerobic cultures. In the latter cases, however, they were produced a little more slowly, and a lower amount was formed.

The best nutrient medium for the streptococcus was a horse serum-bouillon containing from 40 to 50 per cent of a serum inactivated at 56° C. for one-half hour. Rabbit serum (10 per cent) bouillon was inferior to ascitic fluid (33 per cent) bouillon. Only a slight development of streptolysin took place in a plain alkaline peptone bouillon, but when 5 per cent of peptone was added to cultures in other media there was a marked increase, in one case over 300 per cent. Evidently a prolysin (Walbum) is present in such cultures which is destroyed when the bacteria are continuously cultivated in the thermostat. The hemolysin present in serum- and ascitic fluid-bouillon cultures is filterable. The filtrate from horse serum bouillon cultures is from 1.1 to 1.4 times weaker than the cultures themselves.

In human, horse, bovine, sheep, goat, dog, pig, rabbit, guinea pig, and pigeon blood appreciable quantities of antistreptolysin could not be noted. The hemolytic action of streptolysin showed a different intensity at different temperatures, being from 4 to 6 times more active at 37° C. than at room temperature, while at nearly freezing temperature it is practically inactive. The greatest resistance toward hemolysin was noted with the blood of the goat and sheep, that of man, horses, bovines, and pigeons coming next, and this being followed by rabbit, dog, pig, and guinea pig blood. A decoloration of the blood of the horse, bovine, sheep, and goat took place as a result of hemolysis. The blood corpuscles of man, the pig, and the guinea pig were agglutinated in some cases.

The hemolytic principle of streptolysin was soluble in ether, and almost the entire quantity present in the culture could be extracted with this solvent. The streptolysin present in the filtrate was labile and was inactivated rapidly by cooling to -16°, at +4 to 5°, at room temperature, or by heating at 37° or above. Horse serum bouillon streptolysin was the most resistant. The streptolysin extracted from the filtrates was thermostable. The addition of hydrochloric acid seemed to increase the inactivation of streptolysin by heat. The rate of preventing inactivation by sodium hydroxid seemed to bear some relation to the hydrogen ion concentration of the solution.

The laws and rules and regulations governing live stock sanitary control work in Tennessee, 1913-14 (*Nashville: Tenn. Dept. Agr., 1913, pp. 47, fig. 1*).—A compilation of the various laws, rules, and regulations relating to live stock sanitary control work in Tennessee.

The results of meat inspection in Brunswick, 1905-1911, C. SANDER (*Beitr. Statist. Braunschweig, 1913, No. 26, pp. 23-47*).—A statistical report of inspection work.

Conditions influencing the transmission of East Coast fever, G. H. F. NUTTALL and E. HINDLE (*Parasitology*, 6 (1913), No. 3, pp. 321-332).—Experiments in the transmission of East Coast fever here reported led the authors to conclude that "infected ticks do not produce infection during the first 2 days when feeding on cattle. Infected ticks are still infective after feeding upon a rabbit for 3 days. Heating infected ticks to 37° C. for 3 days does not render them infective during the first 2 days after they become attached to the host. The partial feeding of infected ticks for 2 days, followed by starvation for 17 days, renders them noninfective. Inoculations of emulsions of infective ticks collected from cattle on the fifth day of engorgement failed to produce infection. Infective ticks are rendered noninfective by exposure to a temperature of about 10° for 3 weeks. Their infectivity may be restored by subsequently warming them."

Piroplasmosis, G. H. F. NUTTALL (*Parasitology*, 6 (1913), No. 3, pp. 302-320, figs. 14; *Bul. Johns Hopkins Hosp.*, 24 (1913), No. 272, pp. 307-316, figs. 22).—This is a summarized account of the present knowledge of piroplasmosis.

Experimental investigations on the therapeutic action of yeast in alimentary, multiple polyneuritis in guinea pigs and pigeons, M. BARSICKOW (*Biochem. Ztschr.*, 48 (1913), No. 5, pp. 418-424, pl. 1).—Dried living yeast cells, zymine (acetone permanent yeast), Cerolin (an alcoholic extract of the fatty substances present in yeast), and a yeast killed by drying at 120° C. were used in these experiments. No difference was noted in the therapeutic effects between those preparations containing enzymes or living yeast cells and dead yeast cells which contain no enzymes. It is concluded that in all probability the therapeutic properties of yeast depend upon the nuclein or salts of nucleic acid which it contains.

Cultivation of the rabies organism, ANNA W. WILLIAMS (*Jour. Amer. Med. Assoc.*, 61 (1913), No. 17, pp. 1509-1511, figs. 2).—The author reports observations made during the course of studies of Negri bodies, in which attempts were made to cultivate the virus.

The parasite of rabies, O. BARTHOLOW (*Jour. Amer. Med. Assoc.*, 61 (1913), No. 17, pp. 1555, 1556).—A critical review of recent literature.

Note on rinderpest, E. W. OLIVER (*Dept. Land Rec. and Agr. United Prov. Agra and Oudh, Agr. Ser.*, 1913, *Bul.* 28, pp. 13, pl. 1, figs. 11).—A general description of this disease, including vernacular names for rinderpest as used in various parts of India, diagnosis, and treatment, based upon observations in India and South Africa.

The morphology of *Trypanosoma simiae* n. sp., D. BRUCE ET AL. (*Proc. Roy. Soc. [London]*, *Ser. B*, 85 (1912), No. B 581, pp. 477-481, pl. 1, figs. 3).—" *T. simiae* n. sp. is a well-defined species, easily separated by its morphology alone from the other trypanosomes which have been described as causing disease among domestic animals. It sets up a chronic disease in goats, but is chiefly remarkable for its rapidly fatal action on monkeys. In Nyasaland it is carried by *Glossina morsitans* and in this district, Central Angoniland, this tsetse fly is found to be heavily infected with this trypanosome."

Trypanosomes of the domestic animals in Nyasaland.—I, *Trypanosoma simiae* n. sp., II, III, D. BRUCE ET AL. (*Proc. Roy. Soc. [London]*, *Ser. B*, 87 (1913), No. B 592, pp. 48-57, 58-66, pls. 3).—Continuing the studies noted above, the authors find that as regards the susceptibility of various animals, *T. simiae* belongs to the same group as *T. peccorum*, and like the latter is erratic in its action. It affects goats, sheep, pigs, and monkeys, while oxen, antelope, dogs, rabbits, guinea pigs, and rats are practically immune. The reservoir of the virus is the warthog.

T. simia multiplies in the intestines and in the labial cavity of the proboscis of *Glossina morsitans*. Here only developmental forms are found, never infective forms. The *T. simia* growing in the intestines of the 'fly' has no specific characters by which it can be distinguished from other species of pathogenic trypanosomes found in tsetse flies. The final stage of the development takes place in the hypopharynx, wherein the infective form of the parasite, similar in shape to the trypanosome found in the blood of infected animals, is produced. The flies do not become infective until about 20 days after their first infected feed.

Trypanosome diseases of domestic animals in Nyasaland.—II, *Trypanosoma caprae*, D. BRUCE ET AL. (*Proc. Roy. Soc. [London], Ser. B*, 86 (1913), No. B 587, pp. 278-284, pl. 1, fig. 1).—" *T. caprae* belongs to the same group as *T. vivax* and *T. uniforme*, and affects the same animals, cattle, goats, and sheep. Monkeys, dogs, and the smaller laboratory animals are immune. The carrier is *Glossina morsitans*. The reservoir of the virus is the wild game living in the 'fly country.' "

The trypanosomes found in the blood of wild animals living in the sleeping sickness area, Nyasaland, D. BRUCE ET AL. (*Proc. Roy. Soc. [London], Ser. B*, 86 (1913), No. B 587, pp. 269-277).—" Thirty-one and seven-tenths per cent of the wild game in the 'fly country' below Kasu Hill harbor pathogenic trypanosomes. The species of trypanosomes found are *Trypanosoma brucei* vel *rhodesiense* 7.8 per cent, *T. pecorum* 14.4, *T. simia* 1.7, *T. caprae* 11.1, and *T. ingens* 1.7. It is self-evident that these wild animals should not be allowed to live in 'fly country,' where they constitute a standing danger to the native inhabitants and the domestic animals. . . . Active measures should be taken for their early and complete blotting out. . . .

"No pathogenic trypanosomes have up to the present been found by the commission in the blood of animals living in fly-free areas."

Morphology of various strains of the trypanosome causing disease in man in Nyasaland, D. BRUCE ET AL. (*Proc. Roy. Soc. [London], Ser. B*, 86 (1913), Nos. B 589, pp. 394-407, figs. 7; pp. 408-421, figs. 7; B 592, pp. 26-35, pls. 3, figs. 2).—The authors conclude that the 5 wild game strains resemble each other closely, and all belong to the same species of trypanosome (*Trypanosoma rhodesiense* (Stephens and Fantham).) The human strain differs to some extent, but also belongs to the same species. "There is some reason for the belief that *T. rhodesiense* and *T. brucei* (Plimmer and Bradford) are one and the same species."

"The trypanosome of the Mzimba strain is the same species as that occurring in the wild game inhabiting the Proclaimed Area, Nyasaland. It has already been concluded that this species is *Trypanosoma brucei* vel *rhodesiense*. Hence it would appear that wild *Glossina morsitans* occurring in a district 100 miles north of the Proclaimed Area are infected with the trypanosome which causes the human trypanosome disease of Nyasaland."

Studies on the biochemistry and chemotherapy of tuberculosis, IV, V, VI (*Jour. Infect. Diseases*, 12 (1913), Nos. 1, pp. 68-92; 2, pp. 249-275).—These parts continue previous work (E. S. R., 29, p. 177).

IV. Preliminary report of experiments in the vital staining of tubercles, Lydia M. DeWitt (pp. 68-92).—"Among the dyes so far tested, trypan blue, trypan red, isamin blue, pyrrhol blue, Ehrlich's rectified methylene blue, medicinal pure methylene blue, methylene blue of the U. S. Pharmacopœia, new methylene blue N, new methylene blue GG, and to some extent neutral red and pyronin have been found to penetrate tubercles in guinea pigs. Basic fuchsin, crystal violet, and the other new methylene blues are now being tested. . . .

"The dyes above mentioned are well borne for a long period if the dose of the methylene blues, basic fuchsin, and crystal violet is not too large. Almost any dose of the first 4 dyes mentioned is well borne. The individual bacillus itself is penetrated and well stained by all the methylene blues, by basic fuchsin, and crystal violet, by erythrosin and the eosins; not so well by trypan blue, trypan red, isamin blue, pyrrhol blue, pyronin, and neutral red. Methylene blue, Bismarck brown, and brilliant cresyl blue are the only dyes which have a possible bactericidal power over the organism, though many of the others seem to inhibit its growth in the test tube."

These experiments confirm von Linden's findings in so far that they demonstrate the possibilities of staining the tubercle bacillus in vitro, and also show that the dyes penetrate the tubercles in vivo. No stained tubercle bacilli were ever found in the tubercles or in tuberculous pus stained with dye.

V. *The behavior of the tubercle bacillus toward fat dyes*, Hope Sherman (pp. 249-273).—"All the dyes used, whether fat-soluble or not, stain pure cultures of tubercle bacillus, en masse, because of the presence of stainable substances outside the bacilli. Sudan III does not stain individual tubercle bacilli, either in smears of pure culture, in tuberculous pus, or in tuberculous tissue. Sudan yellow and Sudan brown stain the bacilli faintly, in pure culture smears, upon prolonged exposure, or on heating. Scarlet red resembles Sudan III in behavior, but is slightly less inefficient, about half the tests for individual staining being doubtful or even faintly positive.

"Nile blue sulphate gives a faint and rather unsatisfactory bacillus stain, as does Janus green, for the most part. A single smear stained with Janus green showed deeply stained bacilli, but this could not be duplicated. Indulin stains the bacilli faintly upon prolonged application. Indophenol blue does not show any bacillus stain. Dimethylaminoazobenzol gives a faint and unsatisfactory bacillus stain. Basic fuchsin, which is only slightly fat-soluble, eosin, and methylene blue, which are not fat-soluble, stain the individual bacilli deeply in a relatively short time.

"All the dyes used stained the impure ether extract of tubercle bacilli, while the purified ether extract was less readily stained by the majority of the dyes not classed as 'fat dyes.' The behavior of the dyes toward the impure ether extract corresponds with their behavior toward cultures of the bacilli, and is very different from that toward the individual bacilli. These facts seem to indicate that masses of ether-soluble substance exist on the surface of cultures as well as within the bacterial protoplasm, and it is with this extracellular material that the dyes combine. Basic fuchsin and eosin, and to a less extent Bismarck brown resemble the regular fat dyes in the ease with which they stain the ether extract. Dilute solutions of Nile blue sulphate and neutral red are more efficient than the saturated, in the staining of the ether extract. The fat dyes are not serviceable for the detection of tubercle bacilli in pus or in tissue, nor for their staining in pure cultures.

"Experiments with crushed bacilli confirm Benians' view that the acid-fastness of the tubercle bacillus depends upon the physical integrity of the bacterial cell. The fatty constituents of the tubercle bacillus are not, per se, the cause of the staining reaction characteristic of this organism."

VI. *Intra-vitam staining of tuberculous guinea pigs with fat-soluble dyes (supplementary note)*, H. J. Corper (pp. 274, 275).—"If indulin, dimethylaminoazobenzol (1 per cent in oil), and Bismarck brown (1 per cent in oil and water) are fed to tuberculous guinea pigs, they do not appear to enter the organs nor tuberculous areas to any appreciable extent when given for a period of about 65 days. Alkanin and annato, 1 per cent in oil, do not enter within a period of 14 days.

Contribution to the study of pulmonary tuberculosis induced experimentally by inhalation, V. GRYSZ and D. PETIT-DUTAILLIS (*Compt. Rend. Soc. Biol. [Paris]*, 73 (1912), No. 37, pp. 728-730; abs. in *Ztschr. Immunitätsf. u. Expt. Ther.*, II, Ref., 6 (1912), No. 12, pp. 927, 928).—In the experiments 73 guinea pigs were exposed in a specially constructed lead chamber to a spray of an emulsion of bovine tubercle bacilli. Twenty of the animals received one inhalation, and of these 19 died within 17 to 133 days. All showed well-disseminated, cheesy foci, and 3 cavern formations. A second group of animals received 2, 3, 4, 5, 6, 7, and 8 inhalations in from 2 to 36 hours. The guinea pigs which received 4 and 5 inhalations per day showed only slight sclerotic lesions, and almost one-half of the animals were free from tubercular changes.

In a third group where numerous inhalations were given at intervals of from 8 to 30 days, appreciable evidences of tuberculosis were present in all animals. Some of the animals died, others were killed.

New researches upon inhalation tuberculosis, P. CHAUSSÉ (*Bul. Soc. Cent. Méd. Vét.*, 89 (1912), No. 16, pp. 361-363).—This is a summary of a thesis submitted in competition for the Trasbot prize of 1912. See also previous notes (E. S. R., 26, pp. 179, 783).

Experimental pulmonary tuberculosis in the dog, P. A. LEWIS and C. M. MONTGOMERY (*Jour. Expt. Med.*, 17 (1913), No. 5, pp. 527-534, pl. 1).—Large quantities of tubercle bacilli of the bovine type introduced directly into the lungs by way of the air passages failed to reproduce a chronic pulmonary tuberculosis in the dog.

Milk-borne tuberculosis with special reference to impending preventive legislation, S. DELÉPINE (*Jour. State Med.*, 21 (1913), No. 6, pp. 336-363, figs. 2).—This is an extended article dealing with the improvement in the mortality from tuberculosis which has been effected in Manchester, England, by methods of inspection and inoculation. Results obtained in the course of 15 years are summarized as follows: "The proportion of tuberculous milk (as supplied to consumers) has been reduced to nearly one-third of the original amount. The number of farms with cows suffering from tuberculous mastitis has been reduced to nearly the same extent. The infectivity of the milk which still remains tuberculous has been reduced to a much greater extent. The proportion of cases of tuberculosis in children under 5 years of age has been reduced by one-half."

The author discusses pending legislation looking toward tuberculosis control and eradication.

Combating bovine tuberculosis with especial reference to the clinical and bacteriological diagnosis of the disease, R. VON OSTERTAG (*Die Bekämpfung der Tuberkulose des Rindes mit besonderer Berücksichtigung der klinischen und bakteriologischen Feststellung. Berlin, 1913, pp. XII+591, figs. 88; rev. in Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 17, p. 308).—The successive sections of this work take up the occurrence and distribution of the disease, the significance which it has from an economic and sanitary standpoint, and the necessity for combating the disease in bovines; investigations which have been conducted and the possibility of eradicating the disease; the significance of the various kinds of tuberculosis, i. e., open forms and nonoccult cases, for the distribution of the disease; clinical and bacteriological methods for diagnosing tuberculosis (with 88 illustrations); laws in regard to the control and eradication of tuberculosis in bovines; and various kinds of blanks which are used in the control of tuberculosis, official work in regard to tuberculosis, tariffs, etc.

The introduction and spread of the cattle tick (*Boophilus annulatus* var. *microplus*), and of the associated disease tick fever (babesiasis) in Austra-

lia, J. A. GILRUTH (*Proc. Roy. Soc. Victoria, n. ser., 25 (1912), No. 1, pp. 15-22*).—A historical account.

The hypodermic affection of cattle.—The ox warble, COPPENS (*Ann. Méd. Vét., 62 (1913), Nos. 6, pp. 309-328; 7, pp. 384-388*).—The first part of this paper relates to losses caused by this pest through its injury to the hide, flesh, etc.; the second part to its biology; and the third part to methods of control.

Bush sickness investigations, C. J. REAKES and B. C. ASTON (*Jour. Agr. [New Zeal.], 6 (1913), Nos. 4, pp. 399-401, fig. 1; 6, pp. 616-624, figs. 2*).—These reports relate to experiments in which various top dressings were applied to the soil and cattle and sheep then grazed upon the treated pastures. The best results were obtained in the case of cattle with soil dressings of (1) superphosphate, (2) sulphate of iron, (3) blood and bones, and (4) guano; in the case of sheep, with (1) sulphate of iron, (2) basic slag, and (3) superphosphate.

Vaccination against gangrenous mammitis in sheep and goats, J. BRIDRE (*Bul. Soc. Cent. Méd. Vét., 90 (1913), No. 8, pp. 184-187*).—This condition, with the vaccine originally used against it, has been previously discussed (E. S. R., 19, p. 1185). The work has now been continued for the purpose of obtaining a vaccine which will produce the smallest amount of lesions post-injection. Some tests with sheep are included, from which the conclusion is drawn that it is possible to obtain immunity against this condition by the treatment recommended.

Directions for using antihog cholera serum, J. F. MITCHELL (*California Sta. Circ. 106, pp. 3-14, figs. 6*).—A detailed account of the manner of immunizing hogs against hog cholera.

Virulent anthrax bacilli in the saliva of an affected horse, J. G. T. ABENTZ (*Berlin. Tierarztl. Wchnschr., 29 (1913), No. 36, p. 640; abs. in Vet. Rec., 26 (1913), No. 1317, p. 217*).—The author records the finding of virulent anthrax bacilli in the saliva of an affected horse showing considerable swelling of the throat. He thinks that transmission of the disease is possible by direct contact through the saliva.

The bacteriology and vaccine therapy of distemper in horses, W. LINTZ (*Jour. Expt. Med., 17 (1913), No. 5, pp. 511-516*).—Negative results were obtained in the attempt to immunize sick animals passively through the injection of serum from horses which had recovered from the disease. A vaccine consisting of 800,000,000 each of the pneumococcus and of the bacillus isolated, injected subcutaneously in the region of the neck, had a curative effect. An immunity conferred by vaccination with 50,000,000 of each organism apparently does not last longer than one year, though it lasts much longer if 3 inoculations are given at intervals of 3 days. By vaccinating affected as well as unaffected horses the following year the epidemic was promptly eradicated, not a single case proving fatal.

The diagnosis of dourine by complement fixation, J. R. MOHLER, A. EICH-HORN, and J. M. BUCK (*U. S. Dept. Agr., Jour. Agr. Research, 1 (1913), No. 2, pp. 99-107*).—Dourine, which is caused by *Trypanosoma equiperdum*, was first seen in the United States in 1886 and was noted at later periods in Nebraska, South Dakota, and Iowa, and in Montana in 1912. The disease when present in a chronic or latent form is difficult to diagnose, and a microscopic examination of the body fluids, etc., often fails to reveal the causative organism, although it may occasionally be found in the serous exudate of the plaques and also in the fluid obtained from the affected genital organs and in the edematous fluid obtained from the affected genital organs of stallions and mares. In Montana only a limited number of animals were clinically affected.

In view of the necessity for a ready means of diagnosis, the application of the complement fixation method has been attempted, using some diseased horses sent to the experiment station at Bethesda, Md. The problem of greatest difficulty has been the question of an appropriate antigen. "From time to time, as these animals died, certain tissues were obtained which it was suspected might furnish the desired results, but although shake extracts of the spleens, livers, kidneys, and bone marrow, as well as alcoholic and acetone preparations, were employed under various conditions, the results were rather discouraging."

From the literature it appears that the best results may be obtained from the use of suspensions of pure trypanosomes. "In place of the specific trypanosome of dourine being utilized, the writers selected the surra organism, as it had been previously ascertained by several investigators that the reaction obtained was not absolutely specific for any one trypanosome infection but was rather of a group nature." In a part of this work, instead of straight suspensions an antigen was made of the blood and macerated spleens of rats killed at the height of surra infection. The material was placed in a bottle containing glass beads, then shaken for 6 hours, filtered through gauze, and carbolic acid added to the filtrate.

The smallest quantity of serum from horses which gave a positive reaction was 0.05 cc., but the various comparative tests indicated that fixation in tubes containing 0.2 cc. of serum was sufficient for diagnostic purposes. The sera from normal animals, or those affected with diseases other than trypanosomiasis, did not react. As the method of preparing antigen described above did not later always give satisfactory results, antigen was prepared by drawing the blood of an infected dog into centrifuge tubes containing an equal amount of 1 per cent potassium citrate solution. The red blood corpuscles were cytolized with saponin, the mixture centrifuged, and the supernatant fluid drawn off. The opaque mass or residue after repeated washing with sodium chlorid solution was emulsified and titrated. This antigen proved very satisfactory with the blood from the horses in the Montana outbreak, but a more rapid method proved essential.

"Various organs from rats just dead from surra were tried out in both fresh and preserved states, and the results which were obtained from the fresh suspension of the macerated spleen of a rat just dead from surra were the most promising. . . . After repeated tests on horses clinically affected with dourine had shown the antigen to be uniformly constant in its action, the procedure of diagnosing dourine by this method was definitely adopted. . . .

"Gray or white rats are infected with surra by the injection of 0.2 cc. of blood from a rabbit infected with that disease. Since tests have to be made every day to keep up with the large number of cases submitted and as the antigen proves effective only when prepared fresh, it was arranged that at least 2 rats should die daily with the disease. When the rats appeared to be at the point of death late in the afternoon it was found that placing such rats in the ice chest until they died furnished a better antigen than when they have died in the cage during the night and have to be used the following morning. The spleens of the rats are removed, placed in a mortar, and ground up with a small amount of salt solution to a pulpy mass. From time to time more of the salt solution is added, and the suspension thus obtained is filtered twice through a double layer of gauze into a test tube. The quantity of the suspension from each spleen is made up to 40 cc. by dilution with salt solution. This suspension constitutes the antigen for the tests of the suspected dourine sera. . . . Occasionally the antigen does not prove satisfactory for the test

and has to be discarded. In these cases the fixation in all tubes is apparently due to the excessive amount of proteids from the spleen. Experience has shown that the excessively large spleens contribute such an antigen. . . .

"The test proper for the diagnosis of dourine is carried out in a manner similar to that practiced for the diagnosis of glanders [E. S. R., 25, p. 181]. . . . Since the testing has been undertaken by the method described, 8,657 samples have been examined from Montana and the Cheyenne and Standing Rock Indian Reservations in North Dakota and South Dakota. Of these 1,076 gave positive reactions, which appears to be a very large proportion, but when it is remembered that these animals were kept under range conditions without sanitary or veterinary control and also that before the disease was recognized as dourine it had been diagnosed for a long period as some other affection, it will be apparent that the opportunity for the spread of the disease was ideal. With the present system of diagnosis, by which even the latent cases can be determined, it is hoped to eradicate the disease quickly."

A bibliography is appended.

RURAL ENGINEERING.

Pumping plants, F. C. KELTON (*U. S. Geol. Survey, Water-Supply Paper 320, pp. 187-213, pl. 1*).—In cooperation with the Arizona Experiment Station, tests of 20 representative irrigation pumping plants in the Sulphur Spring Valley are reported, the object being to ascertain the initial cost, consumption, and cost of fuel, yield of wells, and general efficiency. All the plants tested were of the distillate centrifugal type, 18 being horizontal and 2 vertical pumps. The actual lifts varied from 18 to 73 ft. and the yields ranged from 69 to 1,080 gal. per minute. Of the pumps tested the rapid speed type appeared to be the more efficient.

The two causes which were preeminent in reducing the efficiency of the plants are said to be (1) the insufficient speed maintained by the pump, and (2) the improper timing of the engine ignition. Efficiencies ranging from 8.5 to 41.4 per cent were obtained.

The cost of pumping plants per rated horsepower varied from \$40 to \$104, exclusive of cost of well and buildings, with an average of \$66. The average cost per useful horsepower was \$290. The average fuel cost per acre foot of water pumped was \$4.39 with distillate at 16½ cts. per gallon in the northern part of the valley and 17½ cts. in the southern part, 5 per cent being allowed for losses by leakage and evaporation.

Details and design of headgates, B. A. ETCHEVERRY (*Jour. Electricity, 30 (1913), No. 11, pp. 248-251, figs. 7*).—This article deals with headgates and gate lifting machinery, describing the lever types, inclined plane types, pulley types, and a lever combined with inclined plane or gearing. The mathematical and mechanical principles of each are analyzed, and formulas for the design of the parts are derived.

Inverted siphon construction, B. A. ETCHEVERRY (*Jour. Electricity, 30 (1913), No. 25, pp. 578-581, figs. 5*).—This article calls attention to the necessary auxiliaries to inverted siphon construction, namely, wasteway and sand box, anchorage, air outlet and inlet valves, and blow-offs. It describes the details of the design and construction of several inverted siphons in use on private irrigation projects, on the Umatilla and Belle Fourche projects, and on irrigation projects in Spain. Special attention is called to different methods of reinforcing the siphon proper, to types of inlet and outlet, and to novel methods for draining away seepage water.

Land clearing, A. J. MCGUIRE (*Minnesota Sta. Bul. 134, pp. 32, figs. 22*).—The only practical methods of clearing land of stumps in use by farmers in northern Minnesota are said to be blasting and the use of the horsepower stump puller. The stump puller is considered most economical for small stumps, while for stumps so large that they can not be handled and burned when they are pulled, blasting is said to be best. "For very large stumps or green stumps the combined use of explosives and the stump puller gives the most satisfactory results." For the lowest cost and quickest results it is suggested that all trees and brush be removed at one time and a pasture or meadow established to keep down brush and bring returns. Green stumps over a foot in diameter should not be removed unless immediate cultivation is necessary as they may be removed more readily after a few years and the soil will be in a better condition. "When an explosive is used it should be placed under that part of the stump which will offer the greatest resistance, usually the center. The depth at which to place the explosive under the stump may generally be estimated by the diameter of the stump at the ground line."

"For removing stumps from clay or clay loam soil the lower grades of dynamite, 25, 27, and 30 per cent are quite equal to the higher and more expensive grades, 40 and 60 per cent. They are cheaper, less dangerous, and leave the soil in better condition." It is claimed that an explosive known as "virite" is being used successfully when the soil is not wet. It is said to be somewhat cheaper than dynamite, does not produce headache, and does not freeze. "A pound of explosive should be used for each foot of diameter of the stump, if it has been cut some time. From $1\frac{1}{2}$ to $1\frac{3}{4}$ lbs. per foot in diameter should be used for green stumps."

Dynamite is said to work best in wet soil when the earth is thoroughly tamped over, if care is taken not to tamp directly on the dynamite. Virite requires a soil free from water and must not be compressed at all as it will not explode, so that only the upper part of the hole should be thoroughly tamped.

The methods of priming, blasting, and firing charges are reviewed and warnings given as to the danger of improper procedure and carelessness. In this connection, it is suggested that before using dynamite methods of handling it be studied and that, if possible, an experienced man be employed for a day or two as an instructor.

Vitrified brick as a paving material for country roads, V. M. PEIRCE and C. H. MOOREFIELD (*U. S. Dept. Agr. Bul. 23, pp. 34, pls. 10, figs. 3*).—It is the purpose of this bulletin "to furnish information relating to the construction of brick roads and to supply suggestions for aiding engineers in preparing specifications under which such work may be satisfactorily performed."

The principal advantages of brick roads are stated as follows: (1) They are durable under heavy traffic conditions, (2) they afford easy traction and good foothold for horses, (3) they are easily maintained and kept clean, and (4) they present a very pleasing appearance. The principal disadvantage is the high first cost. One of the most essential features is stated to be the selection of the brick, and in this connection a brief discussion of raw materials and processes of manufacture, general physical characteristics of the perfect finished product, and field and laboratory tests is given.

In the construction of brick pavements or roads the essential features to be considered in preparing the subgrade are enumerated as (1) thorough drainage, (2) firmness, (3) uniformity in grade and cross section, and (4) adequate shoulders. Brick pavements should be supplied with strong durable curbs of stone, Portland cement concrete, or vitrified clay shapes, both on the sides and

at the ends. A firm unyielding foundation is a most essential feature, the proper type to be used depending largely on the material composing the subgrade and the character of traffic for which the road is designed. Where the traffic is comparatively heavy or where the material composing the subgrade is defective in any way a monolithic concrete foundation should be used. An adjustable cushion of fine sand, usually 2 in. in thickness, is necessary between the foundation and brick for correcting slight irregularities in the foundation. The brick should be laid on edge in uniform courses running at right angles to the line of the pavement, except at intersections, and joints should be broken. After laying, the pavement should be carefully inspected to detect defective brick. To smooth out all inequalities, it should be rolled in both directions with a power roller weighing from 3 to 5 tons. In order to keep the brick in proper position and protect the edges the joints should be filled, preferably with a Portland cement grout. Longitudinal expansion joints of some firm and durable bituminous material are deemed necessary next to the curb. The thickness of joint should vary with the width of the pavement, $\frac{1}{2}$ in. being suggested for roadways 20 ft. or less in width, $\frac{3}{4}$ in. for widths of 20 to 30 ft., 1 in. for widths of 30 to 40 ft., and $1\frac{1}{4}$ in. for greater widths.

With all materials considered delivered on the work and all costs expressed in cents the probable cost of constructing the brick pavement, including the subgrade, the 6 in. concrete foundation, curbs, etc., is estimated by the formula: Cost per square yard = $1.90 L + 0.213 C + 0.138 S + 0.157 A + 0.045 B$, in which C equals cost of cement per barrel, S cost of sand per cubic yard, A cost of coarse aggregate per cubic yard, B cost of paving brick per thousand, and L cost of labor per hour. Ten per cent should be added to allow for wear on tools and machinery and for unforeseen contingencies. Each inch subtracted or added to the thickness of foundation will make a corresponding difference of from 8 to 12 cts. in the cost per square yard.

Typical specifications for the construction of brick roads are presented, and a method for inspecting and testing paving brick is appended.

In conclusion the importance of proper engineering supervision is emphasized, and it is stated that since brick pavements are probably more expensive to construct than any other type of country road it is important that their construction should be carefully planned and well executed.

The production of sand and gravel in 1912, R. W. STONE (*U. S. Geol. Survey, Advance Chapter from Mineral Resources of the United States, Calendar Year 1912, pp. 18*).—Data are given showing the production of sand and gravel for various purposes in the various States during 1912. The total production is reported as 68,318,877 short tons, valued at \$23,081,555, a net increase in quantity of 1,471,918 short tons and in value of \$1,922,972 over the production of 1911.

Tests of the strength of cement (*Concrete-Cement Age, 2 (1913), No. 5, pp. 257, 258*).—In an abstract of a paper read by H. C. Johnson before the Concrete Institute at London are given the tabulated results of tests of 16 different brands of cement and mixtures thereof, conducted to emphasize the need of testing all materials, and comprising tests for tension, compression, binding, and effects of varying percentages of water. The author's conclusions are that a good strength in paste is no proper indication of a good strength in concrete; that the best tests of a cement's value for reenforced concrete or similar work are mortar compressions cured in water and in air; that any cement having a higher value in air than in water ought to be condemned; that not less than 22 per cent of water should be allowed in gaging paste and not less than 3 per cent plus $\frac{1}{2}$ the percentage as used in the paste in gaging mortar; that the standard of values for cement to be used in reenforced con-

crete work should be raised by 25 per cent; that a given strength of concrete should be specified instead of a given mix; and that cement should be sold by volume instead of weight and in paper bags containing 1 cu. ft.

Test of a kerosene oil engine, H. D. WILE (*Elect. World*, 62 (1913), No. 8, p. 389, fig. 1).—The engine tested resembles the ordinary 4-stroke-cycle, throttling-governor, stationary engine with mechanically operated valves and make and break ignition. A 7.5 K. W. generator was directly connected. The mixer, situated on top of the cylinder, supplies both water and fuel, which are atomized by the piston suction. Four series of tests were made as to jacket water temperature, time of ignition, amount of water in the cylinder, and economy run.

The most efficient jacket water temperature was found to be around 175° F. and the best angle of advance of ignition was 36, as compared with the average angle of 16° for gasoline engines. Water in the cylinder performs four duties, namely, prevents rapid explosions, excessive pressures, high temperatures, and the heavy deposit of carbon on the walls of the cylinder. Other points brought out are that the best ratio of kerosene to water in the mixer was as 3:1 and that the addition of more water decreased the thermal efficiency; that the percentage of heat absorbed by the jacket water was approximately 16 per cent; and that the heat lost in radiation and exhaust was approximately 55 per cent. The fuel economy was considered good, 0.872 lb. of kerosene per brake horsepower being the lowest consumption, which indicates that nonvolatile or low-grade fuels can be burned successfully in small units.

Comparison of cost of fuel for oil, gas, and steam engines and current for electric motor, W. A. KRITZER (*Gas Engine*, 15 (1913), No. 6, pp. 316, 317).—Several tables of data are given showing the cost of fuel per brake horsepower for 1 hour, for 24 hours, for 300 days of 10 hours each, and for 300 days of 24 hours each, using the maximum, average, and minimum prices for the fuel.

Wind power, VOGDT (*Deut. Landw. Presse*, 40 (1913), No. 49, pp. 590, 591, figs. 3).—The results of experiments with wind power indicate that the pressure of the wind on a wind motor per unit area increases with the square of the wind velocity, and the horsepower with the cube of the wind velocity, including skin friction. Under these conditions it is stated that the speed of a windmill wheel is directly proportional to the wind velocity. On this basis the following formula is suggested to determine approximately the available power of a windmill for certain wind velocities:
$$N = \frac{y \times F \times v^3}{150g}$$
. In this y equals the weight of 1 cubic meter of air in kilograms; F the average area in square meters of the windmill wheel at right angles to the direction of the wind; v the wind velocity in meters per second; and g 9.81 meters per second or the acceleration due to gravity. In this connection it is claimed that the efficiency of the wind power plants which have been tested vary between 65 and 80 per cent. The operations of several wind motors are described.

Electricity on the western farm (*Jour. Electricity*, 30 (1913), No. 25, pp. 576, 577).—This article gives operating data and rate schedules of several power companies supplying electrical power to farms throughout the Western States.

The rate schedules show a great difference in the methods of charging for power and the amount of the charge. The greatest demand for electrical power appears to be for irrigation pumping, so that the use of electricity in these cases is necessarily a seasonal use. It is concluded, therefore, that it is to the advantage of power companies to have the consumer make his installation small

and operate as many hours per day as possible in order to cut down the power company's plant investment and increase the return per unit of installed capacity.

Traction farming and traction engineering, J. H. STEPHENSON (*Chicago, 1913, pp. 330, figs. 151*).—This is a practical handbook for owners and operators of gasoline, alcohol, and kerosene engines on the farm, comprising descriptions of some of the makes of farm tractors with directions for their care and operation, and also two chapters by S. E. Brown on water supply and electric lighting systems for the farm. A section is devoted to threshing machines and the science of threshing. Chapters on the operation of gas and oil engines are as follows: The gasoline farm tractor, fuel consumption of gas engines, alcohol as fuel, kerosene as fuel for traction engines, balancing of engines, piston rings, valves, leaky pistons, the cylinder, the carbureter, modern ignition, vaporizing of fuel, cooling systems, lubrication, horsepower calculations, and gasoline engine troubles.

The care and repair of rubber belts, R. MOORE (*Power, 38 (1913), No. 4, pp. 145, 146, figs. 5*).—This illustrated article gives instructions for splicing and stitching rubber and canvas belts. The use of rubber belts on too small pulleys is not recommended, since the resulting inside compression and outside tension is likely to separate the plies. It is stated that animal fats and grease should never be used as dressing on rubber belts, but that boiled linseed oil is good, and also equal parts of black lead, red lead, French yellow, litharge, and enough Japan drier to make it dry quickly.

The construction of creameries, M. MORTENSEN and J. B. DAVIDSON (*Iowa Sta. Bul. 139, pts. 1, pp. 126-146, figs. 11; 2, pls. 21*).—Part 1 of this bulletin deals with the factors determining the success or failure of a local creamery, forms of organization, and data as to the location and construction of creameries as regards convenience, sanitation, heating, lighting and ventilation, and materials of construction. Eight typical creameries are described with specifications for their construction and bills of material. Part 2 gives building plans for these creameries.

Modern silo construction, J. B. DAVIDSON (*Iowa Sta. Bul. 141, pp. 159-229, figs. 63*).—This bulletin covers briefly the field of Bulletin 100 of the Iowa Station (E. S. R., 20, p. 687) and Bulletin 117 (E. S. R., 23, p. 590) and adds descriptions of several recent developments in silo construction, among which are the wooden hoop silo, pit silo, and the Iowa silo used as a water tower. In the last the silo walls are designed of sufficient strength to support a water tank for the general farm supply. The success of this method is to be reported in a later bulletin.

RURAL ECONOMICS.

A normal day's work for various farm operations, H. H. MOWRY (*U. S. Dept. Agr. Bul. 3, pp. 44*).—Notes and data based in part on personal observations and in part on replies to a circular of inquiry sent to 25,000 selected farmers as to the average or normal day's work for various farm operations are presented. Tables are given illustrating a normal day's work in using walking, sulky, and gang plows; plowing stubble and sod with a traction engine; using spike-tooth, spring-tooth, and disk harrows, a land roller, a grain drill, a broadcast seeder, knapsack sower, and wheelbarrow sower; in planting cotton, corn, sweet potatoes, Irish potatoes, cabbage, and tomatoes; cutting potatoes for seed and covering same after planting; making rows for planting; hauling and spreading manure with a spreader and by hand and

dumping manure in piles; cultivating corn, potatoes, beans, cabbage, and cotton; spraying an orchard; mowing, raking, tedding, and cocking hay; harvesting hay and corn with and without a binder; husking corn; digging potatoes; threshing grain; hauling to market with wagon; together with a number of other farm operations, giving the average work factors in terms of designated units per man, per horse, per hour, per day, etc.

Among the author's conclusions are the following:

"Daily and seasonal working factors for farm labor and equipment are of primary importance in farm organization and management.

"The seasonal and daily duty of men and equipment for an agricultural area can be reliably approximated by averaging many estimates for each operation made by farmers in the region. Figures so obtained are as accurate for practical purposes as those secured by more refined methods. . . .

"Those engaged in farming have quite definite conceptions of the duty for the simpler operations where but one or two men and one or two teams are involved. Where many men and units of equipment are used in an operation there is less definite conception of what constitutes a fair day's work, since fewer have had experience with the large crews, and the range of variation is greater. More data are therefore necessary to insure useful averages.

"With implements of heavy draft and also with many of the lighter implements, the increase in dimensions is not attended with proportional increases in work accomplished. . . .

"The increase in the number of men in the crew and in the complexity of the operation are attended by lost motion and decrease in efficiency per unit of labor and equipment. The simpler operations are the most economical from the standpoint of work done daily."

To work a grass holding at a living profit, and the cheap cottage problem, H. B. M. BUCHANAN (*London, 1910, pp. 102, figs. 3*).—This book discusses the problem of producing a hay crop, and the management of cows, pigs, and poultry on a small holding.

Land tenure in England and Norway, E. SUNDT (*Economist, 77 (1913), No. 3662, pp. 965, 966*).—This article discusses and illustrates the effect of feudalism upon agriculture and agricultural population, the author holding that the general exodus from the farm to towns and cities in England is due largely to the system of land tenure, particularly the entailing of property. Free trade in land is thus impossible, and the country is accordingly "doomed to a continuation of farming by tenants."

Irish agricultural laborers, 1912 (*Dept. Agr. and Tech. Instr. Ireland, Agr. Statis. 1912, pp. 45*).—This report submits notes and tables showing the number and earnings of Irish migratory agricultural laborers, the wages of agricultural laborers, and the number of persons engaged in farm work, together with the number and power of the various agricultural machines and implements in use in Ireland in 1912.

The total number of agricultural laborers is shown to have decreased from 509,344 in 1871 to 199,900 in 1911. There is also as much complaint among the farmers of the loss of efficiency of the laborers as of the difficulty in securing them.

The total number of persons engaged in farm work on June 1, 1912, is reported at 1,073,238.

Persons engaged in agricultural pursuits in Prussia, HAGMANN (*Mitt. Deut. Landw. Gesell., 28 (1913), No. 34, pp. 483-486*).—This article presents notes and tables showing observations made from the census of the agricultural

population of Prussia in 1907. The following table shows the number of persons engaged on different-sized farms:

Persons actively engaged in agriculture in Prussia.

Size of farm.	Kind of labor.			Number of persons per 100 hectares.
	Male.	Female.	Total.	
Under 2 hectares.....	747,559	1,846,911	2,594,470	259.5
2-5 hectares.....	673,416	824,383	1,497,799	87.7
5-20 hectares.....	1,273,995	1,244,343	2,518,338	43.4
20-100 hectares.....	754,476	620,171	1,374,647	20.9
100 hectares and over.....	602,992	432,278	1,035,270	17.5
Total.....	4,052,438	4,968,086	9,020,524	43.0

Other tables are given showing the number of persons engaged in agriculture in each Province or subdivision, also the kind of work in which they are engaged.

Population of rural districts in France. W. H. HUNT (*Daily Cons. and Trade Rpts.* [U. S.], 16 (1913), No. 210, pp. 1386, 1387).—This report shows that according to an inquiry made by the minister of agriculture the number of persons employed in agricultural pursuits in France decreased from 4,000,000 in 1862 to 3,000,000 in 1892 and to 2,320,000 in 1913, or a decrease of about 40 per cent in half a century. "Irregular work, long periods of enforced idleness, poverty resulting from bad harvests, frequent recurrence of certain calamities—hail, blight, mildew, etc.—induce them to abandon the soil and look elsewhere for better-paid work."

Data are given showing the working hours and farm wages for day laborers in different sections of the country.

Condition of Danish agriculture during 1911 (*Tidsskr. Landökonomi*, 1912, Nos. 7, pp. 434-463; 8, pp. 489-504; 9, pp. 537-553; 12, pp. 698-721; 13, pp. 761-778, 779-795).—The general condition of Danish agriculture in its various phases during the year 1911 is discussed in this volume by different specialists, as follows: Animal husbandry, by A. Appel; horse raising, by J. Jensen; crop production, by K. Hansen; Denmark's trade in agricultural products with foreign countries, by N. C. Christensen; dairy exports, 1911-1912, by B. Böggild; and meteorological conditions, 1911-12, by H. Hansen.

[Area, population, agricultural production, etc., in Canada, 1911-12] (*Canada Yearbook*, 1912, pp. 1-301).—This is an official publication giving in addition to other data a statistical census as to area, population, agricultural production, imports, exports, etc., of Canada for 1911-12 by Provinces and Territories, with comparison with former periods in a number of instances.

Tables showing the urban and rural population give for the whole country 3,280,964 of the former, an increase of 62.28 per cent over 1901; and 3,925,679 of the latter, an increase of 17.20 per cent during the same period. In the Provinces of Prince Edward Island, Nova Scotia, New Brunswick, and Ontario there has been an actual decline in the rural population since 1901, but a marked increase in the urban population.

The estimated total area under field crops in 1912 was 32,449,420 acres, yielding a harvest value of \$511,951,100. Tables are given showing the acreage, yield, value, etc., of the leading crops, together with data as to the production, value, etc., of butter and cheese in 1900, 1907, and 1910.

AGRICULTURAL EDUCATION.

Report of the temporary educational commission to the government and legislature of the State of North Dakota ([*Fargo, N. Dak.*], 1912, pp. 61).—This commission, organized in December, 1911, for the purpose of studying educational systems in the United States and elsewhere with a view to unifying and systematizing the educational system of North Dakota, outlines in this report the North Dakota educational system, what a state educational system should be, the bases of institutional organization, the scope of institutions, and the views of authorities concerning the function, control, and government of a state university.

Report of committee on agricultural education, T. E. FINEGAN (*N. Y. Dept. Agr. Bul.* 47, pp. 1253-1256, pl. 1).—This committee of the New York State Agricultural Society presents for the consideration of the society the report of the state advisory board, established in 1911 for the purpose of promoting and directing agricultural education and the advancement of country life. This report recommends "(1) that the main effort toward the introduction of agricultural education, whether through state or local aid, be directed toward the study of agricultural and rural subjects in the public high schools; (2) that in addition to those institutions already authorized to train teachers of agriculture, special and adequate provision be made for training such teachers at the State Normal College and in one or more normal schools; (3) that the state department of education give direction at a few points, distributed with reference to the leading agricultural industries, to the development of adequate teaching equipments in high schools which may serve as examples and illustrations for further extension of such equipment; (4) that the special state schools already established be developed toward teaching home economics and agricultural technology, the latter somewhat specialized for each school; (5) that the further development of the special state schools, when this may safely and wisely be accomplished, shall be made with reference chiefly to the fruit and vegetable growing interests, under which policy the southeastern and western parts of the State would be considered by the establishment of one school in each of those sections; and thereafter special schools of agriculture shall be established only if the people of a locality determine whether they desire a school and will take a substantial part in its financial support; (6) that this board favors legislation enabling cities of the first and second class to establish public schools of agriculture either within or without the limits of said cities; (7) that in schools of agriculture hereafter established, the commissioner of education, the commissioner of agriculture, and the director of the State College of Agriculture at Cornell University, shall be ex officio members of the boards of trustees."

Fourth annual report of the eleven district agricultural schools of Georgia, J. S. STEWART (*Bul. Ga. State Col. Agr.*, 1 (1913), No. 12, pp. 38, figs. 11).—Among the new features of work is the plan to give the girls some training in general agriculture as well as in care of poultry, milk, and vegetable and flower gardens, and the making of butter. The teachers' training course was taken by 53 students during the past year. It proved popular in 3 schools, and it is believed will soon become a valuable means of teacher training for rural schools. The complete course of study, which appears in the report, has again been revised.

Scientific farming on elaborate scale in the common schools, S. A. MINEAR (*Rural Educator*, 2 (1913), No. 2, p. 24, fig. 1).—According to this article there are over 4,000 schools in the State of Oklahoma teaching agriculture. About 3,500 are rural schools, all of which use agricultural text-books. Indoor experi-

mental work is carried on in 20 counties; object lessons in more than 16 counties; and school gardens, hotbeds, and outdoor experimental farms in more than 8 counties.

People's high schools in Denmark, C. G. RATHMANN (*School and Home Ed.*, 33 (1913), No. 2, pp. 51-54, figs. 3).—A brief statement concerning the establishment and objects of people's high schools in Denmark is followed by an outline of the daily program at the school at Wallekilde on the island of Zealand, which has an agricultural course.

The girls' agricultural school at Berlaer, C. C. PERVIER (*Nat. Stockman and Farmer*, 37 (1913), No. 18, p. 5, fig. 1).—A brief report is given on this Belgian school, which is solely for teaching practical and theoretical agriculture and dairying to farm girls and is under the supervision of nuns who also teach the girls household work of every kind. The girls do all the work of planting and harvesting on the 30-acre farm and of caring for the dairy herd. A 4-year course is offered, of which the fourth is devoted to agriculture. The government appropriates \$2,600 per annum for the school.

Methods in agricultural schools, D. SNEDDEN (*Jour. Ed. [Boston]*, 78 (1913), No. 1, p. 18).—Among the questions recommended to be discussed fully at the earliest moment are (1) to what extent should the agricultural school be preparatory to colleges in general or to the agricultural college; (2) what should be the character of the land used by the central school of agriculture; and (3) in what ways should the course of study admit of specialization? Each of these questions is here briefly considered.

The author maintains that 2 types of schools are practicable in Massachusetts, namely, the agricultural department of an existing high school and the central or county agricultural school. In the former case the agricultural training should be in the hands of one person giving his entire time to this work, and combining in his preparation scientific training with some experience as a practical farmer; (2) all the practical work of the boys should be done on home farms, the school attempting no farming; (3) the instructor should supervise the boys' practical work during the summer months with his vacation in the winter; and (4) each agricultural pupil may also take 1 or 2 studies of a general nature. In the case of the central or county agricultural school, there should be (1) a faculty of such a size as to justify its giving exclusive attention to agricultural (and, possibly, household arts) education; (2) two classes of pupils—those from farmers' homes and those from villages or the city; (3) sufficient land to give object lessons on a small scale of good farming and also to provide city boys with opportunity for practical work; and (4) a central location.

See also a previous note (E. S. R., 29, p. 191).

Problems in the administration and teaching of agriculture, G. A. BRICKER (*Texas School Jour.*, 30 (1913), No. 10, pp. 10-12).—This paper points out that instruction in agriculture should result in some immediate economic benefit and give the pupil an intelligent desire for farm life; should prepare the boy for continuing the agricultural work in the high school; and should be adapted to his nature and capacity. Attention is called to the importance of differentiating between agricultural nature study and elementary agriculture.

The redirection of the rural school, W. R. HART (*Rural Educator*, 2 (1913), Nos. 1, pp. 4, 5, 10, fig. 1; 2, pp. 18-20; 3, pp. 34-36).—This article discusses in a comprehensive way a number of psychological considerations entering into agricultural instruction, which the author believes increases the productive efficiency of education, aids in disciplining the mind, and satisfies to a large extent the demands of intellectual culture.

Agricultural training courses for employed teachers, E. R. JACKSON (*U. S. Dept. Agr. Bul.* 7, pp. 17).—In addition to a discussion of the means by which

employed teachers may acquire agricultural training, this bulletin contains lists of institutions maintaining courses in agriculture in summer sessions, institutions offering special short courses or extension courses in agriculture for teachers, correspondence and reading courses in agriculture, and a suggested reading course in agriculture based on Farmers' Bulletins and other free publications of this Department.

Subject matter in nature study and elementary agriculture (*Cornell Rural School Leaflet*, 7 (1913), No. 1, pp. 212, figs. 165).—This publication presents lists of subjects for 1913-14 in nature study and elementary agriculture as outlined in the New York State Syllabus. In addition to illustrative material for a special study of birds, animals, insects, plants, and trees, charts are given showing how a farm may be laid out and school grounds planted to trees, small shrubbery, etc.

Nature study and agriculture (*In Course of Study of the Elementary Schools of Oregon*. Salem, Oreg.: State Dept. of Ed., 1911, pp. 56-65).—This is an outline of the optional work in nature study in the first to the fourth grades, inclusive, and in agriculture in the seventh and eighth grades in one class.

Woodworking exercises for the agricultural school shop, H. B. WHITE (*Minnesota Sta. Bul.* 135, pp. 39, figs. 35).—The greater part of this bulletin consists of drawings and photographs showing the exact measurements of 30 exercises in carpentry work suitable for class work and not requiring the use of machinery. The descriptive matter is practically limited to lists and tabulated information.

Demonstration-lectures in domestic science (foods and cooking), sewing, and home nursing (*Ontario Dept. Agr. Bul.* 215, 1913, pp. 19, figs. 5).—Outlines of the courses are given, with a statement of some of the benefits derived from such work.

Sending the college to the State (*Mass. Agr. Col. Bul.*, 5 (1913), No. 5, pp. 16).—This pamphlet describes briefly the extension methods adopted by the Massachusetts Agricultural College, giving outlines of the various lines of work, with suggestions as to how individual farmers may secure special information.

MISCELLANEOUS.

Annual Report of Guam Station, 1912 (*Guam Sta. Rpt.* 1912, pp. 29, pls. 6, figs. 7).—This contains a summary of investigations by the special agent in charge, for the most part abstracted elsewhere in this issue.

Annual Report of West Virginia Station, 1912 (*West Virginia Sta. Rpt.* 1912, pp. 308, figs. 100).—This contains the organization list; a report of the director on the organization, work, and publications of the station, including a financial statement for the fiscal year ended June 30, 1912; departmental reports, the experimental work in which is for the most part abstracted elsewhere in this issue; reports to December 30, 1911, of work under state appropriations for the destruction of plant and insect pests and the promotion of the horticultural and trucking industries, portions of which are abstracted elsewhere in this issue; and reprints of Bulletins 135-137 and 139-141 and Circular 5 previously noted, and of Circulars 4 and 6 noted elsewhere in this issue.

A list of bulletins available for general distribution (*West Virginia Sta. Circ.* 4, pp. 2).

From the letter files of S. W. Johnson, edited by ELIZABETH A. OSBORNE (*New Haven, Conn.*, 1913, pp. 292, pls. 3).—Extracts from the letters and earlier writings of the former director of the Connecticut State Experiment Station, with a bibliography. Noticed editorially on page 1 of this issue.

NOTES.

Arkansas University and Station.—A 3 months' short course in agriculture has been established and opened with a good attendance. Domestic science courses have also been offered for the first time, more applicants being received than could be accommodated.

W. C. Thompson, assistant in animal husbandry, has resigned to become experimentalist in poultry husbandry at the New Jersey State Station and has been succeeded by D. H. Branson, animal husbandman at the Kansas College and Station. W. H. Wicks of the Idaho University and Station has accepted the position of horticulturist made vacant by the resignation of Ernest Walker, previously noted. L. H. Seymour, assistant in horticulture, has resigned to accept a commercial position.

Maryland College.—J. E. Metzger, a graduate of the Pennsylvania College and director of agriculture in the agricultural high school at Fergus Falls, Minn., has been appointed professor of agricultural education beginning January 1. He will begin his duties with a survey of the work now being done in the rural schools of the State in teaching agriculture and other vocational subjects. B. H. Darrow, a graduate of the Ohio State University and principal of the agricultural high school at Marion, Ohio, has been appointed Y. M. C. A. secretary, and in addition to his work at the college will make a survey of rural churches and do extension community work through the Y. M. C. A. and churches of the State.

Massachusetts College.—Associate professors Lockwood and Graham have been advanced to full professorships in dairy and poultry husbandry, respectively. E. M. McDonald has been promoted to the assistant professorship of agronomy.

Michigan College.—George R. Johnstone and Ford S. Prince, 1913 graduates of the University of Illinois, have been appointed instructors in botany and soils, respectively. F. A. Wilken, who has had charge of the substation at South Haven, resigned November 1, 1913.

Nebraska University and Station.—Frank C. Dean has been appointed agricultural editor beginning January 15.

Nevada University and Station.—Dr. P. B. Kennedy, who has had charge of the department of botany, horticulture, and forestry since 1900, resigned January 1 to become assistant professor in agronomy in the University of California. Dr. Maxwell Adams, professor of chemistry, has been granted a year's leave of absence for study in Europe.

North Dakota College and Station.—H. O. Werner has been appointed instructor in horticulture and assistant horticulturist.

Ohio State University and Station.—A census of the freshman boys shows that 56 per cent come from the farm, 39 occupations other than farming being represented, some of them in considerable numbers. Work on the new green-houses for which \$5,000 has been appropriated will be begun in the near future. Special attention is to be given to floriculture.

In the station, J. H. Muncie, assistant botanist, has accepted the position of assistant pathologist in the Michigan Station and has been succeeded by Richard C. Walton. W. M. Cook and M. O. Bugby of the department of cooperation have been detailed as acting county agents for Greene and Trumbull counties, respectively, with headquarters at Xenia and Warren.

Oregon College.—Schools of forestry and mines have been organized with George W. Peavy, formerly head of the department of forestry, and Henry Martin Parks, professor of mining, as the respective deans. G. D. Horton (M. S., Yale, 1913) has been appointed instructor in bacteriology.

The course in agriculture offered during Farmers' Week in December, 1913, attracted more than 600 farmers. Special attention was given to cooperative marketing and rural organization, addresses being given by experts in associated industries and by Dr. Hector Macpherson, the Oregon member of the American commission on European cooperative systems. More than 200 farmers and housewives registered for the short course beginning January 5.

Arrangements have been made by the extension director and the superintendent of the State Department of Education for cooperative management of the various district, county, and state school fairs. According to the revised plans for holding the fairs more emphasis will be placed on method and less on result. The exhibit system will be progressive, winners in the local fairs been eligible to make entries in the next higher fair. Exhibitors in the state fair will be given instruction in agricultural subjects and possibly provided with a summer camp while the fair is in progress.

Porto Rico College.—F. L. Stevens, dean of the college of agriculture and professor of vegetable pathology, has been appointed professor of plant pathology in the department of botany of the University of Illinois.

Washington College.—W. O. Ellis has been appointed instructor in entomology.

U. S. Department of Agriculture.—The investigations conducted for several years by the Dairy Division in soft cheese making at the Connecticut Storrs Station, on the ripening of Cheddar cheese at the Wisconsin Station, and on milk secretion at the Missouri Station, have been discontinued. Dr. Charles Thom, J. M. Currie, and K. J. Matheson are to continue the soft cheese work at Washington.

Miss A. C. Evans, assistant bacteriologist at the Wisconsin Station, and P. A. Wright, assistant chemist at the Missouri Station, have also been transferred to Washington, where they will undertake work in the bacteriology and chemistry of milk and its products along lines similar to those in which they were previously engaged.

Commission on Meat Supply.—A commission to investigate the economic causes of the present condition of the meat industry, with a view to suggesting possible methods of improvement, has been appointed by the Secretary of Agriculture. The personnel of the commission is as follows: Assistant Secretary B. T. Galloway, chairman; President H. J. Waters of Kansas; Dean C. F. Curtiss of Iowa; H. W. Mumford of Illinois; Dr. A. D. Melvin of the Bureau of Animal Industry; and Dr. T. N. Carver of the Rural Organization Service.

Sixth Graduate School of Agriculture.—Arrangements are being completed for the sixth session of the graduate school, which will be held at the University of Missouri June 29 to July 24. Dr. A. C. True, director of this Office, will again serve as dean, and the faculty will include leading scientists and experts from this Department, the agricultural colleges and experiment stations, and other universities, colleges, and scientific institutions in America and Europe.

Instruction will be offered under the following general heads: Genetics, agronomy, horticulture, animal husbandry, immunity and disease resistance in

plants and animals, and rural economics and sociology, including farm management.

The course in genetics, comprising 40 lectures and 12 seminars, will include a systematic presentation of the present status and outlook of the subject with special reference to its agricultural relations. The hours of this course will be so arranged that it will be open to all students.

The courses in agronomy and horticulture will deal mainly with special problems in the breeding and nutrition of field crops and orchard fruits respectively, and that in animal husbandry with breeding and nutrition with particular reference to beef and dairy cattle.

The course in immunity and disease resistance in plants and animals will include a résumé showing the present status of knowledge in these lines and the outlook for future investigations. In connection with this course, conferences of phytopathologists and veterinarians in separate groups are to be arranged on special problems in plant and animal diseases.

The course in rural economics and sociology, including farm management, will present a survey of the present status of these subjects and discussions of plans for their future development.

Special arrangements are to be made by which groups of students may study in some detail the methods, records, and equipment of the research work in progress at the Missouri University and Station. General principles regarding the organization and work of institutions for agricultural research and education will also be discussed in a series of conferences.

Correspondence relating to the membership in the school should be addressed to A. J. Meyer, Registrar, College of Agriculture, Columbia, Mo.

Society for the Promotion of Agricultural Science.—The thirty-fourth annual meeting of the society was held at Washington, November 11, 1913. Two joint sessions were held with the American Society of Agronomy, which met at the same time.

The address of the president, Dean E. Davenport, was on the subject, *How Will Extension Work React Upon Research?* The effect of the present popularity of demonstration and extension work on the popular mind, on appropriating bodies, on students, and on the standards of work was traced. This effect was felt to be such that "we may well feel solicitous for both the college and the station, especially for the latter, which can not hope to compete either in spectacular show or in immediate promise with its younger but robustious brother, the extension service." The responsibility was placed upon those in authority to "insist upon and to maintain at all cost a proper balance between real research and all other agencies for agricultural progress, however attractive, however expedient, however necessary."

In a paper on *Feeding Experiments to Determine the Availability of Protein*, B. L. Hartwell and R. A. Lichtenthaler reported work conducted with chickens in which beef scrap and cotton-seed meal were compared on the basis of the nitrogen recovered in analysis of the meat. The method brought out no important difference in availability of the two concentrates.

The Nutritive Values of Organic and Inorganic Phosphorus were considered in a paper by E. B. Forbes, based on an analysis of a large body of literature relating to work with various kinds of animals, and including some by the author with swine. A lack of harmony was found in the results with different kinds of animals, which could not be explained. The results were not thought to warrant final conclusions, but "the problem now seems to take the form of a question as to whether we shall regard organic phosphorus compounds as of superior nutritive value because of the chemical relationship of their phos-

phoric acid, or because of the presence of other unknown substances of value associated with them in natural foods."

The Theory of Antagonism of Salts and Its Significance in Soil Studies was presented by C. B. Lipman, who reported studies of the effect of certain combinations of alkali salts in barley cultures and upon soil organisms. Antagonisms were quite pronounced, which suggested the possibility of chemical means for alkali reclamation.

In a paper on The Relation of Ecology to Agriculture, L. H. Pammel presented an argument for the importance of such studies in connection with other lines of agricultural work.

Variation in the Tongue Color of Jersey Cattle was traced by Raymond Pearl, in a herdbook study of registrations made in 1893 and in 1913, twenty years apart. The results indicated "a simple case of Mendelian inheritance, in which pigmented tongue is the dominant character and nonpigmented the recessive."

F. W. Rane described What Massachusetts Has Accomplished for Science in Her Fight Against the Gipsy and Brown-tail Moths. This related to the importing and breeding of parasites and other natural enemies, the development of improved spraying machinery and insecticides, and forest management as a factor in moth control.

A paper on Factors of Efficiency in Farming, by W. J. Spillman, is to appear later as a Yearbook article.

The International Institute of Agriculture was described by A. C. True, who gave an account of the organization and operations of the institute, its general progress, and the fourth session of the General Assembly, held at Rome in May, 1913 (E. S. R., 29, p. 1).

Agricultural Education in Latin America was described by Clinton D. Smith, who recently served as director of the agricultural school at Piracicaba, Brazil. He gave accounts of the various agricultural schools in Brazil, and also in Uruguay, Argentina, Peru, and Chile.

The officers elected for the year were as follows: President, President H. J. Waters of Kansas; secretary-treasurer, Dr. E. W. Allen, Washington, D. C.; executive committee, Dr. H. P. Armsby, Dr. W. H. Jordan, and Dr. H. L. Russell; custodian and assistant custodian, Dr. W. J. Beal and Prof. W. D. Hurd, of Massachusetts.

American Association for the Advancement of Agricultural Teaching.—This association held its fourth annual meeting in Washington, November 11, 1913.

The opening topic was Home Project Work *v.* Laboratory and School Garden Plat Work for High School Students. C. G. Selvig of Crookston, Minn., held that the purpose of agricultural high schools is to train future farmers and to help farmers to become more efficient. The use of school land should, therefore, be to supply plats to landless pupils and to perform demonstrations for the benefit of the school and the community. An inquiry conducted by him indicated that the possibilities regarding the use of land at school and at home are barely beginning to be realized. W. R. Hart of the Massachusetts Agricultural College assigned a different function to the agricultural high school, maintaining that the work of the high school along agricultural lines should be cultural as well as vocational and that the home projects should be for cultural training as well as for economic purposes.

A. V. Storm of the University of Minnesota discussed the preparing of teachers of agriculture at the agricultural college through a special four-year course by special instructors, as compared with adding an elective of one year of pedagogics and practice teaching to the regular agricultural course. In his opinion, "in institutions where thorough preparation of teachers of agriculture

is the aim, most of the agricultural work should be taken in the regular courses, though by cooperation between the agricultural and pedagogical teacher a few special courses might be arranged, but even these should be taught by the agricultural specialist. The professional work should not be confined to one year but should be extended through the last two years with the privilege of taking some of it in the second year if the student desired. This professional work must include, among other things, the proper organization of the agricultural material into teachable form and practice in teaching it in that form. In institutions where only limited preparation can be made, either in summer sessions or regular term, a few of the most essential regular courses should be taken, but a larger number of specially arranged courses would be permissible here than under more favorable circumstances. These should be composite courses arranged cooperatively by the department of agricultural education and the particular agricultural department or departments concerned, but should be taught by the agricultural specialist."

In discussing this paper, G. A. Bricker of the Ohio State University suggested the offering of different amounts of technical agriculture, depending upon the character of the work to be undertaken by the teacher, this to be supplemented by pedagogical training by the department of agricultural education.

In discussing the preparation of extension and field men in the agricultural college, C. H. Tuck of Cornell University contended that in addition to strong courses in the various branches of agriculture, a department of expression should be maintained, the function of which should be to discover and to develop the men peculiarly fitted by nature for the extension service. G. I. Christie of Purdue University advocated providing some practical experience in extension work for the men while still pursuing their college courses.

The scope and purpose of agriculture in secondary schools was discussed by Director H. M. Loomis of the Smith Agricultural School at Northampton, Mass., who pointed out reasons for introducing agriculture into the public schools and offered suggestions relative to methods in secondary agriculture. He held that in teaching this subject no set scheme should be followed as yet, inasmuch as secondary agricultural instruction is in a state of progress and facts learned with regard to it should be verified. This paper was discussed by T. I. Mairs of the Pennsylvania State College, who maintained that agriculture in the course of study is justified by its relation to conservation, high cost of living, economics, and general culture, and that the teaching of agriculture in the high schools creates a sentiment in favor of the subject both in the school and the community.

The committee on the use of land in connection with agricultural teaching presented through C. G. Selvig a progress report dealing with the special agricultural school. R. W. Stimson reported upon the teaching of agriculture in the public high schools, and L. S. Ivins on the same topic in the elementary schools. F. W. Howe, of Syracuse University, presented a brief progress report on the cooperative use of equipment and illustrative material. The various committees were continued.

The officers elected for the ensuing year were R. W. Stimson, president; A. V. Storm, vice-president; and W. H. French, secretary-treasurer.

American Society of Animal Production.—This society, hitherto known as the American Society of Animal Nutrition, held its fifth annual meeting at Chicago, Ill., December 3, 1913.

E. B. Forbes presented a paper entitled Mineral Metabolism Experiments with Swine, in which he described the equipment and methods employed in metabolism experiments at the Ohio Station, and gave the results of investigations on the effect of water and mineral salts and on creatinin. F. G. King

reported experiments conducted at the Indiana Station on the value of grinding and shelling corn for hogs and compared results with those obtained at other stations. Feeding trials at the Kansas Station were reported by W. A. Cochel in which he outlined the methods of finishing cattle on roughage without grain supplements. J. M. Evvard gave the results of experiments which have been conducted at the Iowa Station on the value of different pasture crops for growing pigs and brood sows.

At the evening session the topic under discussion was the meat supply. After a brief statement of the importance of this subject by the president of the society, C. F. Curtiss, the discussion was opened by H. J. Waters, in which he spoke of the needs of readjusting the live stock industry, with particular emphasis upon the necessity for its redistribution. W. A. Cochel stated that more economical use of roughage and cattle feeding and an improvement of our waste lands were important factors toward increasing our meat supply. The changes taking place in the live stock industry were described by E. W. Morse of this Department and were shown to be similar to the changes going on in many other industries. He stated that much idle land in the East and South could soon be put to profitable use for meat production.

H. P. Armsby outlined the need of more scientific investigation in connection with fundamental problems in animal nutrition and showed wherein present-day experiments are more or less superficial. A study of the market conditions was reported by H. P. Smith in which he showed the constantly increasing number of calves slaughtered, particularly in the dairy States. J. H. Skinner pointed out the necessity of farmers in the Corn Belt putting live stock on a breeding basis, rather than remaining as "finishers" of range bred cattle. The possibilities of meat production in Central America were outlined by N. S. Mayo.

Several speakers referred to the proposed legislation prohibiting the slaughtering of calves under 1 year of age, their feeling being that such legislation was unnecessary, unjust, and difficult of enforcement if enacted. It was argued that the practice is actually an economical one, since the larger number of calves are slaughtered near the large centers of population where feed is too high to make into beef. Many of the calves are not of beef type, though they make good veal at 6 or 8 weeks of age.

There was a general agreement among all the speakers that the supply of meat in the United States had not been reached, as is supposed by many people. The present situation was criticised on the basis that the meat producer is not getting the profits he should, while the consumer is paying unusually high prices. It was believed that the present shortage in meat animals will be supplied as soon as production becomes more profitable. It was voted that the president appoint a committee to confer with the Secretary of Agriculture relative to plans for the study of the meat supply problem.

Officers of the society for the ensuing year were elected as follows: President, E. B. Forbes, Ohio; vice president, J. H. Skinner, Indiana; secretary and treasurer, D. H. Otis, Wisconsin; and the committee on experiments, H. W. Mumford, Illinois, and J. H. Skinner, Indiana.

Effect of kiln drying at 145° F. on the hop, Tartar and Pilkington.....	115
Expressed and distilled West Indian lime oils, Tempany and Greenhalgh....	116
Investigations on extraction of lime juice by milling, Tempany and Weil....	117
Experiments in lime juice concentration, Macintyre.....	117
Index to <i>Zeitschrift für Analytische Chemie</i> , Fresenius and Czapski.....	117

METEOROLOGY—WATER.

Temperature coefficients in plant geography and climatology, Livingston.....	117
British rainfall, 1912, Mill and Salter.....	118
Evaporation from a plain water surface, Leather.....	118
Dew ponds and mist ponds, Martin.....	118
Artesian water supply of eastern and southern Florida, Sellards and Gunter....	119
Report of the interstate conference on artesian water, Sydney, 1912.....	119

SOILS—FERTILIZERS.

Soil, soil investigation, and soil valuation, Pilz.....	119
Chemistry, physics, biology, and cultivation of the soil, Hoffmann.....	119
Contribution to the study of the soils of the Republic of Argentina, Lavenir...	119
Soil culture in Iceland, Gruner.....	119
The results of mixed cultivation with loam in Finland, Rindell.....	119
Moor culture, Kostlan.....	120
The shrinking of swamp soils resulting from drainage and cultivation, Tacke..	120
The influence of plant roots on the structure of the soil, Berkmann.....	120
The influence of subsoil loosening on soil yield, Augustin.....	121
The minimum water capacity of soils and its cause, Moskovie.....	121
The reaction of aqueous extracts of soils, Saidel.....	121
Alkaline reactions caused by acids and their acid salts in soils, Masoni.....	122
The chemistry of humus, with special reference to soil and plant, Jodidi.....	122
The nature of humus and its relation to plant life, Jodidi.....	122
The influence of plant covering on soil temperatures, Frödin.....	122
The use of dialysis and oxidizing power in judging soils, König et al.....	123
Dialysis and power of oxidation in the judgment of soils, König.....	124
The soil solution and the mineral constituents of the soil, Hall et al.....	124
Ten years' experiments on the action of fallow, manure, and clover, Koch.....	124
Soil hygiene and green manuring, Arndt.....	125
Report of the agriculturist, Gaskill.....	125
The management of solid and liquid manures, Ringelmann.....	125
Enrichment of farmyard manure by cake feeding, Hall.....	125
Tests of nitrogen on sandy and upland moor soils, Tacke and Brüne.....	125
The lime-nitrogen industry, Siebner.....	125
Nitrogenous fertilizers obtainable in the United States, Turrentine.....	126
Replacement of potash in feldspathic rocks by fertilizers, André.....	126
Investigations on the composition of Thomas slag, Popp.....	126
Steamed and unsteamed bone superphosphate and Thomas slag, Schulze.....	126
The use of raw phosphate and siliceous lime as fertilizers, Pfeiffer.....	127
Agricultural value of carbonate of lime from causticizing plant, Hendrick....	127
The action of quicklime on the soil, Hutchinson.....	127
Mineral and nitrogen contents of pine needles and straw, Bauer.....	127
Tobacco stalks as a fertilizer, Haskins.....	127
Chemical industries of Belgium, Netherlands, Norway, and Sweden, Norton..	127
Report of the fertilizer section, Haskins.....	128

AGRICULTURAL BOTANY.

The action of certain nutrient and nonnutrient bases on plant growth, McCool..	128
Application of fertilizers to plants through their leaves, Larue.....	128
Saponins as a source of carbohydrates for vegetation, Solacolu.....	129
Distribution of asparagin, glutamin, arginin, and allantoin in plants, Stieger..	129
Formation of anthocyan pigments of plants, VI, Keeble, Armstrong, and Jones..	129
Synthesis by sunlight in relationship to the origin of life, Moore and Webster..	129
Hemicelluloses in roots, rhizomes, and tubers, Stieger.....	130

Contractions resembling plasmolysis caused by pure distilled water, Osterhout..	130
Toxic inorganic salts and acids as affecting plant growth, Lipman and Wilson..	130
Arsenic compounds in agriculture and possible danger, Ampola and Tommasi..	130
Anatomical and physiological influence of tobacco smoke on seedlings, Purkyt..	131
Injuries to vegetation by furnace gases and ashes, Müller et al.....	131
Effects of illuminating gas on vegetation, Stone.....	131
Influence of radio-active body on germination, Crochetelle.....	131
Semipermeability of seed coats, Shull.....	132
Influence of partial suppression of the reserve material in seeds, Delassus.....	132
The function of grape leaves in relation to the clusters, Marescalchi.....	132
Some points on the floral development of red clover, Martin.....	132
Demonstrations of ectotrophic and endotrophic mycorrhiza, McDougall.....	132
Contributions on the colorless sulphur bacteria, Hinze.....	133
Culture of micro-organisms, Küster.....	133

FIELD CROPS.

Causes of the increased yields during the last three decades, Lehn.....	133
Making money on farm crops, Nichols.....	133
[Experiments with field crops].....	133
Field experiments.....	133
[Field crop experiments], Foulkes.....	134
Manurial experiments, Balfour and Rushton.....	134
Report of the Hedemarken Experiment Station, 1912, Christie.....	134
Report of Ribe County Western Agricultural Society, 1912, Esbjerg.....	134
Report of the plant culture stations, 1912-13, Larsen et al.....	134
Plant breeding at Tystofte, Lindhard.....	134
A method for variety tests, Bilger.....	134
The influence of vegetative factors on yield, Mitscherlich and Floess.....	135
Cereal investigations at the Nephi [Utah] substation, Cardon.....	135
Prevention of lodging of cereals, Ziehe.....	136
Influence of moisture, fertilizer, and soil on barley and wheat, Polle.....	136
Composition of timothy and wheat plants during growth and ripening, Haigh..	137
[Fibers from Papua (British New Guinea) and India].....	138
The use of sulphur in the cultivation of turnips and beets, Magnien.....	138
Bean growing in eastern Washington and Oregon, and northern Idaho, Fluharty	138
Field trials on the manuring of carrots, Stokes.....	138
Clovers, Calvino.....	138
Crimson clover, Grantham.....	138
Effect of frost on corn, Lindsey.....	138
Seed selection of Egyptian cotton, Kearney.....	138
Propagating cotton plants by slips, Gastet.....	139
Cowpeas for soil improvement, Grantham.....	139
Value of meadow foxtail grown on peat soils, von Feilitzen et al.....	139
A variety test of potatoes, Gaskill.....	139
[Field crop experiments], Malthouse.....	139
Sulphur for prevention of scab and as indirect fertilizer, von Feilitzen.....	139
Lessons for American potato growers from German experiences, Orton.....	139
Beet sugar in New England, Lindsey.....	140
Sugar-cane experiments, Harrison and Ward.....	140
Classification of the forms of <i>Helianthus annuus</i> , Sazyperow.....	140
Research work at Harrow Experimental Station, 1911, Barnett.....	140
Tobacco culture, Blackshaw.....	140
Cultivation of tobacco for the preparation of fruit and hop washes.....	140
A cross between <i>Triticum vulgare</i> and <i>T. monococcum</i> , Wawiloff.....	140
Wheat growing in Wisconsin, Delwiche and Leith.....	141
Some variable results of seed testing, Stone.....	141
Seed work for the year 1912, Stone.....	141
"Yellow rattle," as a weed on arable land, Brenchley.....	141

HORTICULTURE.

Intensive farming, Corbett.....	141
Recent progress in Belgian horticulture, Vernieuwe.....	141
Malnutrition or overfertilization of greenhouse crops, Haskins.....	141
Influence of light, soil moisture, and hydrocyanic-acid gas on cucumbers, Stone..	142
Effects of fertilizers on growth and composition of asparagus roots, Morse.....	142

	Page.
The inheritance of blossom color in beans, Shaw.....	142
Report of cranberry substation for 1912, Franklin.....	142
New varieties of fruits, Nombrot.....	143
Crew work, costs, and returns in orcharding in West Virginia, Arnold.....	144
Cultivation and exploitation of the avocado, Valencia.....	144
Mulberry and fig culture, Calvino.....	144
On some hybrids of <i>Vitis vinifera</i> and <i>V. berlandieri</i> , Gard.....	144
On the use of seedling vines as scions, Trabut.....	144
The reconstruction of vineyards without grafting, Oberlin.....	145
Some new or little-known Philippine economics, Barrett.....	145
The Kafir orange, Fairchild.....	145
American medicinal flowers, fruits, and seeds, Henkel.....	145
Experiments in bulb growing at Bellingham, Dorsett.....	145
Weed extermination, Stone.....	146
Legislation against diseases and pests of cultivated plants in Ceylon, Petch....	146

FORESTRY.

Forest valuation, Riebel.....	146
An economic study of acacias, Shinn.....	146
Manihot caoutchouc, Zimmermann.....	146
Device for planting white pine seed, Stone.....	146
Experimental telegraph poles after eight years' service, Teesdale.....	146

DISEASES OF PLANTS.

Topics covered by department of vegetable physiology and pathology, Stone....	147
Diseases more or less common during the year, Stone.....	147
Work of the botanical research laboratory at Klosterneuburg, Linsbauer et al..	147
Studies of plant diseases, Müller, Molz, and Morgenthaler.....	148
Notes on <i>Cronartium coleosporioides</i> and <i>C. filamentosum</i> , Meinecke.....	148
Mosaic and allied diseases in tobacco and tomatoes, Chapman.....	148
Cucumber and tomato canker.....	148
White-heads or take-all of wheat and oats.....	148
The barberry and its relation to black rust of grain, Güssow.....	149
Action of luminous radiations on conidia on <i>Botrytis cinerea</i> , Moreau.....	149
A bacterial rot of cucumbers, Burger.....	149
Corynespora leaf spot of cucumbers, Grosser.....	149
Fusarium or Verticillium on okra in North Carolina? Wilson.....	149
Black heart of potatoes, Bartholomew.....	149
Experiments relating to the control of potato scab, Stone and Chapman.....	150
Relation of cane cultivation to the control of fungus diseases, Johnston.....	150
The black rots of the sweet potato, Taubenhaus.....	150
Recent diseases of grapevines, their importance and treatment, De Zúñiga.....	150
Downy mildew in Vacluse in 1913, Zacharewicz.....	150
Mildew in 1913, Cadoret.....	151
A Botrytis disease of dahlias, Cook and Schwarze.....	151
Some fungus diseases of trees, Pammel.....	151
Shade tree troubles, Stone.....	151
Chestnut blight, Stone.....	151
The blights of coniferous nursery stock, Hartley.....	151
Herpotrichia and Neopectia on conifers, Sturgis.....	152
A new rust, Stone.....	152
Spotting of rubber on the plantation, Cayla.....	152
An investigation of lime-sulphur injury, its causes and prevention, Safró.....	152
Spreading capacity and adherence of sprays, Vermorel and Dantony.....	153
Preparation of alkaline sprays, Vermorel and Dantony.....	153

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Game protection and propagation in America, Chase.....	153
Game law blue book, Reynolds.....	153
Rats and their extermination, Daley.....	153
Rat proofing a municipal sewer system, Simpson.....	153
A history of the game birds of Massachusetts and adjacent States, Forbush....	153
Insect porters of bacterial infections, Martin.....	153

	Page.
Insect record for 1912 in Massachusetts, Fernald.....	153
Insect fauna of the soil near Manchester, Cameron.....	154
Phytopathological report for the year 1912, Marchal.....	154
Report of the entomologist, Ballard.....	154
List of insect pests, Morstatt.....	154
[Cranberry insects in 1912], Franklin.....	154
Methods of controlling mill and stored grain insects, Dean.....	155
The destruction of injurious insects by vegetable parasites, Le Moul't.....	155
Tests of insecticides, Fernald.....	156
The common house roach as a carrier of disease, Longfellow.....	156
Occurrence of the woolly aphis in the core of apples, Hewitt.....	156
Peach aphis investigations during winter and spring, 1912, Hardenberg.....	156
The San José scale in Tennessee with methods for its control, Bentley.....	157
Preliminary notes on a scale insect infesting the banana in Fiji, Jepson.....	157
The Abutilon moth (<i>Cosmophila erosa</i>), Chittenden.....	157
The red-humped caterpillar (<i>Schizura concinna</i>), Vosler.....	157
The fruit-tree leaf roller (<i>Archips argyrospila</i>), Weldon.....	157
A new sugar-cane pest, Fuller.....	157
The Hessian fly, Headlee and Parker.....	157
The red clover gall gnat (<i>Amblyspatha ormerodi</i> n. sp.), MacDougall.....	159
A jumping maggot in cactus blooms (<i>Acucula saltans</i> n. g. and n. sp.), Townsend.....	159
Mosquito extermination and its problems, Winship.....	159
The natural host of <i>Phlebotomus minutus</i> , Howlett.....	159
Recent literature on sand flies, Friederichs.....	159
Control measures for use against flies, Vaillard.....	159
The distance flies may travel over water, Hodge.....	159
An unusual outbreak of <i>Stomoxys calcitrans</i> following floods, Fuller.....	160
The maggot fly pest in sheep, Major.....	160
The bean stem maggot, Jack.....	160
Experiments for the control of the onion maggot, Fernald and Bourne.....	160
The manzanite Serica (<i>Serica anthracina</i>), Essig.....	160
The Halticini attacking Cruciferae in central Europe, Heikertinger.....	160
The destructive Eleodes (<i>Eleodes omisssa borealis</i>), Essig.....	161
The fruit tree bark beetle (<i>Scolytus rugulosus</i>), Essig.....	161
<i>Xyleborus</i> (<i>Anisandrus</i>) <i>dispar</i> and its food fungus, Schneider-Orelli.....	161
A billbug injurious to small grain (<i>Sphenophorus discolor</i>), Smith.....	161
Black brood in bees, Serbinow.....	161
A chalcidid which parasitizes <i>Ceratitis</i> and <i>Dacus</i> in West Africa, Silvestri.....	161
A new braconid of the genus <i>Microdus</i> from Canada, Richardson, jr.....	161
The enemies of plant pests: The Aphelininae, Mercet.....	161
Collembola damaging pine trees, Collinge.....	161
The use of sheep in eradication of Rocky Mountain spotted fever tick, Wood.....	162

FOODS—HUMAN NUTRITION.

Bouillon cubes compared with meat extracts and homemade preparations, Cook.....	162
Bouillon cubes, Cook.....	163
Notes on rare fishes sold for food in east London, Stubbs.....	163
Determination of the sanitary quality of shell oysters, Smith.....	163
Studies of phosphatids, particularly those in egg yolk, Eppler.....	163
The gluten content of flour, Budai (Bauer).....	164
The activity of the amylolytic enzymes in wheat flour, Swanson and Calvin.....	164
Some points in the making and judging of bread, Bevier.....	164
A new method for keeping bread fresh, and its significance to bakers, Katz.....	164
The grinding of corn meal for bread, Dunnington.....	165
[Banana recipes], Barrett.....	165
Hickory nuts and hickory nut oil, Peterson and Bailey.....	165
[Analyses of food, beverages, and drugs], Hanson.....	165
Food and drug and weight and measures laws of Nevada, with regulations.....	165
Wisconsin dairy and food laws and decisions of courts, Emery.....	165
A study of use of ice and other means of preserving food in homes, Williams.....	165
Cooking and heating with electricity, Phillips.....	166
The food factor in some sociologic problems.....	166
[Increased cost of maintenance of children].....	166
Cost of living in Nova Scotia, Ragsdale.....	166
Food prices in London as affecting the poorer classes, Pringle.....	166

	Page.
[Luncheon for women clerks employed in the Bank of England], Harvey	166
[Dietaries and accounts for Poor Law Unions, England and Wales].....	167
Diet social service in dispensary work, Klaer.....	167
A food clinic.....	167
Report on bacterial food poisoning and food infections, Savage	167
Relation of diets and castration to transmissible tumors, Sweet et al.....	167
Mixed diet and metabolism.....	168
The mineral content of the daily diet, Hornemann.....	168
The normal presence of boron in animals, Bertrand and Agulhon.....	168
The presence of boron in animals, Bertrand and Agulhon.....	168
The presence of boron in milk and eggs, Bertrand and Agulhon.....	168
Metabolism after meat feeding of dogs, Benedict and Pratt.....	168
Metabolism in connection with an experimental march, Melville et al.....	169
Experimental marches for deciding a scale of field service rations.....	169

ANIMAL PRODUCTION.

Commercial feeding stuffs, Jones, jr., et al.....	169
Use of the bitter acorn in the feeding of domestic animals, Courbet.....	169
Rations for farm stock.....	169
On the question of the nitrogen retention from the feeding of urea, Grafe.....	169
Nutrition of the embryonic chick, I, II, III, Bywaters and Roue.....	170
A respiration apparatus for sheep and swine, Tangl.....	170
Twenty-five years of German animal production, Hansen.....	170
Methods of cattle raising and management under modern intensive farming...	170
Treatise on zootechny.—III, The bovine, Dechambre.....	170
Breeding cattle in French Guinea, Aldigé.....	171
Breeds, breeding, and utility value of cattle of Dutch East Africa, Lichtenheld..	171
The Creole cattle of Salta, García.....	171
On beef production [in Argentina], Lahitte.....	171
The frozen meat industry of Argentina, Bergés.....	171
Foreign meat in London, Loop.....	171
The shrinkage in weight of beef cattle in transit, Ward and Downing.....	171
Sheep farming in North America, Craig.....	173
Boulonnaise breed of sheep, Tribondeau.....	173
Fitting yearling wethers and lambs for exhibition, Humphrey and Kleinheinz..	173
Cassava for pigs, Frateur and Molhant.....	174
Trials with weights of fattening swine and the "plucks" from these, Holm....	174
Treatise on zootechny.—II, The horse, Dechambre.....	174
Did the horse exist in America at the time of discovery, Trouessart.....	174
The feeding of farm horses.....	174
Horse feeding experiments with dried beer yeast, von Czadek.....	175
Cotton-seed meal as a feed for laying hens, Morrison.....	175
Poultry notes, 1911-1913, Pearl.....	175
Mardi Gras poultry in France, Brown.....	175
Breeders' and cockers' guide, Glover.....	175
The national standard squab book, Rice.....	175

DAIRY FARMING—DAIRYING.

Some practical results of feeding experiments, Lindsey.....	175
The food value of plain and molasses beet pulp, Lindsey.....	176
The value of oats for milk production, Lindsey.....	176
Feeding experiments with milch cows, Carlier.....	176
Niger cake for milch cows, Warsage.....	176
Feeding experiments with hay and varying amounts of protein feeds, De Vries..	177
North Carolina dairy herd records, Eaton.....	177
Report of the Richmond-Lewiston Cow Testing Association, Carroll.....	177
Dairy industry in northern Europe, Guittonneau.....	177
Report of the sanitary inspector of the State of Idaho, 1911-12, Wallis.....	177
Report of the feed and dairy section, Smith.....	178
The ductal system of the milk glands of the bovine, Wirz.....	178
[Factors affecting the composition of milk], Aurousseau and Ponscarne.....	178
The viscosity of cream, Dumaesq.....	179
Influence of factory methods on water content of Edam cheese, Van Dam.....	179
On the faulty "Knijpers" in Edam cheese, Boekhout.....	179

	Page.
Wensleydale cheese, Davies.....	179
Some investigations of parchment paper, Hals and Heggenhaugen.....	179

VETERINARY MEDICINE.

Report of civil veterinary department, Eastern Bengal and Assam, Harris.....	180
Report of civil veterinary department, Assam, 1912-13, Hickey.....	180
The diagnosis of newly lactating animals according to Schern's method, Weber.....	180
Use of pituitary extract in bovine and equine obstetrics, Schmidt and Kopp.....	180
Serum-therapy in practice, Menary.....	180
Natural variation of <i>Bacillus acidilactici</i> , Arkwright.....	180
The action of the protein poison on dogs: A study in anaphylaxis, Edmunds.....	180
Specificity and diagnostic value of Ascoli thermoprecipitin reaction, Finzi.....	180
Thermoprecipitation in anthrax, Szymanowski and Zagaja.....	181
Anthrax vaccination, its use and abuse, Goodwin.....	181
Feeding experiments with the virus of infectious bulbar paralysis, von Rátz.....	181
Relationship between paratyphoid infections in man and in animals, De Jong.....	181
Some peculiar bodies in erythrocytes in rinderpest, Braddon et al.....	181
A supposed neutralization of tetanus toxin by neurin or betain, Adersen.....	182
"Tick paralysis" following bites of <i>Dermacentor venustus</i> , Hadwen.....	182
Experimental "tick paralysis" in the dog, Hadwen and Nuttall.....	182
The chemistry of tuberculin, Lockemann.....	182
The chemistry of the tubercle bacillus.—A preliminary report, Löwenstein.....	182
The inhalation of tuberculous material from man by the cat, Chaussé.....	183
Cases of spontaneous tuberculosis caused by avian tubercle bacillus, Cobbett.....	183
Subcutaneous tuberculosis in bovines, Pérard and Ramon.....	183
Specific action of serum by mixing tuberculin and tuberculosis serum, Sata.....	183
Passive transference of tuberculin sensitiveness by tuberculosis serum, Sata.....	183
Specific action of tuberculosis serum with anaphylatoxin tests, Sata.....	183
The urochromogen reaction as an indicator for tuberculin treatment, Weisz.....	184
The precipitation method for diagnosing contagious abortion, Szymanowski.....	184
Infectious abortion in cattle, and its control by vaccination, Schreiber.....	184
Methylene blue, a remedy for infectious abortion, Rich.....	184
Generalized mycosis in the bovine, Langrand.....	185
The keeping quality of antihog cholera serum, Barok.....	185
A disease (salmonellosis porcina) in pigs, Lignières.....	185
An enzootic among young pigs caused by <i>Streptococcus pyogenes</i> , Rievel.....	185
Injury to fetlock with purulent infection—autotherapy, MacDonald.....	185
Fistulous withers, and synovitis of coronary joint—autotherapy, Mackeller.....	185
Virus carriers of influenza of the horse, Bergman.....	185
Etiology and therapy of typhoid fever or influenza in the horse, Bemelmans.....	186
Influenza among remounts and its treatment with salvarsan, Jäger.....	186
A note upon strangles in the Philippine Islands, Boynton.....	186
Protective substance of fowl cholera immune serum, Weil.....	186
The rapid cure of polyneuritis gallinarum, Wellman et al.....	187

RURAL ENGINEERING.

Irrigation branch.....	187
Irrigation of Santa Cruz Valley, Hinderlider.....	187
Pressure pipes for conveyance of water and for inverted siphons, Etchevery.....	187
The economics of pipe line diameters.....	188
Light-iron irrigation flume.....	188
Heavy oil as fuel for internal combustion engines, Allen.....	188
Naphthalin for gas engines.....	189
The naphthalin motor, Haenssger.....	190
Connecting electric motors for direct drive, Mills.....	190
Installation and care of storage batteries, Nichols.....	190
The Winnipeg tractor trials, Ellis.....	190
Mechanical cultivation in Germany, Bornemann and Donáth.....	191
Various devices for drying the autumn forage harvest, Rahm.....	191

RURAL ECONOMICS.

Cooperation and nationality, Russell.....	191
The legal status of farmers' cooperative associations.....	191
Agrarian reforms and the evolution of the rural classes in Russia, Charles.....	192

	Page.
United effort for farm betterment and rural progress.....	192
Agricultural credit banks of the world.....	192
Cooperative credit associations in Canada, Doherty.....	192
The work of the special agricultural credit institutes in 1912.....	192
Government valuation of land.....	193
Studies of primary cotton market conditions in Oklahoma, Sherman et al.....	193
Example of successful farm management in New York, Burritt and Barron....	193
What I know about farming, Grinnell.....	193

AGRICULTURAL EDUCATION.

Agricultural and forestry instruction in Italy, Kastner.....	194
[Agricultural and forestry instruction in Austria and Italy].....	194
Anniversary of the Imperial Royal High School of Agriculture of Vienna.....	194
Report of the department of agriculture of Norway, 1912.....	194
World's dairy schools, trans. by Monrad.....	194
Practical School of Aviculture.....	194
Vocational education, Small.....	195
Importance, extent, and execution of student practice at agricultural schools.....	195
Efforts to reform the system of gardening instruction, Schechner.....	195
Uniformity in instruction in the lower agricultural schools, Jachimowicz.....	195
Farmers' institutes in Kansas, Johnson.....	195
A catechism of agriculture, Atkeson.....	195
A course in agriculture for the high schools of Michigan, French.....	196
Principles of agriculture through the school and home garden, Stebbins.....	196
Practicums for pupils in chemical laboratory of agricultural schools, Kwisda...	196
A child's plaything as an expedient in forestry instruction.....	196
The story of our trees, Gregson.....	196
Common trees: How to know them by their leaves, Hillyer.....	196
The planting of home grounds, Davis.....	196
Wisconsin Arbor and Bird Day annual, 1913.....	196
Illinois Arbor and Bird days, Blair.....	196
Arbor Day program, April 25, 1913.....	197
Farm arithmetic, Burkett and Swartzel.....	197
List of references on rural life and culture.....	197

MISCELLANEOUS.

Twenty-fifth Annual Report of Colorado Station, 1912.....	197
Twenty-fifth Annual Report of Massachusetts Station, 1912.....	197
Monthly bulletin of the Western Washington Substation, September, 1913....	197
Organization of the Department of Agriculture, 1913.....	197
Organization and conduct of a market service in the Department of Agriculture.....	197
List of publications of the Department of interest to farm women.....	197

EXPERIMENT STATION RECORD.

VOL. XXX.

FEBRUARY, 1914.

No. 2.

There is an impression that the progress in experimental work on the feeding of farm animals is not all that might be expected or is desirable, considering the importance of the subject and the prominence it has held in the past. This feeling was voiced in the address of a former president of the American Society of Animal Nutrition, who expressed the belief that "nutrition investigations are falling behind other branches of agricultural science"—that there had not been a comparable scientific activity in comparison with other departments in the field of agriculture. Other speakers before that society have recently expressed a similar view; and such a conclusion would seem to be a fair deduction from the output in the form of publications.

This impression applies not only to the amount of fundamental investigation in animal nutrition, but to the character and progress of the ordinary experimental work. Not that there has not been an increase in the amount of advanced work, and an improvement in many of the common feeding experiments, but that relatively the improvement has been small. With the progress of experiment station work and the larger emphasis on investigation, it seemed reasonable to expect that more institutions should feel the need of departing from the conventional range of feeding experiments and more men representing animal husbandry at the stations should feel impelled to prepare for advanced and productive inquiry.

With some notable exceptions, the work in animal husbandry is to a considerable extent at a standstill. The easier things have been done. The more difficult and constructive stage has been reached, but there has not been a very large rising to the emergency. It is only rarely that a feeding project of Adams fund grade is submitted nowadays, but the experiments of conventional type go on apparently without end and, it is feared, without marking much permanent advance.

Quite a proportion of the feeding experiments still deal only with the economic and commercial phases of the subject, or with comparative values and effects; and as economic conditions are constantly changing and vary in different localities, the results lack

permanent or widely applicable value. Hence it is that the necessity is felt for going over much the same ground at frequent intervals and in different localities. And while this is not without value to the farmer it often represents an unnecessary waste of effort, and stands in the way of what might mark more real progress. Essentially the same kind of experiments are often repeated by stations in the same general locality, and with full knowledge of such repetition, as was the case a few years ago when silage was being tested for beef production. The result in such cases becomes largely a local demonstration rather than the acquisition of new information. In fact, the statement has often been made that the work was done to convince the farmers of the locality of the truthfulness or application of work in other States, the thought being that they had a different feeling if the experiments were made under their conditions.

There is undoubtedly much merit in the conventional feeding experiments and in experiments which interpret the best experience of the locality. But such experiments should profit by what has gone before, and should show improvement in method and in the extent to which the results contribute to a more complete understanding of the general subject. Manifestly the experimental results must be secured under such conditions as to insure accuracy and reliability within reasonable limits, and to make possible the comparison of the results with other experiments. At present there is the widest variation in experiments of this class. Between the feeding trial that deals only with the gross effect as measured by lots, and the more refined experiment which carefully guards and controls the conditions and results as applied to individual animals, and seeks the reason in the changes which actually take place, there is a wide gap. One is the rough comparison such as a feeder might make, if he had the time, and the other represents an attempt to trace the true relation between cause and effect.

It would seem that we should have largely passed the stage of the first type mentioned, but the publications and records of work in progress do not show this to be the case. Such trials, with all their crudeness, meet a popular demand and this demand is being acceded to despite the development of demonstration and extension work. Unfortunately there are some indications that the latter is already constituting a new demand for superficial work. This more direct teaching of the farmers brings out local problems in increasing numbers, and makes an urgent call for very practical and didactic directions which have behind them the force of local experimental trials.

But the experiment station can not afford to look at the subject of feeding from the superficial and local standpoint, and it is hardly its function to make experiments to demonstrate locally what is already known. Extension work will be an actual disadvantage to

experimentation if this requirement is pressed beyond reasonable bounds, and the extension worker must realize the need of thorough-going work.

A thorough understanding and sympathetic relation between the station men and the extension men is highly desirable. The latter coming in more direct contact with the farmers are in position to explain the station's work and to justify its position. They are also in position to call to the station's attention, in a discriminating way, larger questions in animal feeding which need study. But the extension men must be reasonable in their expectations of the stations, and they must also realize that after all the chief object of extension teaching is to enlighten the farmer and to help him in making himself more resourceful. Rules for farming to be followed blindly and implicitly can rarely be developed, and would be a serious detriment to the men engaged in the industry if they could be supplied; while carefully made and interpreted experiments can develop facts that will be of wide application, which may be tested out and adapted to the region. But the demonstration of such facts for the information or convincing of the farmers is a matter for the extension department. Such demonstrations will frequently embody some experimental features, since it is rarely possible to adapt locally the teachings of the stations without some special modifications which arise from local conditions. This is invariably the case in everyday life. Matters of convenience, expediency, personal preference, etc., modify human conduct. Similar considerations will inevitably modify the local practice in agriculture which the extension department will succeed in implanting.

The case of the usual feeding experiment is clearly and fairly set forth in the recent bulletin of Mitchell and Grindley of the Illinois Station. In reference to experiments comparing the fattening effect of systems of treatment, etc., the authors say: "Our knowledge of the principles of animal nutrition is too fragmentary to enable us to foretell with certainty, except when greatly dissimilar, which of two rations for instance will produce the more rapid or the more economical gains in weight for a particular kind of farm animal, no matter how clearly defined or completely analyzed the results may be. Actual experiment with those particular rations is generally essential to a satisfactory solution of the problem. However, the information thus obtained has at best a very limited application to other rations or other conditions, so that such feeding experiments ordinarily contribute little of fundamental importance to the science of animal nutrition."

Although the plan of such feeding experiments is simple, the results are often ambiguous and require much care in their interpreta-

tion. This is common to all experiments concerned with the functional activity of living organisms, and is due to the uncertainty of their following exact rules of uniformity, i. e., to what we designate as individuality.

Mitchell and Grindley have presented a most interesting and suggestive study on this element of uncertainty in the interpretation of feeding experiments. It is one of the most effective critical studies of any branch of our station work, and should be very helpful in directing attention to the improvement of experiments of this class and their interpretation. The bulletin illustrates not only the danger to be guarded against from a scientific standpoint, but to an even greater extent when deductions are to be made for the guidance of the farmer, because the latter often can not impose the precise experimental conditions required.

Manifestly experiments of this class are crude and hence lacking in absolute accuracy. This should be recognized to guard against overconfidence and too broad generalizations; and at the same time the effort should be put forth to improve the methods both in planning and execution. As a first step we need to know for our own information the extent of the experimental error and its source. Until we do know this the necessity of improvement is not apparent and its means is uncertain. Refinement of certain stages of the feeding may be more than counterbalanced by the inherent errors due to poor selection of animals or some other defect. The extent of the experimental error is an index to the degree to which deductions can be safely drawn, and will indicate caution in making broad generalizations for the benefit of the practical feeder.

The extensive review of experiment station literature in the United States made by Mitchell and Grindley develops the nature and the source of the experimental error and points to methods of reducing it. They find an average coefficient of variation in gain of about twenty-one per cent for similarly treated lots of sheep and of about seventeen per cent for steers and swine. This points to the danger of small lots of animals and of uneven selection of individuals. As the authors say, "increasing the size of lots is no remedy for a poor selection of experimental animals," and "can not eliminate individuality by merely reducing its effect on the average." Furthermore, "the necessity of selecting homogeneous lots of animals is not appreciably diminished by the balancing of heterogeneous lots."

The critical analysis represented by this bulletin points out the inherent weakness of such experiments, as commonly made, and the need of more scientific and dependable methods in our present feeding trials. They are not all that they should be or might be made, and they are not all that we have assumed them to be. Whether

or not the more abstract research in nutrition is entered upon, experiments for the benefit of practical feeding should carry all the conviction which accuracy of plan and method and judgment in interpretation can make possible.

Some improvement is to be noted in the feeding experiments of recent years, but it is doubtful whether an increasing proportion of such experiments are made under more exact and better-known conditions than formerly—whether the individual records are taken, the feed subjected to analysis, the limits of experimental error considered, and other refinements observed. Indeed, there seems in a considerable number of cases to be less regard for these factors than formerly.

Furthermore, there does not appear to be a very critical attitude toward these feeding experiments by many of the men who make and apply them—the animal husbandmen and animal feeders. The experiments are rarely weighed in the critical, discriminating manner that characterizes scientific work in general in the attempt to measure their true value and the advance which they mark. The expectations are less exacting, and the standard of requirements seems to change but little as time goes on. Apparently the need of a broader special preparation along scientific lines for experimental work in animal husbandry is not very generally felt, while the same importance as formerly is attached to the practical aspects of the subject, sometimes to the overshadowing of others. In other words, it would appear that the standards and ideals, and to some extent the preparation, for work in animal husbandry have not developed to the extent that they have in some other branches of agriculture, and that the setting off of the subject as a separate division and assignment of the feeding studies to it has not been followed by the general strengthening of the experimental work that is clearly desirable.

This is not said in any spirit of harsh criticism of the animal husbandman, or lack of appreciation of the requirements placed upon him. It is made rather as a comment on the condition and attitude which is believed to impede the progress in animal feeding, and is directed at the animal husbandman because he now has such an important relation to this progress. Not that he will necessarily be the one himself to conduct the research in a larger degree, but that as representing the head of animal husbandry work he must furnish much of the spirit and the encouragement and the defense for advanced study, and that his ideals will inevitably influence the character of the activities. If his attitude is not progressive and appreciative of work and methods which aim beyond economic considerations, such work will rarely flourish in his institution.

As a leader of sentiment in his field his influence as well as his actual direction of work is very broad. To him falls the application

and adaptation of the findings of experimental study and the presentation of them to the student and to the farmer. And on him rests in large degree the furnishing of the initiative.

Whether research flourishes or decays depends ultimately on the ideals and conceptions of the class it seeks to serve. If there is not a desire for it and an appreciation and belief in it which constitute a sustaining influence, it can not rise above the mediocre.

It is unreasonable to expect that the animal husbandman, more than the agronomist, will be alike investigator, teacher, and extension worker at the same time, but if he is to be assigned to the experiment station force he should be capable of taking an active and intelligent part in investigation. If he is to take a vital part, and not merely attend to the mechanical operations of feeding and handling the animals, it is not sufficient that his training should make him a good judge of stock and a successful feeder and breeder, but he must have an insight into the method and the spirit of inquiry, and familiarity with the progress of investigation in his field along the theoretical as well as the applied side. These things will require training in science beyond that given in the agricultural course. They mean special preparation for investigation and for its direction. Lack of training in animal physiology and other sciences which will open the way for broader inquiries will constitute a serious handicap to the animal husbandman as a station worker and necessarily impose limitations.

In the system of organization which is becoming common in our institutions, the animal husbandman may be called upon to outline and direct investigations within his department that involve the various branches of science concerned. Unless he is able to see the needs of such investigation, to suggest problems and points of attack and to make himself a part of the investigation, he will have only a passive relation to it and can hardly be expected to take a vital interest in it.

A well known investigator has said: "That researches directed to immediately practical results frequently fail to yield all that may be expected of them is largely due to the imperfections of the scientific work of the past, and so makes evident the importance of undertaking in the present purely scientific studies which will lead to more definite and valuable results when future experiments are directed to the solution of practical problems."

This is equivalent to saying that the practical efficiency of feeding trials depends on knowledge of the principles and scientific facts underlying nutrition. If our understanding of the principles of physiology and chemistry is deficient, it is impossible to account for or explain results secured in practical experiments, or to interpret

them intelligently—an experience which has not been unusual in the past. If, for example, in a practical feeding trial including equal amounts of protein materials from different sources different results are secured from those expected, we are thrown into confusion because having assumed all proteins to be alike we have no explanation to offer. The investigation of these bodies has made the experimental feeder more resourceful in planning and interpreting his work.

Dr. Armsby has well said: "If we believe at all in the utility of applied science, surely we must believe that a study of the intricate workings of the animal machine will yield results of practical value, even though we can not foresee in just what direction."

Animal feeding is by no means a matter of applied mathematics, as was long ago said, but there are certain physiological principles and laws which the animal body follows in the handling and utilization of food, and the knowledge of these must constitute the basis not only for the theory but for the right practice of feeding. It is reasonable to suppose that the necessity for investigation in this line should have impressed itself, and that there should have been a steady development in that direction, along with the experiments of more direct application.

It is clear, of course, that such questions as the maintenance requirements of animals, the interesting question of the influence of feed supply on growth, the protein requirements of farm animals, the functions of protein in the mechanism of the liberation of energy for work, can never be solved by the methods of the common feeding experiment. They call for all the resources of physiological investigation. They tax man's ability and ingenuity and perception to the utmost. The field offers all the inspiration of opportunity for the very best research ability. Some of these subjects and such questions as the constitution and nutritive value of proteins, the function and transformation of nucleo-proteins, and the metabolism of these and other bodies are being studied by physiologists and physiological chemists and not by the animal husbandmen. This is natural, and is immaterial as long as the latter take heed of the results of such work and apply them in their experiments and their teachings. It is not alone benevolent tolerance that is desired for such research, but intelligent and active support for it and a measure of participation in it by those who stand for animal husbandry.

The nature of the subjects which need to be studied and taken account of in their bearing on animal nutrition, and the trend of investigation under way, have been effectively set forth at several sessions of the Graduate School in a way to open up the broader relations of the subject, and also in the proceedings of the American Society of Animal Nutrition. Such study does not always require a

respiration calorimeter, although it calls for adequate laboratory equipment, and it is not necessarily beyond the means of an institution, although ordinarily expensive. Studies that would doubtless cost less than the customary feeding trials might well yield far more to enrich the body of established fact and make the next step possible. After all it is largely a matter of attitude and spirit, for with these the means will follow.

A by-product of nearly every serious investigation in feeding is a series of problems which are suggested as needing investigation. This is the experience of every keen investigator. He encounters questions which he needs light upon, and when he undertakes to search them out in the literature he finds they have not been solved—perhaps worked on fragmentarily by several men and then left in the doubtful stage, with an indeterminate degree of finality.

Many of the large questions in animal nutrition call for cooperation which will bring different branches of science to bear upon them. As President Waters has well said: "The animal husbandman must be content to share the plan, the work, and the credit with other departments of the station. The besetting sin of our present organization of the experiment station and the cause of much of our superficial work is the unwillingness or incapacity of our men to combine themselves into a team and attack a problem as an institution rather than as an individual or as one small department of the institution. . . . We constantly are seeking the lines of cleavage between departments of the station when we should be seeking the means of knitting them together into one whole. The latter is the modern practice of well-organized team work, the former ancient and inefficient individualism." The animal husbandry department furnishes the nucleus, and many will furnish the problems, around which such effective cooperation may be organized.

Cooperation among institutions working along a common line offers many opportunities for helpfulness. A plan for such cooperation was outlined by the Committee on Experiments of the American Society of Animal Nutrition several years ago, to include an investigation upon the optimum protein supply of fattening cattle and the digestibility of feeding stuffs with pigs. Thus far, aside from a passing interest of the members of the society, the results have been largely negative and the proposal has not met with the response that was hoped for. However, the committee reported at the last meeting of the society that it still believed the plan "will be of considerable service to experiment station workers in their attempts to solve some of the problems of animal nutrition." It deserves to be tried. The accumulation of a body of comparable data secured in accordance with a common plan and purpose would be an important step and would mean far more than separate, inde-

pendent experiments which embody nothing in common and are incapable of comparison or combination.

The importance of the subject of animal feeding merits the very best effort which the experiment stations are capable of commanding. The conventional experiments have served a very useful purpose and will continue to be needed, but they should be refined to give a greater degree of accuracy and should be subjected to more critical examination in their planning and their conduct. But beyond this, one of the ultimate objects of work in this field, as in every other, must be to make practice more intelligent and better understood. This calls for the determination of the reason for what is found in experiment and observed in good practice. Without this the theory of feeding can not be developed and the more practical experiments can not reach their highest degree of reliability or usefulness.

One of the greatest needs is more men of training who can see the field in its broader aspects and develop a point of attack. Especially, there should be no question of the encouragement and defense of the higher types of work by the men in charge of animal husbandry in the agricultural colleges and experiment stations.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

In regard to the constitution of albumin, R. CHODAT (*Abs. in Chem. Ztg.*, 36 (1912), No. 52, p. 487).—A special reaction is described which is supposed to be characteristic of the α -aminocarboxylic acids of the fatty series, peptids, simple or complex peptid chains, polypeptids, peptones, albumoses, and soluble proteins. The method is as follows: A purified tyrosinase is allowed to act upon a phenol; i. e., p-cresol, pyrocatechol, etc., in the presence of equimolecular or multiple quantities of an amino acid, a peptid, or a polypeptid. The reaction is indicated by a red coloration which changes to a violet green and finally to a blue having marked red dichroisms, and is very sensitive.

The following among other substances were studied: Glycocoll, d- and l-alanin, d-valin, d- and l-leucin, phenylglycin, d- and l-tyrosin, d- and l-phenylalanin, arginin, and cystin. Anthranillis acid does not react, but with tryptophan and pyrrolidincarboxylic acid a stronger coloration is obtained. Peptones and albumoses give a marked coloration which becomes stronger as peptonization proceeds. The color is also marked in the case of albumins, pure globulins, nucleo-globulins, and other proteins. The reaction will also show a change in the condensation or alteration in the composition of the original protein. As the reaction is specific for amino acids, it determines without going any further the presence of NH_2 - and COOH -groups.

A preliminary note on the coagulation of proteins by ultraviolet light, W. T. BOVIE (*Science, n. ser.*, 37 (1913), No. 940, pp. 24, 25).—In order to gain insight into the action of ultraviolet light on living cells, tests were conducted with ordinary egg albumin, crystallized egg albumin prepared according to the Hopkins and Pinkus method, egg albumin (Hopkins and Pinkus) dialyzed against tap water, and ox serum.

In all instances the albumin was more or less coagulated, and in the case of the egg albumins the coagulum produced was insoluble in alcohol, hot or cold water, and dilute acids, but soluble in dilute alkalis. In these respects it corresponded to the coagulum produced by heat alone.

New investigations in regard to our knowledge of fats, R. LIMPRICH (*Neue Untersuchungen zur Kenntnis der Fette. Inaug. Diss., Univ. Münster, 1912, pp. 89, figs. 9*).—The first part of this work embraces a study of methods for determining the presence of beef or mutton tallow in lard. It describes a new method for this purpose, and gives the results of a study of the Polenske method and its theoretical foundations.

The second part deals with heptadecylic acid and triheptadecylene, the former having been previously found by other investigators to be present in lard in the form of a glycerid. An attempt was made to prepare the heptadecylic acid synthetically and to compare it with the compound occurring in lard.

The third part of the dissertation gives the results of some feeding experiments with carp, with special reference to the influence of the fat given in the food on the body fat of the animals.

Reducing power of sugars (monosaccharids), and its bearing on the definition of these substances, N. SCHOORL (*Chem. Weekbl.*, 9 (1912), No. 35, pp. 706-711; *abs. in Jour. Chem. Soc. [London]*, 102 (1912), No. 600, I, p. 750).—The introduction of a nonoxidized carbon atom between the CO- and CH(OH)-groups in a compound containing the group .CO.CH(OH). diminishes the reducing power materially toward weak alkaline copper solutions. The author maintains that the term "sugar" should include all substances containing the group .CO.CH(OH)., whether they are polyhydric alcohols or not.

Studies in regard to plant colloids.—I, Swelling of the starch solution in the presence of crystalloids, M. SAMEC (*Kolloidchem. Beihefte*, 3 (1911), No. 3-4, pp. 123-160, figs. 7).—The presence of a crystalloid seems to change the swelling of starch granules in lower concentration than was usually supposed. This is apparently due to the anions, and the cations have only a quantitative influence upon the action exerted by the anions. The influence of the inorganic and organic crystalloids, glucose, urea, chloral hydrate, glycerin, etc., upon the swelling process of starch and gelatin with few exceptions is identical.

The stimulation of swelling for the ions investigated is a periodic function of the atomic weight of the respective element. Classification according to the nature and intensity of the swelling process leads to the figures obtained by Pauli and Hofmeister. The swelling induced by certain salts was found to be reversed with an increase in temperature. Salts yielding OH on cleavage in medium concentrations seem to induce swelling.

Acids do not show as great a sensitiveness toward starch as salts. The same conditions for swelling hold for acids as for salts, and, in addition, the condition of the solution (solvate) is modified by the respective acid. Bases stimulate the swelling in highly dilute solutions, and in the lowest concentrations alkali hydroxids show the greatest influence in this direction. The curve (swelling) of most salts points to the formation of ion-adsorption compounds with starch, while the swelling produced by alkali hydroxids can be explained in the light of Pauli's theory of ion hydration. The influence which other crystalloids exert upon starch appears also to be due to lyotrop activities.

On the starch of glutinous rice and its hydrolysis by diastase, Y. TANAKA (*Jour. Indus. and Engin. Chem.*, 4 (1912), No. 12, p. 918).—This presents corrections of an article previously noted (*E. S. R.*, 28, p. 407).

Investigations in regard to the formation of enzymes.—VII, About the development of certain yeasts in various nutrient solutions, H. EULER and B. PALM (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 81 (1912), No. 1-2, pp. 59-70, figs. 6).—The results show that the quantitative multiplication of cells of *Saccharomyces cerevisiae* (beer yeast), *S. apiculatus*, and *S. marxianus* in a solution of an unfermentable disaccharid and fermentable hexose proceeds in the same manner. Apparently yeasts contain hydrolyzing enzymes for certain disaccharids, the fermentation of which can not be determined by existing methods.

The nutrient solution in addition to the sugar was composed of 0.25 gm. of magnesium sulphate, 5 gm. of orthomonopotassium sulphate, and 4.5 gm. of asparagin and water to make 1 liter. The sugars studied were saccharose, glucose, galactose, and lactose.

S. thermantitonum was also tested in this regard but with negative results.

Formation of alkali by enzymes, C. NEUBERG (*Abs. in Zentbl. Physiol.*, 26 (1912), No. 16, pp. 715-717).—The fermentation of the potassium salt of pyroracemic acid with yeast or yeast juice, prepared by von Lebedew's methods, resulted in the formation of carbon dioxid acetaldehyde and potassium car-

bonate. The same fermentation can be produced with the potassium salt of oxalacetic acid.

The biological analysis of casein antiserum, A. KLEIN (*Folia Microbiol. [Delft]*, 1 (1912), No. 1-2, pp. 101-162, table 1; *abs. in Milchw. Zentbl.*, 41 (1912), No. 23, pp. 720, 721).—The antiserum used in these investigations was prepared by injecting casein solutions into rabbits. It was invariably found that 2 kinds of precipitins were produced, which had the following distinguishing features:

Calcium casein precipitin acts exclusively in the presence of calcium chlorid with an optimum activity at a concentration of 5 parts per thousand. Casein precipitation is the most complete when calcium chlorid is absent, and the precipitation decreases as the calcium chlorid increases. Calcium casein precipitin shows an optimum activity with 2 mg. of casein, and casein precipitin with 0.1 mg. of casein. Both of the precipitins are weakened by diluting the serum with physiological salt solution, or by adding an alkali, but casein precipitin is the more affected. The addition of water to fresh antisera produces a precipitate in casein sera, but not in calcium casein sera. As the antisera grow older, or are heated to 55° C., casein precipitin loses some of its precipitating capacity; no such effect is noted with calcium casein precipitin. In the process of immunizing, calcium casein precipitin first makes its appearance in the sera. The calcium casein precipitation reaction obtained with the casein antisera and lactosera does not detect more than $\pm 1/30$ mg. of casein. Casein precipitins do not detect more than 1/100 mg. casein, and in this respect resemble glycerine-acetic acid. Casein precipitin also inhibits the action of calcium casein antiserum.

Some applications of lacto- and ovosera, B. GALLI-VALERIO and M. BORNAND (*Ztschr. Immunitätsf. u. Expt. Ther.*, I, Orig., 14 (1912), No. 1, pp. 32-41, fig. 1; *abs. in Centbl. Bakt. [etc.]*, 1. Abt., Ref., 55 (1912), No. 8, p. 233).—With a lactoantiserum it was possible to detect casein, particularly in feces and in fats. Likewise it was possible with a fowl antiserum to detect eggs in various foodstuffs.

A contribution to our methods of determining nitrogen in humus, C. B. LIPMAN and H. F. PRESSEY (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 2, pp. 143, 144).—While much work has been done in regard to methods for determining humus in soils, very little appears to have been reported with reference to the determination of nitrogen in the humus. To obtain a more uniform and reliable method for determining nitrogen, the Wilfarth, Gunning-Atterberg, Hibbard, and salicylic acid methods were compared. The soils from which the humus solutions were obtained included light sandy soil from a walnut orchard, Anaheim, Cal., with a humus content of 0.55 per cent; silty clay loam derived from the State of Washington, humus content 8.89 per cent; and tule soil from an island in the Sacramento River, nearly all organic matter, humus content 28.7 per cent.

The Hibbard method gave the highest amounts of nitrogen in all cases except one, thus showing a more thorough digestion, and its duplicate and triplicate determinations showed the best agreement. The digestion was carried out more rapidly than in any other method, and particularly than by the salicylic acid method which, in other respects, came the nearest to the Hibbard method in yielding satisfactory results. Considerable trouble with bumping was experienced with all methods except the Hibbard, in which the digestion proceeded rapidly and quietly in all cases. Its manipulation also surpassed in simplicity and speed all the other methods tested. "In view of the fact, therefore, that the Hibbard method is far superior to the others so far as both accuracy and speed are concerned, its use is urged in all humus nitrogen determinations."

A comparison of some qualitative and quantitative methods for carbonates in soils, E. W. GAITHER (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 2, pp. 138-143, figs. 4).—The author finds that methods which boil soils with mineral acids at 100° C. for determining the carbon dioxid content of the soils are inaccurate as a measure for carbonates in soils, because often the organic matter present in the soil is decomposed by the acid treatment, and results in the evolution of carbon dioxid. This confirms the findings of Marr (*E. S. R.*, 22, p. 511). If, however, the soils are boiled in a partial vacuum at 50° with dilute mineral acids, no decomposition of organic matter takes place, and the evolved carbon dioxid is representative of the carbonates present.

The litmus paper test, when properly conducted, was found to be the best qualitative test known for determining the presence of native carbonates in soils from humid regions. On the other hand, some soils may give an alkaline reaction not due to carbonate but to the products resulting from the hydrolysis of certain minerals which exist in soils, as pointed out by Cameron and Bell (*E. S. R.*, 17, p. 742). Although the reddening of blue litmus paper may be due to the absorption of the base from hydrolyzed litmus salt, the presence of native carbonates in soils can either prevent this selective absorption, or it may cause an interchange of bases to take place. If a native carbonate, which is capable of being decomposed by weak hydrochloric acid at a low temperature, is present in the soil, it is indicated by the bluing of red litmus paper. If no alkalis or basic materials are present which yield alkaline solutions, a reaction is obtained with blue litmus paper.

Soils containing substances which redden blue litmus paper have a tendency to the formation of acids or acid salts, which unite with the base absorbed from hydrolyzed litmus and fail to return another base in its stead. This results in the reddening of the indicator even though no hydrogen ions are yielded to a water solution. It is possible that the soil is capable of producing a physiological action which is similar to that produced by stronger acids yielding hydrogen ions to aqueous solutions.

Polarization before inversion in the examination of molasses by Clerget's method, J. J. HAZEWINKEL and C. LOURENS (*Meded. Proefstat. Java-Suikerindus.*, 1912, No. 21, pp. 635-637; *Arch. Suikerindus. Nederland. Indië*, 20 (1912), No. 27, pp. 1073-1075).—The method recommended is as follows: One-half of the normal weight of the molasses is taken in a 100 cc. flask; then 10 cc. of a solution of neutral lead acetate is added, filled up to the mark with water, from 3 to 5 gm. of bone black added, shaken, and filtered. The polarization is done in a 200 or 400 mm. tube.

The freezing point of milk, J. B. HENDERSON and L. A. MESTON (*Proc. Roy. Soc. Queensland*, 24 (1913), pp. 165-180, pl. 1).—With a view to determining a reliable method by which the addition of water to milk could be detected, tests were made of the freezing point of milk under a variety of conditions. Results indicated "(1) that the freezing point of pure fresh milk samples from herds of cows in southern Queensland never shows a greater variation than from 0.55° to 0.56° C., the mean being 0.555° (this is exactly in accord with Continental experience); and (2) that the freezing point determines with accuracy the proportion of water added to any milk from a herd, and distinguishes with absolute certainty the watered rich milk from the naturally poor milk."

A new scale for determining moisture in butter, E. WÖRNER (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 24 (1912), No. 12, pp. 741, 742, fig. 1).—A description and illustration of the apparatus are given.

A simple test for the determination of butter fat in butter, J. M. DORAN (*Jour. Indus. and Engin. Chem.*, 4 (1912), No. 11, pp. 841, 842, fig. 1).—The method, which simply serves as a control test for the chemical method, is con-

ducted as follows: "The sample of butter, taken with a trier or otherwise, is first warmed to about 100° F. and thoroughly stirred to insure the mass being uniform. About 10 cc. of the sample is placed in a sedimentation tube and whirled in a [hand] centrifuge for a few seconds. The sample should be sufficiently liquid in order to insure a good reading after being whirled in the centrifuge. After reading the amount of the sample on the tube scale, about 5 cc. of gasoline is added and the tube carefully inverted 2 or 3 times, holding the thumb or finger over the top of the tube. Let the solution of fat and gasoline drain a few seconds before removing the finger. Place the tube in the centrifuge and whirl again for 15 or 20 seconds.

"The gasoline dissolves the fat, forming a clear layer on the top. The non-fats, that is the water, salt, and curd, being immiscible with the gasoline and also heavier, form the lower layer. The second whirling drives the nonfats to the lower end of the tube almost completely, at the same time forming a sharp line of division between the 2 layers. The amount of nonfats is then carefully read on the tube scale. . . .

"Care should be taken that this test is made at a fairly uniform temperature in order to eliminate as far as possible the changes in relative volumes due to variations in temperature. In case the sample when first placed in the sedimentation tube is not sufficiently liquid to insure a good reading on being whirled, it may be warmed by placing it in water or in an oven for a few minutes at a temperature not over 110°."

The method yields slightly higher results than the official method.

A simplification of the method for determining the Reichert-Meissl and Polenske numbers, A. GOSKE (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 24 (1912), No. 4, pp. 274-276, fig. 1).—The apparatus consists of a boiling flask, a distilling tube (1 bulb), a Liebig condenser with a flared upper end, a funnel, holding a piece of filter paper, attached with a cork to the lower end of the Liebig condenser, and a 110 cc. receiving flask divided into 10 cc. divisions. The advantages claimed for this apparatus are that (1) filtration after distillation is unnecessary; (2) titration is done directly in the 110 cc. obtained; (3) rinsing of the apparatus is eliminated, and in this way the losses observed in the usual procedure are avoided; and (4) no special preparation of the filter is necessary for the second determination.

Estimation of essential oil in mustard, D. RAQUET (*Ann. Chim. Analyt.*, 17 (1912), No. 5, pp. 174-178; *abs. in Analyst*, 37 (1912), No. 436, p. 309).—It is pointed out that mixing mustard with water previous to distillation and allowing it to stand for some time is often followed by inconcordant results. Micro-organisms develop and exert their activity under these conditions, which results in the loss of oil. "If, however, dilute alcohol be used in place of water, the digestion may be allowed to proceed for even 24 hours without loss of essential oil. Having regard to these conditions, the following method is recommended for the estimation of the oil:

"Five gm. of the mustard flour is mixed in a 250 cc. flask with 100 cc. of water and 20 cc. of 90 per cent alcohol; the flask is now closed and set aside for 6 hours, or heated to a temperature of 35° C. for 1 hour. The contents are then distilled, and 50 cc. of the distillate is collected in a 100 cc. flask in which 10 cc. of ammonia have been placed previously; 20 cc. of tenth-normal silver nitrate solution is now added, the distillation is continued until the 100 cc. flask is filled nearly to the mark, and after the flask has been closed with a stopper carrying a long glass tube, the contents are heated to 85° for 1 hour. When cold, the mixture is diluted to 100 cc., filtered, and the excess of silver is titrated in 50 cc. of the filtrate by means of tenth-normal thiocyanate solution after the addition of nitric acid. The number of cubic centimeters of

tenth-normal silver nitrate used is multiplied by 0.198 to obtain the weight of allyl thiocarbimid in 100 gm. of the mustard. The following percentage quantities of mustard oil (as allyl thiocarbimid) were found in samples of black mustard of different origin: English, 1.39, Greek 1.20, French 1.08, Sicilian 0.99, Italian 0.99, and Bombay 0.81 per cent."

Official methods of analysis adopted by the Texas Cotton Seed Crushers' Association (*Oil, Paint and Drug Reporter*, 82 (1912), No. 6, p. 32c).—The methods are for moisture, oil, ammonia and protein nitrogen, total fatty acids, and refinery losses.

Method for determining the amount of cotton-seed hulls in cotton-seed meal, C. J. KOLE (*Verslag. Landbouwk. Onderzoek. Rijkslandbouwproefstat. [Netherlands]*, 1912, No. 12, pp. 34-47).—It is not deemed possible to obtain a good separation of hulls and meal body by sifting. Determining the crude fiber may give a clew as to whether a large or a small amount of hulls is present in the meal, but the results obtained are not accurate.

The National Experiment and Seed Control Station of Holland, located at Wageningen, uses the following method: Five gm. of the sample is treated in a cylinder with 300 cc. of boiling water and allowed to stand for at least 4 hours. The supernatant fluid is then poured off, and the residue is brought upon a piece of gauze (15 by 15 cm., mesh 10 microns) with the aid of a stream of water. The 4 ends of the gauze are brought together and the mass kneaded with the fingers for the purpose of reducing its size. The mass is then washed back into the cylinder, and when the hulls have sunk the fluid containing the floating particles of meal body is poured off. The cylinder is filled again with water, and when the coarse particles of hull have subsided, the supernatant fluid containing the fine particles of shell and coarse particles of meal is transferred to the gauze. The mass is then rubbed up in a mortar and transferred again to the cylinder. These processes are repeated until all meal body has been removed, when the residue, representing the hulls, is dried. The weight of these hulls is multiplied by an empirical factor $100 \div 72$, which gives the amount of hulls present in the sample.

It is stated that cotton-seed meal commonly contains about 15 per cent of hulls.

The determination of formaldehyde, E. RIMINI and T. JONA (*Gior. Farm. e Chim.*, 61 (1912), No. 2, pp. 49-56; *abs. in Chem. Ztg.*, 36 (1912), No. 87, *Repert.*, p. 401; *Chem. Zentbl.*, 1912, I, No. 14, p. 1147).—Riegler's method, based on the conversion of formaldehyde into formalazin by the addition of a known amount of hydrazin, decomposing the excess of the latter with iodic acid and measuring the resulting nitrogen, is deemed inaccurate because formalazin is also decomposed in an acid solution. Consequently the author decomposes the hydrazin in an alkaline solution in which formalazin is perfectly stable. Potassium iodate can not be used instead of iodic acid.

Extraction of oil by aspiration, J. CHAPELLE and J. RUBY (*Jour. Agr. Prat.*, n. ser., 24 (1912), Nos. 48, pp. 686-688, figs. 2; 49, pp. 719-721, fig. 1).—A detailed description of a method for depriving olives of their oil by aspiration. The machinery required is illustrated.

The effect of kiln drying at 145° F. on the composition of the hop, H. V. TARTAR and B. PILKINGTON (*Jour. Indus. and Engin. Chem.*, 4 (1912), No. 11, pp. 839, 840).—The proper temperature to be used in the kiln drying of hops still being a question in dispute, the authors were prompted to repeat in a limited way some of the work which has been reported by other investigators. For this test 7 samples of Pacific coast hops were used. The temperature used in kiln drying in each instance varied between 120° and 145° F., the latter being the one which is preferred at the present time by Oregon hop growers. "The

drying was begun at the lower temperature and then gradually raised to 145°, at which temperature it was held as nearly as possible until the hops were dried. The temperature was taken with thermometers which were kept just under the floor of the kiln and at that portion of the kiln where the temperature was highest." The kilns employed were, with one exception, ordinary stove kilns, and were representative of those in common use. Comparisons were made with samples of hops which were air dried at room temperature. The determinations made were water, total resins, hard (gamma) resin, beta resin, alpha resin, tannin, and wax.

"The results indicate that there was little if any change in the composition of the hops during the kiln-drying process. It will be noted that [with the exception of 2] samples, the amount of hard resin is slightly greater in the air-dried samples, a result which may be due to the variation in different samples. There was evidently little if any change in the amounts of tannin and wax, considering the possible variation in separate samples. A physical examination showed that the difference in the aroma of the air-dried and the kiln-dried samples was hardly perceptible, different judges varying somewhat in their opinions."

See also previous work (E. S. R., 27, p. 814).

Notes on expressed and distilled West Indian lime oils, H. A. TEMPANY and N. GREENHALGH (*West Indian Bul.*, 12 (1912), No. 4, pp. 498-503).—This gives the results of examining 7 samples of hand-expressed oils and 3 of distilled oils, in which were determined the specific gravity at 30° C., the optical rotation in a 100-mm. tube at 31°, the refractive index at 32°, the citral content by Burgess and Child's method, and the acid value by titration of 5 cc. of the oil dissolved in alcohol with seminormal alcoholic potash in the cold.

In regard to the expressed oils, the results show a somewhat wider divergence between the character of the different oils than is indicated by various authorities. The values for the optical rotation are lower than would be expected, probably because of the expansion of the oil owing to the high temperature at which measurements were made. The citral content and the acid number showed a fairly close correlation but varied markedly in different samples. The citral determination seemed to give satisfactory results. The amount of citral found varied markedly in the different samples, but was lower than is found in lemon oils, which, according to Gildemeister and Hoffman, contain from 7 to 10 per cent of that constituent.

With regard to distilled oils, the samples appeared to be characterized, on the whole, by a lower refractive index, citral content, and acid number, and in some cases a lower specific gravity. The rotation, on the other hand, was in all cases somewhat higher.

"From the above results, it would appear that during the process of distillation with steam (the conditions under which ordinary distilled oil is obtained being practically those of a steam distillation) a certain proportion of the lower and higher boiling constituents are removed. The blue fluorescence due to the presence of a crystalline substance in the higher fractions of the expressed oil is entirely absent in those of the distilled oils. This substance possibly may be the anthranilate which is known to exist in lime oil (Allen), to the methyl ester of which, $C_6H_4(NH.CH_3).COOCH_3$, E. J. Parry^a ascribes the blue fluorescence of mandarin orange oil. This is probably removed during the steam distillation.

"Expressed oil on standing generally deposits a pale yellow crystalline substance known as limettin. Distilled oils do not deposit this body. Limettin is

^a Allen's Organic Analysis, 2 (1907), pt. 3, p. 40.

stated to be dimethoxycoumarin; it is readily soluble in hot water, and it is possible that distillation with steam effects the removal of the limettin itself, or of that constituent of expressed oils which by the action of light may be converted into limettin. (A sample of limettin recrystallized from boiling water was found to have a melting point of 115°)."

Investigations on the extraction of lime juice by milling, H. A. TEMPANY and V. M. WEIL (*West Indian Bul.*, 12 (1912), No. 4, pp. 473-478).—The problems connected with the extraction of lime juice as practised in the West Indies at the present time are in many ways not dissimilar from those encountered in obtaining the juice from the sugar cane. In fact, in many cases old cane mills have been adapted to the purpose of expressing lime juice, and so far as the actual extraction is concerned, the processes in the case of the 2 industries are identical. The efficiency of the mill is computed, as a rule, from the number of gallons of juice obtained from 1 bbl. of limes, but as the size of the barrels and limes, and the juice content of the limes was believed to vary, a test was made with a number of samples of limes from various localities.

"An examination of these results shows that the average weight and volume of a single fruit, as also the acidity of the juice, vary largely according to the locality in which the fruit is grown, the former characteristics varying directly and the latter inversely with the rainfall at the place of origin. The percentage of juice contained in the fruit, however, varies relatively little, amounting approximately to 62 per cent of the total weight of the fruit. This result is of a distinctly unexpected character, since comparison with the sugar cane would tend to the belief that the juice content would be materially less in dry localities. It follows from this that measurement of the extraction of juice, if accurately performed, will afford a reliable criterion of the efficacy of the milling in lime juice works."

Some tests in regard to the residue of juice left in the pressed skins were made, and showed that this was almost a complete check upon the efficiency of milling at the time the sample was taken.

Experiments in lime juice concentration, J. C. MACINTYRE (*West Indian Bul.*, 12 (1912), No. 4, pp. 465-472).—"The experiments in lime juice concentration which are described were carried out for the purpose of ascertaining the loss of acid occurring at various degrees of concentration so as to be in a position to judge whether the cost of steam-jacketed pans or other plant would be justified, and incidentally, to determine the point to which it is most economical to concentrate." A note by F. Watts is appended to this paper pointing out the practical value of the results obtained.

Index to *Zeitschrift für Analytische Chemie*, H. FRESSENIUS and A. CZAPSKI (*Zeitschrift für Analytische Chemie, Autoren- und Sach-Register zu den Bänden 41-50*. Wiesbaden, 1912, pp. 287).—An author and subject index of volumes 41 to 50, issued from 1902 to 1911, is given.

METEOROLOGY—WATER.

Temperature coefficients in plant geography and climatology, B. E. and GRACE J. LIVINGSTON (*Bot. Gaz.*, 56 (1913), No. 5, pp. 349-375, figs. 3).—This paper deals fully with a subject which has been briefly discussed elsewhere (E. S. R., 28, p. 212; 29, p. 719). The direct temperature summations and summations of temperature efficiencies are charted and compared.

"For each of the direct summations, the normal daily mean minus 39, for the date next following the average date of the last frost in spring, is taken as the first term. To this are added the normal daily means, each decreased by 39, for all dates up to and including the average date of the last frost in autumn. . . .

For the summations of temperature efficiencies, the normal daily efficiencies corresponding, respectively, to the normal daily means of Bigelow's tables have simply been added for the same days as in the direct summations, thus giving what may be termed a tentative index of temperature efficiency for growth during the normal frostless season."

The general conclusions reached are that "the method of direct temperature summations has proved itself to give, in a broadly general way and for most of the area of the United States, nearly the same climatic zones as does [the] method of efficiency summations. . . . The similarity between the results derived by these two methods of temperature integration, however, is only superficial and roughly approximate. The ratios of direct summation to efficiency summation range in magnitude, for the mean frostless season in the United States, from a minimum of 7.49 to a maximum of 10.44. A rational and consistent climatic chart represents the geographical distribution of these ratio values; on such a chart the marginal regions of the country are frequently characterized by low ratios and the two main mountain systems appear to control areas of high values. There seems to be no doubt that the ratio here brought forward quantitatively represents a climatic dimension or characteristic, which appears to be some sort of function of the daily normal temperatures upon which this whole study has been based and of the time distribution of these temperature data within the period of the mean frostless season."

British rainfall, 1912, H. R. MILL and C. SALTER (*London, 1913, pp. 372, pls. 4, figs. 87*).—This report summarizes observations at 5,272 stations in Great Britain and Ireland grouped by counties and river basins.

The mean rainfall during the year was 39.31 in., 23 per cent above the average for 35 years (1875-1909), for England; 56.19 in., 19 per cent above the average, for Wales; 49.01 in., 11 per cent above the average, for Scotland; and 44.06 in., 8 per cent above the average, for Ireland. Within the last 32 years for which comparisons are available, two only (1882 and 1903) have been wetter than 1912 in the British Isles.

The report contains special articles on the great rain storm of August 25-26, 1912; the wettest summer in England and Wales; and the "Seathwaite" pattern rain gage.

Evaporation from a plain water surface, J. W. LEATHER (*Mem. Dept. Agr. India, Chem. Ser., 3 (1913), No. 1, pp. 15, pl. 1, figs. 2; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 4 (1912), No. 8, pp. 1186, 1187*).—A description is given of the evaporimeter in use at Pusa, which consists essentially of a circular cement tank 6½ ft. in diameter and 5 ft. deep, with an adjustable pointer for measuring the water level. Records for 1911 and 1912 are tabulated and compared with other data obtained from the observatories at Madras and Lyallpur.

The rate of evaporation during the cold weather months was much the same at Pusa and at Lyallpur but was much higher at Lyallpur throughout the six hot months from May to October. At Pusa during the hottest months the rate of evaporation was three times that of the coldest months, at Lyallpur five times, and at Madras not quite twice that of the coldest months.

Dew ponds and mist ponds, E. A. MARTIN (*Rpt. Brit. Assoc. Adv. Sci., 1912, pp. 530, 531*).—An attempt is made in this article to explain the accumulation of water in these ponds. "The precipitation of mist into ponds, aided perhaps by silent discharges of electricity, and the entanglement of mist-laden salt dust in the hollows in which the ponds lie, are believed to be the means by which some ponds maintain a supply of water all through the year, in spite of the great draft which is made upon them by numerous cattle."

The artesian water supply of eastern and southern Florida, E. H. SEL-
LARDS and H. GUNTER (*Fla. Geol. Survey Ann. Rpt.*, 5 (1912), pp. 97-290, pls. 5,
figs. 17).—This paper, which is the fourth of a series (E. S. R., 29, p. 315),
includes a reprint of a paper on the water supply of eastern Florida (E. S. R.,
25, p. 18), revised to include a report on the water supply of southern Florida.
In the combined reports the artesian water supply is discussed in detail for
each county lying in a section bordering the Atlantic and Gulf coasts, and com-
prising the principal artesian areas of Peninsular Florida.

Report of the interstate conference on artesian water, Sydney, 1912 (*Rpt.*
Interstate Conf. Artesian Water [Aust.], 1912, pp. XV+207+68, pls. 42).—The
proceedings of this conference are reported. They dealt chiefly with the extent,
methods of obtaining, and utilization of artesian waters for agricultural and
other purposes in New South Wales. A number of maps, plates, and other data
accompany the report.

SOILS—FERTILIZERS.

Soil, soil investigation, and soil valuation, F. PILZ (*Monatsh. Landw.*, 6
(1913), No. 10, pp. 298-309).—The author reviews the physics and chemistry of
soils and soil structure with special reference to the question of fertilization
and the use of soil analysis in estimating the value of the soil for cropping
purposes. He demonstrates that the kind, amount, and success of fertilization
depend on the crop, the fertilizer content of the soil, the physical condition of
the soil and subsoil, and other factors, such as climate, cultivation, etc., and
points out that to the average farmer a chemical analysis of his soil means
practically nothing. He suggests the need of keeping accurate records in each
rural district of the physical and chemical conditions of the soils of each farm
and of the other local factors affecting crops in order that each farmer may
obtain definite and accurate information regarding the necessary mechanical and
chemical treatment of his particular soil.

Chemistry, physics, biology, and cultivation of the soil, M. HOFFMANN
(*Jahresber. Landw.*, 27 (1912), pp. 24-60).—Recent reports of investigations on
this subject are classified and reviewed as usual.

Contribution to the study of the soils of the Republic of Argentina, P.
LAVENIR (*An. Min. Agr. Argentina, Secc. Quim.*, 2 (1912), No. 2, pp. 577, figs.
6).—This article describes methods of soil sampling, mechanical, physical, and
chemical analysis, and the methods of soil classification employed by the
chemical laboratory of the department of agriculture of Argentina, and draws
conclusions regarding the practical interpretation and application of the results
of analysis. Analyses are reported of a large number of samples of representa-
tive agricultural soils from the different Provinces of Argentina, most of which
show conditions very favorable to agriculture.

Soil culture in Iceland, P. M. GRUNER (*Arch. Biontol*, 3 (1912), No. 2, pp.
VI+213, pls. 2, figs. 28).—This work reviews the natural history of Iceland in
its relation to the formation of swamps and describes the swamps from the
standpoint of their value as sources of peat fuel and as meadow lands. In
addition there is a somewhat lengthy discussion of garden cultivation as
practiced in Iceland, including descriptions of soils, fertilizers, crops, climate,
and other factors closely related to this work.

The results of mixed cultivation with loam in Finland, A. RINDELL (*Jahrb.*
Moork., 1 (1912), pp. 19-34).—A number of experiments were made in drained
and burnt over peat swamps to determine the beneficial effect of adding differ-
ent amounts of loam supplemented by phosphoric acid, potash, and lime as
fertilizers.

The yield of grain was found to increase with increased loam addition. Fertilization with a mixture of phosphoric acid and potash further increased the yield, and somewhat more than fertilization with phosphoric acid alone, but with increasing loam treatment the difference in yields brought about by the two fertilizers steadily decreased. When practically the same experiments were made using sand instead of loam, the same general results were obtained except that the yields of grain were not nearly so large. The addition of lime showed little or no beneficial effect except where iron sulphid was present in the loam.

Comparative tests of lime and loam treatment of peat soils favored the loam, although the crop yield increased as the application of lime increased up to 2,670 lbs. per acre. It was found that repeated burning in case of certain peat swamps so reduced the nitrogen content that the crop yield was considerably lowered, making the addition of nitrogenous matter necessary.

The heat conductivity of damp sand and loam was found to be three or four times that of the peat. It was also found that loam treatment of peat soils sufficiently arrested frost action to allow plant life to exist in much colder weather. This is attributed to the better physical condition of the soil.

Moor culture, A. KOSTLAN (*Jahresber. Landw.*, 27 (1912), pp. 200-215, fig. 1).—Reports of recent investigations on this subject are classified and reviewed.

The shrinking of swamp soils resulting from drainage and cultivation, B. TACKE (*Jahrb. Moork.*, 1 (1912), pp. 35-45, pl. 1).—Attention is called to the marked shrinking and sinking of swamp soils resulting from drainage and other improvements. A sinking of from 15 to 25 per cent of the soil depth has been found to take place within 15 years after drainage in many swamps, especially in those from which the peat has been stripped. The shrinking and sinking occur in layers and not as a solid mass.

The degree to which drainage so affects the soil is said to depend chiefly on the physical and chemical composition and depth of the soil, on the amount and depth of drainage, and on the character and condition of the subsoil. In some upland swamps which are drained and stripped of peat the bed soil sinks below the water level in the drainage ditches. To obviate this it is suggested that in stripping the peat a bed be left somewhat more than 50 cm. above mean water level in the ditches and this be mixed with sand to reduce the shrinkage. Cultivation of peat stripped soil reduces the shrinkage more than the sand treatment, but the productivity is said to be not nearly so great. The effect of drainage on such soils can best be determined by observing the relative movements of the layers and comparing their densities as determined before and at intervals after drainage.

Investigations on the influence of plant roots on the structure of the soil, M. BERKMANN (*Internat. Mitt. Bodenk.*, 3 (1913), No. 1, pp. 1-49, figs. 6).—A series of pot experiments with two representative soils, one a sandy soil containing considerable humus and little clay and the other a clay loam soil, were conducted over a period of two years to determine the influence of plant roots on the soil structure and also the effect of physical changes within the soil itself. The soils were prepared by tamping some and puddling others into place, and still others were experimented with in a loose mellow condition. Plants representative of the two general types of rooting were grown on some of the soils while others were left bare.

It was found that different kinds of soils, especially those rich in clay, are loosened not only by absorbing water but also as a result of the effect of frost, variations in moisture content, etc. In loose soils a very small percentage of the spaces is filled by the stronger tap roots so that there is no essential decrease in the original mellowness from this source. In compact soils roots may

to a certain degree improve the structure and thus increase production. In compact stiff soils, without granular structure, the loosening process is aided, to the benefit of plant growth, by the mechanical action of roots and by a strong modification of the moisture conditions. Roots apparently seldom make practical use of the so-called "root holes" as a means of spreading in heavy soils. The growth of roots as regards their mechanical action varies in loose and compact soils. The beneficial combination of self-loosening and root action explains the frequent permanent improvement of the soil structure under the continued influence of roots, as in grass lands, and also the prevention of permanent puddling of the soil by rain.

Further studies of the influence of vegetation on the penetration and movement of water in the soils showed a beneficial influence, especially in meadow and pasture lands where there is a marked surface spreading of the roots. Although in these cases the lateral percolation of the water was somewhat retarded by the roots, loss of water through evaporation was also retarded and a comparison of soils with and without vegetation showed that the water movement was much more rapid in the former. However, in grain lands covered with crops only part of the year, an injury resulted and the soil became hard and compact, making frequent cultivation necessary.

The influence of subsoil loosening on soil yield, AUGSTIN (*Illus. Landw. Ztg.*, 33 (1913), No. 32, pp. 303, 304, figs. 2).—The opinion is expressed that the entire breaking up of a subsoil destroys capillarity, induces too much ventilation and drainage, and causes soluble plant foods to leach away. Cropping experiments on soil which had been completely subsoiled and on soil in which the subsoil had been broken only in a small furrow 3 cm. wide under each furrow were in favor of the latter method. Less power was expended in plowing by this method and it is stated that the looseness of subsoil lasts longer.

The minimum water capacity of soils and its cause, A. MOSKOVIĆ (*Jlitt. Landw. Lehrkanz. K. K. Hochsch. Bodenkul. Wien*, 2 (1913), No. 1, pp. 209–243, figs. 3).—The author reviews the results obtained by several other experimenters and gives the results of a number of his own experiments made to determine the cause and limitations of the minimum water capacity of soils.

On the basis of these results the author concludes that the minimum water capacity of soils is the maximum amount of water which is independent of gravity, or that amount which is adsorbed by a permeable soil under certain fixed conditions of vapor and air pressure and temperature when a surplus of water is added. He further concludes that under similar conditions of vapor and air pressure, temperature, stratification, and size of grain every soil except alluvial soil has a constant minimum water capacity. The difference between minimum and absolute water capacity of the soil increases as the soil becomes coarser grained. The minimum water capacity of the soil is determined by the adsorbed or condensed water, so that the greater the condensing surface presented within a soil the higher is the minimum water capacity. However, since the adsorptive power of different soil constituents varies, the minimum water capacity is not proportional to the surface presented but only to the free surface tension. In porous soils the larger part of the water not adsorbed drains away below, but nonporous soils, such as fine grained sands if the grains are of suitable shape, form pores with closed walls which retain large quantities of water, so that such fine sands in spite of their small adsorptive power show a high minimum water capacity. The minimum water capacity of a soil is not altered by crumbling but is increased by puddling, which increases the surface tension.

Quantitative investigations on the reaction of aqueous extracts of soils, T. SAIDEL (*Bul. Sect. Sci. Acad. Roumaine*, 2 (1913–14), No. 1, pp. 38–44; abs.

in *Jour. Chem. Soc. [London]*, 104 (1913), No. 611, I, p. 1035).—An electrical method and apparatus for determining the reaction of soil extracts are described and tests of the method on different kinds of soil are reported.

Alkaline reactions caused by acids and their acid salts in soils. G. MASONI (*Stuz. Sper. Agr. Ital.*, 46 (1913), No. 4, pp. 241-273; *abs. in Chem. Zentbl.*, 1913, I, No. 24, p. 1999; *Jour. Chem. Soc. [London]*, 104 (1913), No. 611, I, p. 1036; *Chem. Abs.*, 7 (1913), No. 19, p. 3381).—"Organic and mineral acids and their acid salts are able to cause an alkaline reaction in soils. In calciferous soils calcium carbonate is formed, which in aqueous solution, on the addition of acid, parts with hydroxyl. The alkaline reaction may also be due to the action of acids on basic salts of magnesium, calcium, or aluminum. Acid alkali salts will give rise to alkali carbonates. The influence of the alkaline reaction on the biological function of the roots is discussed."

The chemistry of humus, with special reference to the relation of humus to the soil and to the plant. S. L. JODIDI (*Jour. Franklin Inst.*, 176 (1913), No. 5, pp. 565-573).—From a review of his own and other investigations the author concludes, in opposition to the earlier idea that humus is made up of but a few organic compounds, chiefly acid in their nature, that "more recent investigations have thrown enough light upon the chemical nature of humus or humus organic matter in the soil to demonstrate that it is a very complex substance which, in addition to the dark-colored humin bodies, contains a large number of organic compounds displaying acid, basic, neutral, and amphoteric character."

The value of humus in soils is attributed not only to the fact that it contains most of the elements necessary for plant life but that it affords a means for rendering more of the necessary inorganic elements available, improves the physical condition of the soil, and in short "makes the soil a more habitable and suitable home for the performance of the life functions of plants."

The nature of humus and its relation to plant life. S. L. JODIDI (*Biochem. Bul.*, 3 (1913), No. 9, pp. 17-22).—This article is substantially the same as the above.

Observations on the influence of plant covering on soil temperatures. J. FRÖDIN (*Lunds Univ. Årsskr.*, n. ser., Sect. 2, 8 (1912), No. 9, pp. 16, pls. 4, fig. 1).—Soil temperatures were observed in midwinter on snow-covered and open soils, both fallowed and planted.

It was found that on the coldest days the temperature at a depth of 10 cm. under the plant covering was the same as at a depth of 17 cm. in fallowed soil. The temperature at 10 cm. in the snow-covered soil was found to be equal to that at a depth of 27.4 cm. in naked soil. Since the plant covering of from 2 to 4 cm. apparently had the same effect as a soil layer 7 cm. thick, and the 10 cm. snow layer the same effect as a soil layer 17.4 cm. thick it is concluded that at the same thickness coverings of vegetation and snow would have the same effect. After a thaw it was found that under the snow the top layer of soil was warmer than a layer 20 cm. deep and that a still colder layer of soil existed between these two. This is attributed to heat radiation through the snow and is said to have a considerable biological and hydrographic influence.

A comparison of the daily ranges in temperature of soil covered with vegetation and fallowed soil showed that at 10 cm. depth the temperature range of the former was only 55 per cent of that of the fallowed soil and that the plant covering acted in this respect as a soil layer 9.1 cm. thick. Comparisons of the daily range in temperature in the same soils on clear quiet days in the late spring showed that the range at a depth of 10 cm. under vegetation was only 59 per cent of that of the fallowed land and that the plant covering acted

in this respect as a soil layer 8.6 cm. thick. It is further shown that the differences in range of temperature between soil covered with vegetation and naked soil have a particular significance to the biology and geography of some plants, especially the so-called Alpine plants.

The use of dialysis and the determination of oxidizing power in judging soils, J. KÖNIG, J. HASENBÄUMER and K. GLENK (*Landw. Vers. Stat.*, 79-80 (1913), pp. 491-534, pl. 1, figs. 2; *abs. in Zentbl. Agr. Chem.*, 42 (1913), No. 5, pp. 289-295; *Jour. Chem. Soc. [London]*, 104 (1913), No. 607, I, p. 578; *Zentbl. Bakt. [etc.]*, 2. Abt, 39 (1913), No. 4-7, pp. 184, 185).—Six different soils, namely, sand, sandy loam, loam, limestone soil, clay soil, and schistose soil, were subjected to dialysis, part in the natural state, part previously heated in a vacuum to from 95 to 98° C., part heated to from 150 to 180°, and part treated with hydrogen peroxid. After dialysis the amounts of organic matter, calcium, magnesium, potassium, phosphoric acid, and sulphuric acid were estimated.

The final results showed that only with dried clay soil did the quantity of substances obtained by dialysis fall below that of the natural soil. It was found that soils heated to 150° yielded more soluble matter than untreated soils. similar results, but less marked, were obtained with the soils dried at from 95 to 98°. The amounts obtained for sandy and sandy loam soils treated with hydrogen peroxid were considerably higher than those obtained from natural soils. From the results obtained, and since much time and considerable care and accuracy are required, it is concluded that dialysis can have no practical application in soil investigation.

Clearer indications of the changes which soils undergo when heated and when air-dried were obtained by estimating the electrolytic conductivity. The results indicate that the ordinary drying out of soils produces a partial suspension of the colloidal conditions and hence an increase in the solubility of the plant food in the colloidal combinations.

The amounts of carbon dioxid produced in six different soils and in the same soils with small amounts of dextrose and urea were estimated daily for three weeks. Contradictory results were obtained with and without dextrose, but at a mean temperature of 15.7° the limestone soil formed the largest proportion of carbon dioxid. At the end of this experiment the amounts of ammonia and nitrates and the number of bacteria were estimated. Urea was almost completely nitrified in the loamy soil while the clay soil showed only very slight nitrification. It was noted that the power of oxidation of a soil stands within certain limits which can not be exceeded within a given time with a given air supply. The addition of dextrose considerably increased the number of bacteria in all the soils, in sandy soils as much as eightfold. The catalytic power was affected in the same way except in the schistose and clay soils. The electrolytic conductivity was increased by clay and diminished by dextrose. It is concluded that determination of electrolytic conductivity is the best method of disclosing the changes taking place in the soil and further that the determination of oxidizing power is a very suitable method of investigating the properties of individual soils.

The results of pot experiments with oats showed that heating the soil at from 95 to 98° in a vacuum increased both the total growth and the mineral constituents. From this it is concluded that alternate drying out and wetting of the soil will promote the formation of soluble plant foods.

The addition of dextrose and gum arabic to loamy sand and loam diminished the yield of grain and straw. This is attributed to an excess of undecomposed sugar in the soil acting as a nonelectrolyte, impeding the movement of the ions in the soil, or as a colloid shield restricting flocculation of the colloids. The

taking up of food from the soil by plants is thought to be effected by an exchange of ions.

The employment of dialysis and the determination of the power of oxidation as a convenient method for the judgment of soils, J. KÖNIG (*Festschrift 84. Versamml. Deut. Naturf. u. Ärzte von der Med. Naturw. Gesell. Münster, 1912, pp. 57-77, pl. 1, fig. 1*).—See also the article noted above.

The soil solution and the mineral constituents of the soil, A. D. HALL, WINIFRED E. BRENCHELEY, and LILIAN M. UNDERWOOD (*Phil. Trans. Roy. Soc. London, Ser. B, 204 (1913), No. 307, pp. 179-200, figs. 2*).—Wheat and barley were grown in solutions made from soils on which wheat and barley had been grown for 60 years. The growth in the solutions was parallel to that on the plats and the composition of the solutions as regards phosphoric acid and potash corresponded to the past manurial treatment and present analysis of the plats. Growth in the solutions from imperfectly manured plats was brought to the level of that in solutions of completely manured plats by the addition of suitable salts. "Wheat grew as well as barley in the solutions of the wheat soils and vice versa. In a similar set of solutions from the same soil the growth of buckwheat, white lupines, and sunflowers corresponded with that of wheat and barley. Boiling effected no alteration in the nutritive value of the soil solutions."

"In nutritive solutions of various degrees of dilution the growth of plants varied directly, but not proportionally with the concentration of the solution, though the total plant food present in the solution was in excess of the requirements of the plant. When the nutrient solution was diffused as a film over sand or soil particles, as in nature, there was no retardation of growth due to the slowness of the diffusion of the nutrients to the points in the liquid film which had been exhausted by contact with the roots. Growth in such nutrient solutions forming a film over sand particles was much superior to the growth in a water culture of equal concentration, but the growth in the water culture was similarly increased if a continuous current of air was kept passing through it."

"From the results obtained it is generally concluded: (1) The composition of the natural soil solution as regards phosphoric acid and potash is not constant, but varies significantly in accord with the composition of the soil and its past manurial history.

"(2) Within wide limits the rate of growth of a plant varies with the concentration of the nutritive solution, irrespective of the total amount of plant food available.

"(3) When other conditions, such as the supply of nitrogen, water, and air are equal, the growth of the crop will be determined by the concentration of the soil solution in phosphoric acid and potash which, in its turn, is determined by the amount of these substances in the soil, their state of combination, and the fertilizer supplied.

"(4) On normal cultivated soils the growth of crops like wheat and barley, even when repeated for 60 years in succession, does not leave behind in the soil specific toxic substances which have an injurious effect upon the growth of the same or other plants in that soil."

The net result of these investigations is thought to uphold the theory of the direct nutrition of the plant by fertilizers.

Results of ten years' comparative field experiments on the action of fallow, manure, and clover, A. KOCH (In *Festschrift zum siebenzigsten Geburtstage von Jacob Esser. Berlin, 1913, pp. 57-93, figs. 3; Jour. Landw., 61 (1913), No. 3, pp. 245-281, figs. 3*).—Three systems of soil treatment were followed in the experiments reported in this article. These compared unfertilized black fallow, manure (on potatoes or beets), and clover in a rotation of three cereals

(winter wheat, rye, and oats or summer barley). The soil used in the experiments was a friable loam.

Detailed data for yield and value of the crops and the nitrogen content of the soil at different periods of the experiments are summarized. These indicate little or no decline of the nitrogen supply of the soil or of yield with bare fallow as compared with the manure and clover rotations.

The addition of cellulose to the soil as a source of energy increased the activity of bacteria which convert nitrates into albuminoid substances, and thus decreased the growth of crops. As soon as the cellulose was consumed, however, no further transformation of nitrates occurred and the plants began to make normal growth. The author concludes from this that nitrates are essential to plant growth in natural soils.

Soil hygiene and green manuring, F. ARNDT (*Mitt. Ökonom. Gesell. Sachsen, 1912-13, pp. 29-70*).—The author discusses soil moisture regulation and physical and chemical harmony in soils, and reports the results of his experiments made to demonstrate the value of legumes for green manuring.

Report of the agriculturist, E. F. GASKILL (*Massachusetts Sta. Rpt. 1912, pt. 1, pp. 21-34*).—This is a report of progress in fertilizer experiments following the same general lines as in previous years, including plat and pot tests (E. S. R., 28, p. 325).

The management of solid and liquid manures, M. RINGELMANN (*Aménagement des Fumiers et des Purins. Paris, 1913, pp. 187, figs. 103; rev. in Rev. Sci. [Paris], 51 (1913), II, No. 7, p. 219*).—This book deals very fully with the methods, structures, and appliances employed in the preservation and handling of farm manures, more especially liquid manures. The subject is considered from the sanitary standpoint as well as from that of practical utilization of the manures on the farm. Methods and appliances for distributing the manures and manure liquors receive particular attention.

Enrichment of farmyard manure by cake feeding, A. D. HALL (*Jour. Bd. Agr. [London], 20 (1913), No. 8, pp. 665-672*).—On the basis mainly of experiments made at Rothamsted, but also from a study of farm accounts, the author concludes that the addition of oil cake to the feed of cattle enriches the manure in quickly available fertilizing constituents, but does not greatly increase its ultimate effect. He is of the opinion that the value of the practice of using cake is overestimated, particularly in case of light soils.

Comparative tests of lime nitrogen, nitrogen lime, sodium nitrate, and ammonium sulphate on sandy and upland moor soils, B. TACKE and F. BRÜNE (*Landw. Vers. Stat., 83 (1913), No. 1-2, pp. 1-100*).—Pot experiments with different crops under a variety of conditions gave results indicating that the lime nitrogen prepared by the Frank and Caro process and nitrogen lime prepared by the Polzenius process are equally effective on sandy soils, but that the nitrogen lime is only about 81 per cent as effective as that of lime nitrogen on moor soils. The experiments indicated that neither product should be applied at the same time as the seed, as if applied at this time the fertilizing effect is only 44 per cent of that of sodium nitrate. Applied as a top-dressing the materials are from 66 to 67 per cent as effective as sodium nitrate in the case of rye and from 80 to 82 per cent as effective in the case of oats and potatoes. The best results were always obtained when the materials were applied a short time before seeding, when they were on the average 89 per cent as effective as sodium nitrate. The utilization of the nitrogen by plants was only 54 per cent of that of sodium nitrate on sandy soils and 67 per cent on moor soils.

The lime-nitrogen industry, E. O. SIEBNER (*Chem. Ztg., 37 (1913), Nos. 106, pp. 1057, 1058; 108, pp. 1073-1075*).—This is a brief review of the present status of the industry.

Nitrogenous fertilizers obtainable in the United States, J. W. TURRENTINE (*U. S. Dept. Agr. Bul. 37, pp. 12*).—Statistics of production and consumption for fertilizing purposes of sodium nitrate, ammonium sulphate, synthetic nitrogen compounds (calcium cyanamid and nitrate), tankage, and dried blood are summarized and discussed.

It is estimated that the use of these materials in fertilizers in the United States during 1912 was approximately as follows: Ammonium sulphate (production in United States 155,000 tons, imports 60,000 tons) 215,000 tons; sodium nitrate (about 13 per cent of the imports, 518,613 tons) 70,000 tons; calcium cyanamid 11,264 tons; tankage 99,324 tons; dried blood 37,710 tons; fish scrap 70,000 tons. See also a previous note (*E. S. R.*, 29, p. 517).

Figures are given which indicate that less than one-sixth of the recoverable ammonium sulphate lost in beehive coke ovens in the United States is now saved. Estimates by the Bureau of Animal Industry indicate that if all the slaughterhouse wastes were saved the possible production of tankage would be 222,535, of dried blood 79,794 tons.

The replacement of potash in certain feldspathic rocks by substances used as fertilizers, G. ANDRÉ (*Compt. Rend. Acad. Sci. [Paris]*, 157 (1913), No. 19, pp. 856–858; *abs. in Rev. Sci. [Paris]*, 51 (1913), II, No. 21, p. 668).—The results reported by the author show the important rôle played by the phenomena of double decomposition which occurs when soluble fertilizing materials are added to the soil.

The replacement of potash by soda was especially marked when microcline was mixed with sea salt or with sodium nitrate, the amount of potash replaced being almost identical in the two cases. This replacement explains the favorable action of salt when used as a fertilizer. Sodium nitrate when applied to the soil is thus a means of furnishing a certain amount of potash to plants as a result of double decomposition in contact with particles of feldspar. Ammonium sulphate is also particularly active in replacing potash.

Investigations on the composition of Thomas slag, M. POPP (*Österr. Chem. Ztg.*, 16 (1913), No. 21, pp. 291, 292).—Four different crystalline forms occurring in Thomas slag are described and their varying solubility in citric acid is discussed. Certain rhomboidal blue crystals occurring in the slag were found to be 95 per cent soluble in citric acid, while the brown columnar crystals found were only 41 per cent soluble.

In ground slag it was found that the finest particles had the highest percentage of phosphoric acid, silicic acid, and lime, and the lowest percentage of iron. Separating the coarser particles by means of an electromagnet it was found that the nonmagnetic part was almost identical in composition with the fine meal. While the phosphoric acid of the coarse particles, as a whole, was 13 per cent soluble, that of the magnetic particles was 20 per cent soluble.

A method of electro-dialysis was tried by which it was possible to separate the particles into groups corresponding to their solubility in citric acid.

Investigations on the action of steamed and unsteamed bone as a phosphatic fertilizer in comparison with superphosphate and Thomas slag as well as on the importance of grinding unsteamed bone, B. SCHULZE (*Land. Vers. Stat.*, 83 (1913), No. 1–2, pp. 101–130).—In a series of pot experiments it was found that the phosphoric acid of Thomas slag soluble in citric acid was about 90 per cent as effective as the water soluble phosphoric acid of superphosphate the first year. Its utilization by plants was about 81 per cent of that of water soluble phosphoric acid. The after effects, however, in a measure compensated for the poor results the first year.

The effect of the phosphoric acid of bone meal during the first year was barely half that of superphosphate. In the course of three years the average

effect of the phosphoric acid of bone meal was about 60 per cent of that of water soluble phosphoric acid. The phosphoric acid of steamed bone meal was somewhat more effective than that of unsteamed bone; the results, however, varied with the plants grown. The difference in effect on cereals and on such crops as mustard, buckwheat, and spurry was especially marked. In no case, however, did the bone meal approximate in fertilizing efficiency the water soluble or citric acid soluble phosphoric acid.

Fine grinding of the unsteamed bone appreciably increased the fertilizing efficiency of the phosphoric acid.

The use of raw phosphate and siliceous lime as fertilizers. T. PFEIFFER (*Zentbl. Kunstdünger Indus.*, 18 (1913), Nos. 21, pp. 457, 458; 22, pp. 473, 474).—Reviewing work by others the author concludes that raw phosphates may be profitably substituted for Thomas slag under certain circumstances, as, for example, on acid peaty soils, but that the conditions under which they are effective need to be carefully studied. The work of Immendorff and others shows that siliceous lime may be applied to soils without injury and even with benefit under certain conditions.

Agricultural value of carbonate of lime recovered from causticizing plant. J. HENDRICK (*Rpt. Brit. Assoc. Adv. Sci.*, 1912, p. 741).—This material is described and field experiments with it are reported which showed that it compared favorably with other forms of lime as a fertilizer.

The action of quicklime on the soil. H. B. HUTCHINSON (*Rpt. Brit. Assoc. Adv. Sci.*, 1912, p. 740).—Observations are reported which show that the addition of small quantities of quicklime to field and garden soils stimulates general bacterial growth, but that large quantities cause an initial depression in the numbers of bacteria, the destruction of certain large protozoa, and a cessation of all biological processes. When the lime is converted into carbonate or combines with the soil constituents there is a great increase in the number of bacteria and acceleration of ammonification.

"The length of the period during which bacterial growth is suspended would appear to be determined by the quantity of lime applied, the initial reaction of the soil, and the amount of organic matter present.

"Pot experiments have been carried out with variously limed soils, and the crop results show close agreement with those obtained by bacteriological and chemical analyses."

Mineral and nitrogen contents of pine needles and straw. H. BAUER (*Ztschr. Forst u. Jagdw.*, 45 (1913), No. 10, pp. 659, 660).—Analyses of needles and of straw of *Pinus cembra* in various stages of decomposition are reported. The percentages of ash and nitrogen were found to be very small but increased with the age of the material. The increase of mineral constituents with age and stage of decomposition was especially marked in the case of the lime. The potash on the other hand decreased with age.

Tobacco stalks as a fertilizer. H. D. HASKINS (*Massachusetts Sta. Rpt.*, 1912, pt. 2, pp. 80-84).—This article gives analyses and discusses the fertilizing value of various samples of leached and unleached tobacco stalks. Stalks obtained in the so-called priming system of harvesting the crop contained much less fertilizing matter than those obtained by stripping in the ordinary manner. Stalks which had been allowed to lie on the land during the fall and winter months had lost about 57 per cent of the total nitrogen and 51 per cent of the total potash.

Chemical industries of Belgium, Netherlands, Norway, and Sweden. T. H. NORTON (*U. S. Dept. Com. and Labor, Bur. Foreign and Dom. Com., Spec. Agents Ser.*, 1912, No. 65, pp. 85).—Data regarding the production of various

materials used as fertilizers and for other agricultural purposes are included in this report.

Report of the fertilizer section, H. D. HASKINS (*Massachusetts Sta. Rpt. 1912, pt. 1, pp. 103-118*).—A brief account is given of the State fertilizer inspection and the character and quality of fertilizing materials used in the State are discussed.

AGRICULTURAL BOTANY.

The action of certain nutrient and nonnutrient bases on plant growth, M. M. McCool (*New York Cornell Sta. Mem. 2, pp. 115-216, figs. 15*).—This memoir consists of three papers as follows: (1) The antitoxic action of certain nutrient and nonnutrient bases with respect to plants, (2) the toxicity of manganese and the antidotal relations between this and various other cations with respect to green plants, and (3) toxicity of various cations.

Extensive studies on the toxic and antidotal action of various ions were made, and the chief conclusions which were derived from the experiments are that barium, strontium, ammonium, magnesium, sodium, and potassium were poisonous to seedlings in the order given. Mutual antagonism resulted when the following cations were present in solution: Magnesium and strontium, potassium and strontium, sodium and strontium, sodium and potassium, sodium and ammonium, potassium and barium, and magnesium and barium. Calcium was found the most effective of any of the substances studied in preventing toxic action. This protective action was found to be not confined to the so-called essential nutrients, as some of the nonessential ions possessed this property. The favorable results obtained from the application of lime to many types of soils is believed to be due in part to the antidotal relations.

In considering the toxicity of manganese the author studied its effect in various cultures, using pea and wheat seedlings. It was found that pure solutions of manganese salts are extremely poisonous to pea and wheat seedlings, and that the degree of toxicity is greatly reduced by full nutrient solutions and by soil cultures. The injurious action of the manganese ion is manifested mainly toward the tops of plants, chlorosis of the leaves being the first indication of an overdose of manganese. Manganese was found less injurious to plants grown in the dark than to those in the light, and the ions of calcium, potassium, sodium, and magnesium were effective in counteracting the poisonous action of manganese.

In the report upon the toxicity of various cations the author reviews the literature and summarizes his investigations, showing that barium, strontium, ammonium, magnesium, sodium, and potassium, in the order given, when present in pure solution are very toxic to seedlings. This toxicity is greatly reduced by either full nutrient solutions or soil cultures. Under the conditions of the experiments much stronger solutions were required in order to prevent top growth than to kill the roots of seedlings. Seedlings which had been grown for 10 days either in distilled water, tap water, or full nutrient solutions were found more resistant to the toxicants studied than those which were placed immediately in the toxic solutions.

Bibliographies of literature are appended to the different papers.

Application of fertilizers to plants through their leaves, P. LARUE (*Rev. Vit., 40 (1913), No. 1028, pp. 261-264*).—Experiments suggested by the reports of Hiltner on his work in applying fertilizing solutions to aerial portions of plants (*E. S. R., 27, pp. 324, 651*) were carried out by the author with various plants.

Potatoes were increased in weight by the use of several different applications. Results with mustard and soy beans were variable, some compounds tested appearing toxic. In case of grapevines the conclusion is reached that mixtures used against attacks of fungi, etc., may be so proportioned as to give these sprays a decided value as aerial fertilizers if the necessary higher degree of adherence can be secured to prevent their removal by rains.

Saponins as a source of carbohydrates for vegetation, F. SOLACOLU (*Compt. Rend. Soc. Biol. [Paris]*, 74 (1913), No. 6, pp. 304-306).—The author reports on culture experiments with *Aspergillus niger* and *Penicillium glaucum* in nutritive media containing various saponins named, most of which were commercially prepared, stating that all served as nutritive material for these fungi.

Studies on the distribution of asparagin, glutamin, arginin, and allantoin in plants, A. STIEGER (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 86 (1913), No. 4, pp. 245-269).—The results are given of investigations carried out regarding the occurrence and proportion of these products in various portions of the plant body, numerous families of plants being represented in the study.

It is stated that asparagin and glutamin were frequently found together in various proportions and sometimes in different families, leading to the conclusion that these products are in some instances used or stored at very unlike rates, the differences in this respect being apparently family characteristics in certain cases. Arginin almost always accompanied asparagin, but less regularly glutamin. Allantoin showed no such close relation to the other compounds in question and no conclusion was reached regarding the part it plays in plant economy.

The formation of the anthocyan pigments of plants, VI, F. KEEBLE, E. F. ARMSTRONG, and W. N. JONES (*Proc. Roy. Soc. [London]*, Ser. B, 87 (1913), No. B 593, pp. 113-131).—This is in continuation of a series of papers (E. S. R., 29, p. 421), the present one dealing with the pigment-producing glucosid of the wallflower, the formation of pigment-producing substances from glucosids, and the biochemistry of Mendelian color characters.

The pale yellow sap color of the petals of the wallflower is said to be a mixture of hydroxyflavone glucosids. The hydrolyzed product if reduced and subsequently oxidized yields a red pigment. The fact that flowers containing yellow pigments may be caused, by chemical treatment, to yield a red pigment suggests that red mutations should be of possible occurrence within the species. The formation of pigments, as the results of oxidation by oxidase of the hydrolyzed products of glucosids, is determined by the presence of aminocompounds and is of general occurrence.

The authors give a classification of pigments as determined by their investigations. It is suggested as a hypothesis that the higher members of a flower color series owe their origin to the presence with the lower members of specific substances which, acting as receivers of oxygen, reduce the pigments characteristic of the lower members of the color series, accept oxygen therefrom, and thereby become oxidized to pigments of specific color.

Synthesis by sunlight in relationship to the origin of life.—Synthesis of formaldehyde from carbon dioxid and water by inorganic colloids acting as transformers of light energy, B. MOORE and T. A. WEBSTER (*Proc. Roy. Soc. [London]*, Ser. B, 87 (1913), No. B 593, pp. 163-176).—The authors found that organic matter (aldehyde) was synthesized from inorganic colloidal uranic and ferric hydroxids in very dilute solution. These colloids are believed to act as catalysts for light energy, converting it into chemical energy in a reduction process similar to the first stage of synthesis of organic from inorganic substances in the green plant by the agency of chlorophyll. Such a synthesis

occurring in nature, they think, would probably constitute the first step in the origin of life.

Hemicellulose in roots, rhizomes, and tubers, A. STIEGER (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 86 (1913), No. 4, pp. 270-282).—The author details the results of examinations made on the subterranean parts of 15 plants. He found hemicelluloses in all, but was not able to settle the question as to whether these serve as structural or exclusively as reserve material. A bibliography is given.

Protoplasmic contractions resembling plasmolysis which are caused by pure distilled water, W. J. V. OSTERHOUT (*Bot. Gaz.*, 55 (1913), No. 6, pp. 446-451, figs. 6).—This amplifies a preliminary account already noted (*E. S. R.*, 29, p. 134) and gives some details of the study.

It is stated that in many cases contractions in young cells closely simulating true plasmolysis may take place with great rapidity on immersion in pure water, while older cells respond more slowly and show by alterations of their chromatophores that they are undergoing false plasmolysis. True and false plasmolysis may be produced simultaneously, these contractions usually becoming irreversible at a certain point. The effects observed for distilled water were also produced by that from ponds, rivers, and springs, and are therefore held not to be due to toxic products of distillation.

It is held that the cause of these phenomena is increased permeability of the plasma and internal cell membranes, as the result of which some or all of the osmotically active substances diffuse out. The protoplasm then shrinks as the result of the water loss from the vacuoles, this being often followed by apparent coagulation of the protoplasm, with most of the features characteristic of cytolysis in animal cells usually absent. Absorption of water as a cause is precluded by the fact that the cells do not increase in size. The increased permeability is held to be due to the loss of certain substances upon which the maintenance of normal permeability depends (the most important being the inorganic salts), which is followed by increased permeability of the cell membranes as measured by electrical means.

Toxic inorganic salts and acids as affecting plant growth, C. B. LIPMAN and F. H. WILSON (*Bot. Gaz.*, 55 (1913), No. 6, pp. 409-420).—Tabulated results are given of preliminary studies made on vetch and wheat as to the effects thereon of varying proportions in the soil of sulphuric acid and of its copper, zinc, and manganese salts, leading to the conclusion that the tolerance of plants for certain of the inorganic salts commonly regarded as very poisonous is much greater than we have been accustomed to believe. Some plants are said to be actually stimulated by quite considerable proportions of such salts. A further search for the limits of toxicity is in progress. The work is claimed to present new evidence regarding the stimulating effects of manganese sulphate on the growth of plants. Certain facts are thought to indicate that the soil flora is permanently modified by the treatment of the soil as herein outlined.

Arsenic compounds in agriculture and possible danger from their use, G. AMPOLA and G. TOMMASI (*Ann. R. Staz. Chim. Agr. Sper. Roma*, 2. ser., 5 (1911), pp. 263-277, pls. 2; *abs. in Centbl. Bakt. [etc.]*, 2. Abt., 38 (1913), No. 7-12, pp. 230, 231).—It was found that arsenic acid is injurious to green plants when present in nutritive solutions in concentrations not less than 1 mg. per liter of water. Bean plants died after 24 days in 3 mg. and maize after 27 days in 5 mg. per liter, lupines showing an intermediate degree of resistance, and no plants showing growth at a concentration of 20 mg. per liter.

In soil cultures the limits were more difficult to determine on account of absorption, but growth was usually checked at a concentration corresponding to 0.3 mg. of arsenic per kilogram of soil. The arsenic mostly went to the

leaves, but small proportions were found in the fleshy or juicy portions in the case of gourds, tomatoes, and beans when fresh, only traces being found in dried grains, peas, etc. Absorption of arsenic by soil is said to vary with the concentration and time and to be incomplete.

Arsenic was recovered from the soil under olive trees that had been sprayed therewith for olive fly. It is considered necessary to regulate the use of arsenic in such connection on account of possible injury therefrom.

Studies on the anatomical and physiological influence of tobacco smoke on seedlings, A. PURKYT (*Anz. K. Akad. Wiss. [Vienna], Math. Naturw. Kl., 1912, No. 17, p. 265; abs. in Centbl. Bakt. [etc.], 2. Abt., 38 (1913), No. 7-12, p. 211*).—The author reports that in tobacco smoke plants develop high turgor which is later gradually lost; that abnormal thickening of the stems is due to growth in the size but not in the number, of cells, which in case of the leaf epidermis is expressed in alterations of form, hypertrophy of stomata, and deformation of leaf hairs; and that along with other changes mentioned, the formation of both wood and bast fiber is limited by exposure to tobacco smoke.

Injuries to vegetation by furnace gases and ashes, H. C. MÜLLER ET AL. (*Ber. Agr. Chem. Kontroll u. Vers. Stat. Pflanzenkrank. Prov. Sachsen., 1912, pp. 19-22*).—A condensed and apparently preliminary account is given regarding the probable or actual injury done to vegetation in the neighborhood of certain furnaces, factories, etc., distributing smoke gases, ashes, and dust. An illustrative table is given showing that leaves and twigs of hawthorn in an exposed situation gave a considerable increase of the ash, chlorin, and sulphur content.

Effects of illuminating gas on vegetation, G. E. STONE (*Massachusetts Sta. Rpt. 1912, pt. 1, pp. 45-60, pls. 2*).—The author presents a general description of the effects of gas poisoning on trees and gives a number of specific examples of injurious as well as stimulating effects due to illuminating gas. The symptoms of gas poisoning are said to be best obtained from a careful examination of the wood at the base of the tree or the roots.

During the winter a break in a gas pipe led to the defoliation of a large number of plants in a short time. Those most severely injured were roses, geraniums, and abutilon, though others were also somewhat injured. The ferns, mosses, and liverworts near the gas inlet were scarcely affected. After being defoliated the geraniums and abutilon produced small leaves, and the leaves on the variegated abutilon which were put out were entirely green.

On Carolina poplars illuminating gas is said to show some characteristic effects. The symptoms of gas poisoning are generally a peculiar swelling and cracking of the bark, the lesions often extending for a foot or more along the trunk. On the sides of these cracks the bark was bulged out and examination showed a thick layer of soft parenchymatous tissue extending to the wood and apparently derived from the cambium zone. It is believed that the absorption of the gas may have killed the tissue exterior to the cambium layer before the cambium itself was affected, and that, in this way, the tension of the outer tissues being diminished, a stimulation of the cambium cells resulted.

When willow cuttings were grown in water charged with illuminating gas from time to time, there was found to be a slight acceleration in the development of all plants subjected to gas, although the gain was not very marked. The development of the lenticels and roots seemed to be considerably favored where the cuttings were placed in the gas-charged water.

Influence of a radio-active body on germination, J. CROCHETELLE (*Jour. Agr. Prat., n. ser., 26 (1913), No. 37, pp. 332, 333, fig. 1*).—The author gives a preliminary report of his experiments regarding the influence of radio-active substance on some common plants, stating that while the results obtained with different plants were not uniform, bean seedlings so treated showed a striking

acceleration of growth, which was more marked in cases where the radioactive powder was applied directly than where plants in tubes were exposed thereto.

Semipermeability of seed coats, C. A. SHULL (*Bot. Gaz.*, 56 (1913), No. 3, pp. 169-199, figs. 9).—The author gives an account of investigations carried on for two years regarding the character of the seed coat of *Xanthium*, with particular reference to the work of Becquerel (*E. S. R.*, 19, p. 426), Brown (*E. S. R.*, 18, p. 727), and Schroeder (*E. S. R.*, 25, p. 123), with conclusions substantially as follows:

The dry seed coats of *Xanthium* are impermeable to dry alcohol, ether, chloroform, and acetone. Becquerel's results with coats of other seeds are confirmed. No evidence of diffusion of oxygen through dry seed coats was obtained. Selective semipermeability independent of living substance was established for the seed coat of *Xanthium* (lists being given of substances admitted or excluded), which, it is said, may be removed and used as an osmotic membrane of superior quality. The outer layer of the testa can not so function, and the inner exceeds the middle layer in this respect, neither of these two being so efficient alone as before their separation. The middle coat contains more tannin than the inner, but the tannin does not exist in either as a continuous layer, and semipermeability is not destroyed by treatment with solvents of tannin. Semipermeability is said to have been demonstrated for the seed coats of plants in six widely separated families, membranes of many plants showing this property even when dead. It is said that the capillary and imbibition force of the embryo of *Xanthium* when the seed is air dry is about 965 atmospheres, and that an increase in the moisture of the embryo equal to 7 per cent of its air dry weight reduces the internal forces by 590 atmospheres. It is stated that the unusual intake of water noticed with some substances, especially with certain acids and alkalis, is due largely to the development of osmotically active substances inside the semipermeable membrane; also that some evidence was obtained unfavorable to Armstrong's hydrone theory of selective semipermeability (*E. S. R.*, 21, p. 126).

A bibliography is appended.

The influence of partial suppression of the reserve material in seeds upon the anatomy of plants, M. DELASSUS (*Compt. Rend. Acad. Sci. [Paris]*, 157 (1913), No. 3, pp. 228-230).—Reporting on an extension of studies already noted (*E. S. R.*, 26, p. 729), the author gives comparative results obtained, concluding that the effects of mutilation of cotyledons upon the anatomical structure of the young plants produced therefrom are marked, showing a retarded and diminished growth expressed by lowered development of the tissues, especially those concerned with support and protection.

The function of grape leaves in relation to the clusters, A. MARESCALCHI (*Staz. Sper. Agr. Ital.*, 45 (1912), No. 12, pp. 940-944).—Experimentation is said to have shown that grape clusters on defoliated shoots still form a considerable amount of sugar, also that while quite a proportion of acid is noted there is a deficiency as regards diffusible coloring matters.

Some points on the floral development of red clover, J. N. MARTIN (*Proc. Iowa Acad. Sci.*, 19 (1912), p. 129).—This is a brief discussion of the relative rates of development of different parts of the flower of red clover, the resulting inequalities observed, and the changing relations sustained. A more detailed account is to appear later.

Demonstrations of ectotrophic and endotrophic mycorrhiza, W. B. McDougall (*Rpt. Mich. Acad. Sci.*, 14 (1912), p. 45).—An abstract is given of a report on an investigation conducted to determine if possible the seasonal, physiological, and ecological relations of mycorrhiza.

On the shellbark hickory three forms of ectotrophic mycorrhiza were found. One of these is bright yellow in color, distinctly filamentous, and has numerous short branches extending into the soil. The second form is brown, the fungus mantle consisting of pseudoparenchyma such as is found in many lichens. The third form is whitish or nearly colorless, distinctly filamentous, but smooth on the outside.

On oaks the same variations in microscopic structure were found, but without the variations in color, all specimens collected being whitish. On larch a form was found in which the outer cells of the root cortex were pushed apart by the growth of mycelia between them. Endotrophic mycorrhiza were found in great abundance on maples, while on American linden the same fungus was found to be both ectotrophic and endotrophic.

Contributions on the colorless sulphur bacteria, G. HINZE (*Ber. Dent. Bot. Gesell.*, 31 (1913), No. 4, pp. 189-202, pl. 1).—The author studied two sulphur bacteria found in slime and mud in the Bay of Naples, one being already known as *Monas mülleri*, the other being considered as new and named *Thiovulum* n. gen.

Culture of micro-organisms, E. KÜSTER (*Kultur der Mikroorganismen. Leipzig and Berlin, 1913, 2. ed., rev. and enl., pp. 218, figs. 26*).—This is the second edition of a book previously noted (E. S. R., 19, p. 932).

FIELD CROPS.

Causes of the increased yields of agricultural crops during the last three decades, D. LEHN (*Illus. Landw. Ztg.*, 32 (1912), Nos. 69, pp. 627, 628; 70, pp. 636-638).—The author discusses the increased yields during the last three decades and attributes them to the increased intelligent use of commercial fertilizers, the introduction of better producing varieties, management systems, and methods of soil cultivation.

Making money on farm crops, F. B. NICHOLS (*St. Joseph, Mo., 1913, pp. 288, figs. 80*).—This book discusses soils for crops and the improvement of farm crops, with chapters on the production of alfalfa, clover, cowpeas, corn, wheat, oats, and the sorghums.

[Experiments with field crops] (*Abs. in Jour. Bd. Agr. [London], 19 (1913), Nos. 11, pp. 936-939; 12, pp. 1029-1031; 20 (1913), No. 1, pp. 42-47*).—Several abstracts are given of reports of locally conducted experiments in Great Britain with grasses, mangolds, wheat, barley, sugar beets, permanent pastures, potatoes, oats, peas, tobacco, millet, and Chinese alfalfa.

Field experiments (*Yorkshire Council Agr. Ed. and Univ. Leeds [Pamphlet] 85, 1912, pp. 2-36*).—In fertilizer experiments with meadow hay, the unmanured plats consisted chiefly of bent and sorrel. Barnyard manure applied each year seemed to encourage the growth of the better grasses, especially fox-tail and cocksfoot, and to repress bent. Applied in alternate years it apparently increased the growth of the desirable grasses, particularly golden oat grass. Using barnyard manure and complete artificials in alternate years encouraged foxtail and cocksfoot, golden oat grass, and tall oat grass, but the highest percentage of good grasses followed a complete mixture of artificials applied every year. With niter and superphosphate applied annually desirable grasses and also sorrel to a slight extent were fostered, while with nitrate of soda alone cocksfoot and tall oat grass thrived at the expense of bent, and with sulphate of ammonia alone cocksfoot thrived at the expense of foxtail and golden oat grass. Lime did not seem to increase the yield of hay but to suppress the growth of sorrel.

Plans of manurial experiments with pasture grasses, potatoes, and swedes are given.

[Field crop experiments], P. H. FOULKES (*Field Expts. Harper-Adams Agr. Col., and Staffordshire and Shropshire, Rpt. 1912, pp. 3-14, 21, pl. 1*).—In these experiments lime seemed to be of benefit to grass lands. Two and one-half cwt. of superphosphate and $\frac{1}{2}$ cwt. of sulphate of potash apparently gave better results than other fertilizers used, the yield being 39 cwt. 32 lbs. of hay per acre.

Variety tests with wheat, oats, swedes, mangels, and sugar beets are given in tabular form. The results of fertilizing with a radio-active substance containing silica 80.44, water and volatile organic matter 10.54, oxid of iron and alumina 2.20, total sulphuric acid 5.40, soluble phosphoric acid 1.37, and soluble salts and soluble free acids 3.32 per cent, with a trace of uranium, and applied with a commercial fertilizer at the rate of 2 per cent of the total application, were contradictory with swedes, but increased yields of from 2 to 4 tons per acre followed its use with mangels.

Forage crop trials are reported with alfalfa, sainfoin, wold grass, crimson clover, *Lathyrus sylvestris*, flax, and Heliantia. A Chinese alfalfa produced at the rate of 4 tons 1 cwt. per acre. Wold grass, cut June 13, yielded 10 tons 6 cwt. per acre, and flax yielded 520 lbs. seed and 26 cwt. fiber per acre.

Manurial experiments, G. BALFOUR and J. C. RUSHTON (*Field Expts. Harper-Adams Agr. Col., and Staffordshire and Shropshire, Rpt. 1912, pp. 46-58*).—Tabulated results are given of manurial experiments carried on at 11 centers with meadow hay, mangels, swedes, potatoes, sugar beets, and alfalfa. Basic slag, 500 lbs. per acre, in place of superphosphate (300 lbs.) seemed to check greatly the "potato disease." At one center 300 lbs. of barnyard manure per acre apparently produced increased yields with mangels.

Report of Hedemarken Experiment Station, 1912, W. CHRISTIE (*Ber. Hedemarkens Amts Forsöksstat. Virks., 8 (1912), pp. 59, pls. 3*).—Accounts of the following lines of investigations are given: Trials with seed potatoes of different sizes, with different distances of planting, and with whole and cut seed potatoes, 1908-1912; the starch content of samples of potatoes, 1912; trials with alfalfa, 1906-1911; farm manure and artificial fertilizers for turnips, 1907-1911; and top-dressing with artificial fertilizers for meadows, 1910-1912.

Report of Ribe County Western Agricultural Society, 1912, N. ESBJERG (*Ber. Ribe Amts Landbofor. Havebr. og Husmands., 1913, pp. 34*).—The experiments with shelter for agricultural crops, which were commenced in 1909 (*E. S. R., 28, p. 40*), were continued during 1912. The results obtained corroborated those previously reported, showing that shelter had a very beneficial influence on the growth of farm crops and increased the yields obtained in a marked degree. The planting and care of windbreaks and hedges which break the force of the wind therefore doubtless constitute a phase of profitable permanent farm improvements.

Report of the plant culture stations, 1912-13, H. C. LARSEN ET AL. (*Ber. Stat. Planteavl. [Denmark], 1912-13, pp. 150*).—A brief account of the organization and activities of the different Danish plant culture stations during the year.

Plant breeding at Tystofte, E. LINDHARD (*Tidsskr. Landbr. Planteavl, 20 (1913), No. 1, pp. 1-23, figs. 5*).—The paper gives the general principles followed in the plant breeding work done at this experiment station.

A method for variety tests, O. BILGER (*Illus. Landw. Ztg., 32 (1912), No. 91, pp. 827-829, figs. 3*).—This article discusses conditions arising from irregularities in soils and the need of multiplication of plats to reduce experimental error and secure comparative yields. A method of using 100 plats, 2.4 meters

square, in which 20 varieties were so arranged as to repeat each 5 times, is explained and illustrated. The use of the formula $\frac{\Sigma \pm d \cdot 0.845}{\sqrt{n(n-1)} \cdot \sqrt{n}}$ is explained in calculating the probable experimental error for these 20 plats. In this formula Σ = the sum of the yield of the repeated plats; d = the difference in yield from the mean; n = the number of plats, and 0.845 is a constant. By the use of this formula the author states that the probable error for each plat may be determined and so increase the accuracy and usefulness of the result of a test.

The influence of different vegetative factors on yield and counteracting relations of artificial factors added to the soil, E. A. MITSCHERLICH and R. FLOESS (*Landw. Jahrb.*, 43 (1913), No. 4, pp. 649-668, figs. 3).—In this article the authors discuss the law of minimum yield, the vegetative factors of light, soil temperature, and water, and the opposing influences of artificial vegetative factors in the way of fertilizers. It was noted that responsive energy was at its optimum in sunlight; that active energy in the roots was the result of soil temperature and favored increased yields; that loss of energy through increased root labor was a factor in decreasing yields; that the plant yield correlated with soil water subject to the law of minimum; and that yields were limited by the small quantity of soil water, but favored when this water was in the upper soil layer and when the plant food was such as to be soluble in the water during the entire vegetative period, so that the roots were relieved of heavy work.

Cereal investigations at the Nephi [Utah] substation, P. V. CARDON (*U. S. Dept. Agr. Bul.* 30, pp. 50, figs. 9).—This bulletin contains a report of the work of the substation, previously mentioned (*E. S. R.*, 23, p. 434), and includes a description of the substation and of the soil and climatic conditions that surround it. Tables give some meteorological data for the years 1898 to 1912, inclusive. The experimental work reported consists mainly of varietal and improvement tests of 68 varieties and strains of winter wheat, 1 of winter oats, 3 of winter barley, 2 of winter emmer, 10 of spring wheat, 7 of spring oats, and 14 of spring barley. Tables present data concerning yields, stand, dates of ripening, height, ratio of weight of grain to straw, and average weight per bushel of wheats and barleys, and the results of testing large, medium, small, and unseparated seeds of wheat planted at different distances in the row.

The results obtained show that "the winter varieties of all cereals have given better results than have the spring varieties. Of the winter wheat varieties, the hard red group has given the best yields. The soft white group, commonly grown in the Intermountain States, is comparatively low in yield. There seems to have been no definite correlation between stand and yield. The average date of heading and also the average date of ripening were about the same for all varieties. The average height of the winter wheats at Nephi during 1908 to 1912, inclusive, was 27 in. Approximately 1 lb. of grain was produced with every pound of straw.

"The average bushel weight for all varieties of winter wheat for the 5-year period was 61.4 lbs., or 1.4 lbs. above the standard weight. The average acre yield of spring wheats since 1908 is only 7.5 bu. for durum varieties and 8.9 bu. for common varieties, which is unprofitable in comparison with the acre yield of 17 to 23 bu. from winter wheats. Boswell winter oats have yielded very well in some seasons. In other seasons the yield has been low, thus reducing the average acre yield to 17.2 bu. for 1909 to 1912. However, the variety gives great promise as a winter oat for the intermountain region. The Black American, Giant Yellow, and Swedish Select varieties of spring oats have acre yields

of 15.2, 14.2, and 13.6 bu., respectively, in 1909 to 1912, inclusive. Two winter varieties of barley have given promising results. Of these 2, Utah Winter (C. I. No. 592) has yielded an average of 19.6 bu. per acre, as against 15.8 bu. for Tennessee Winter (C. I. No. 257). Three spring varieties were practically failures and were discarded in 1910. Black Winter emmer has shown itself adapted to conditions at Nephi, and probably will prove a valuable crop on the dry farms of the Mountain States. There was no apparent difference during 1912 between Buffum Improved Black Winter emmer (C. I. No. 3331) and the ordinary Black Winter emmer (C. I. No. 2337). . . .

"The following data obtained from the head rows are directly related to the results of the plat experiments: (1) The average winter survival of the cereals was about 65 per cent; (2) the tillering of the winter cereals varied with the thickness of the stand; (3) the average number of culms per plant in winter cereals seldom exceeded 25, though favored plants would sometimes have a greater number; (4) the average yields of the head rows gave the winter cereal varieties about the same rank as did the plat experiments; (5) the spring cereal varieties yielded less than the winter varieties, even though a better stand was obtained. . . .

"Some work has been done with grain sorghums, broom corn, millets, and prosos, but the results obtained have given little promise that these crops are adapted to the dry lands of the intermountain region.

"In the test of size of seed with both spring and winter varieties of wheat, the large seed was best in number of heads produced per plant and in yield per row. No great difference was observed among the different sizes of seed in the percentage of survival, plants maturing, or length of heads produced. In the test of different seed treatments for smut, the following points were observed: (1) The effect of the time of seeding on bunt depended largely on the season; (2) the best copper-sulphate treatment was 1 lb. of copper sulphate to 10 gal. of water, the seed soaked 10 minutes and dried; (3) the best formalin treatment was 2.5 parts of formalin to 1,000 parts of water, the seed soaked 10 minutes and kept moist 2 hours."

Prevention of lodging of cereals, ZIEHE (*Illus. Landw. Ztg.*, 32 (1912), No. 83, pp. 761, 762, figs. 3).—In a comparison with nitrogen and phosphorus, potash gave the best results in preventing lodging, due, it is believed, to the greater constitutional vigor of plants fertilized with this element.

The influence of moisture, fertilizer, and firmness of the soil on the root development of barley and wheat in early stages of growth, R. POLLE (*Über den Einfluss verschieden hohen Wassergehalts, verschiedener Düngung und Festigkeit des Bodens auf die Wurzelentwicklung des Weizens und der Gerste im ersten Vegetationsstadium. Inaug. Diss., Univ. Göttingen, 1910, pp. 84, pls. 2*).—The experiments here discussed were carried out in 2 sizes of pots of the Bücherhüllen form. Sixty-four pots had a height of 20 cm. and a width of 6 by 30 cm., and 32 were 40 cm. high and 6 by 20 cm. wide. Half of them were filled with clay soil and half with sandy soil. The low vessels each had 2 plants and the higher ones 1 plant each. To obtain more accurate results each treatment was repeated in 5 pots. Part of the pots were fertilized with 1/5 gm. nitrogen as nitrate of soda, 1/5 gm. P_2O_5 in $CaH_4(PO_3)_2$, and 1/5 gm. K_2O in 40 per cent potassium salt, and the sandy soil received 0.5 gm. calcium carbonate in addition. In a part of the pots the soil was carefully and uniformly packed in the case of both sandy and clay soils, and in the remainder the 2 kinds of soils were left in a loose condition. The barley was planted on June 11 and harvested from June 21 to 26. The wheat was planted on July 14 and harvested from July 22 to 28. A unique method is described of securing the roots in a normal position by means of pressing a board, provided with numer-

ous long needles set at right angles to its surface, into the soil of the pot containing the roots after one side of the pot had been removed.

This study was planned to throw light on the influence of fertilizer, moisture, and firmness of soil, on the amount of root growth, the length of roots, and the weight of above-ground parts, and the ratio between the root mass and the above-ground parts, in respect to clay and sandy soils with barley and wheat.

A clay soil, fertilized, showed a less length of root system in a dry condition (11.25 per cent moisture content) than in a moist condition (19 per cent moisture content), but a greater weight of root growth, whether loose or hard packed, fertilized or not, with both barley and wheat. Root growth was generally greater in the loose clay with barley, but compaction was more favorable with wheat. With wheat, the unfertilized clay soil produced greater root growth than the fertilized without regard to the moisture or compaction of soil.

With a sandy soil the root development was generally greater without the fertilizers, regardless of the degree of moisture or firmness of soil, with both barley and wheat, while in the presence of other factors firmness favored root development. In general, a greater root system was produced in the case of barley in a dry (5.4 per cent moisture content) sandy soil, whether loose or firm, fertilized or not. A dry sandy soil produced a better root system with wheat in a loose condition than when compact, without regard to the fertilizer application.

In general, with both barley and wheat 1 gm. of roots produced a larger amount of above-ground parts in both clay and sandy soil when fertilized than when not fertilized, in a moist soil than in a dry soil, and in a compact than in a loose soil.

A study of the variations in chemical composition of the timothy and wheat plants during growth and ripening, L. D. HAIGH (*Orig. Commun.* 8. *Internat. Cong. Appl. Chem.* [Washington and New York], 26 (1912), *Secs. VIa-XIb, App., pp. 115-117*).—This is an abstract giving the results found with timothy at 7 stages of growth and with wheat at 4 stages.

"The timothy plant takes up its plant food, nitrogen, and ash constituents at the most rapid rate in the young stages. It continues at a decreasing rate to absorb plant food during growth and in about the same rate as this growth proceeds. The percentage of moisture in the green plant is also the highest in the young stages. The heads of timothy increase in dry matter throughout the growth and ripening period. This increase includes all the plant constituents except potassium oxid, which had reached its maximum amount before the heads were collected for analysis. . . . Nitrogen-free extract increases at the greatest rate of all constituents. As the heads approach full ripening a noticeable increase of phosphorus pentoxid occurs. The stalks of the timothy increase in dry matter during growth and ripening; this dry matter added consists chiefly of crude fiber and nitrogen-free extract. Nitrogen, ether soluble material, potassium oxid, and phosphorus pentoxid increase during growth but decrease to some extent during ripening. The bulbs increase in dry matter throughout the growth period, but the amount becomes constant before ripening of the hay. The material stored up is principally nitrogenous matter and nitrogen-free extract. No starch is produced in the bulbs during the storing process. Potassium oxid is found in maximum amount in the first stage but phosphorus pentoxid tends to increase in amount as the plant matures.

"Large amounts of available potash and phosphoric acid are required for a good yield of timothy. Timothy would hardly prove a profit-yielding crop on soils other than those rich in potash, especially where the mineral elements would have to be supplied in the form of fertilizer.

"The wheat plant also takes up its principal plant food, nitrogenous and mineral matter, at the greatest rate in the young stages and at a decreasing rate as growth proceeds. The highest percentage of moisture in the green plant is found in the first series. The heads of the wheat gain more uniformly and rapidly in their amount of dry matter than any other part. Nitrogen-free extract is produced and stored at a greater rate than any other constituent, but nitrogen, ash, and ether soluble matter are added in some quantity also. Fiber is practically all formed by the time the blossom has fallen and remains constant to ripening.

"The wheat stalks contain their maximum amount of dry matter at blossoming time, after which they pass some of this material along to the ripening heads. Nitrogenous substance and nitrogen-free extract appear to be the constituents which the stalks yield up to the heads. The wheat roots and stubble increase in dry matter up to the milk stage, after which it decreases in amount, being passed along to the plant above ground. Fiber present in the roots does not decrease in amount but nitrogenous and ether soluble material, ash, and nitrogen-free extract pass out of the roots into the growing plant above ground during the ripening of the heads."

[Fibers from Papua (British New Guinea) and India] (*Bul. Imp. Inst. [Soc. Kensington]*, 10 (1912), No. 2, pp. 214-219).—This report includes analyses and valuations of cotton, sisal hemp, Sida fiber, *Sida rhombifolia*, and Indian jute.

The use of sulphur in the cultivation of turnips and beets, A. MAGNIEN (*Jour. Soc. Nat. Hort. France*, 4. ser., 14 (1913), Jan., pp. 54-56).—Experiments are here cited, in which sulphur scattered in the row at the rate of 2 to 3 gm. per meter at planting time apparently doubled the yields.

Bean growing in eastern Washington and Oregon, and northern Idaho, L. W. FLUHARTY (*U. S. Dept. Agr. Farmers' Bul.* 561, pp. 12, figs. 5).—This describes cultural methods, with suggestions on marketing, uses, and improvement of the crop.

Field trials on the manuring of carrots, E. E. STOKES (*Midland Agr. and Dairy Col. Bul.* 5, 1912-13, pp. 38-45).—It is concluded that "farmyard manure may profitably be supplemented with chemical fertilizers; salt applied to the description of soils generally used for the production of carrots is beneficial, especially in a dry, hot season; potash in some form is absolutely necessary, especially when dung is not so largely used; phosphates come next in order of importance; and the addition of nitrogenous manures may be advisable to promote a good start and early growth."

Clovers, M. CALVINO (*Estac. Agr. Cent. [Mexico] Bol.* 69, 1912, pp. 92, pls. 44).—This bulletin treats of the climate, soil, rotations, inoculation, fertilizers, cultivation, harvests, and methods of conserving the crop and silage in relation to the clovers *Trifolium pratense*, *T. repens*, *T. alexandrinum*, *T. soaveolens*, *T. incarnatum*, and *T. hybridum*. Various methods of rotation in which clovers are used as green manures are described.

Crimson clover, A. E. GRANTHAM (*New Jersey Stat. Circ.* 28, pp. 4).—This gives suggestions and directions for growing the crop under New Jersey conditions.

Effect of frost on corn, J. B. LINDSEY (*Massachusetts Sta. Rpt.* 1912, pt. 2, pp. 67, 68).—Chemical analysis of frosted corn revealed little new, excepting that the fiber percentage seemed to be larger than is usually the case. "In case the corn is intended for the silo, the quicker the crop is ensiled the better. If the crop is not to be ensiled, it may be allowed to stand uncut for a week or two."

Seed selection of Egyptian cotton, T. H. KEARNEY (*U. S. Dept. Agr. Bul.* 38, pp. 8).—In this bulletin the author discusses the importance of keeping the

stock pure and describes methods that may be employed by breeders whereby the purity of the seed may be maintained. It is believed that but one variety of cotton should be grown in a locality, that careful roguing should be practiced, and that growers' associations should arrange for pure seed production.

Nine titles of Bureau of Plant Industry publications on this subject are appended.

Propagating cotton plants by slips, G. GASTET (*Rev. Hort. Algérie*, 6 (1912), No. 5, pp. 144-148, figs. 4; abs. in *Internat. Inst. Agr. [Rome]*, *Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 10, pp. 2164, 2165).—A method by which herbaceous slips are pricked out in the hotbed or greenhouse is described in this article. The plants from which the slips are taken are removed from the field to the greenhouse late in the season, and profuse budding is induced.

Cowpeas for soil improvement, A. E. GRANTHAM (*New Jersey Stas. Circ.* 27, pp. 4).—This gives directions and suggestions for growing the crop under New Jersey conditions.

On the value of meadow foxtail grown on peat soils and the influence of the time of cutting, H. VON FEILITZEN, I. LUGNER and E. NYSTRÖM (*Svenska Mosskulturför. Tidskr.*, 27 (1913), No. 3, pp. 224-245).—Previously noted from another source (*E. S. R.*, 28, p. 834).

A variety test of potatoes, E. F. GASKILL (*Massachusetts Sta. Rpt.* 1912, pt. 2, pp. 11-16).—This paper contains brief notes on tests including 371 varieties during the past 18 years. The rate of yields ranged from 66 to 509 bu. per acre. It is noted that the majority of the new varieties are inferior to the old standard sorts, like Beauty of Hebron, Green Mountain, Early Rose, and Irish Cobbler, and that northern-grown seed was preferable to home-grown seed.

[**Field crop experiments**], G. T. MALTHOUSE (*Field Expts. Harper-Adams Agr. Col., and Staffordshire and Shropshire, Rpt.* 1912, pp. 17-19).—Results of variety tests of potatoes show yields as high as 6 tons 13½ cwt. per acre.

On the use of sulphur for the prevention of potato scab and as an indirect fertilizer, H. VON FEILITZEN (*K. Landtbr. Akad. Handl. och Tidskr.*, 52 (1913), No. 2, pp. 120-130).—Of the 5 varieties of potatoes experimented with during 1911, all but 1 yielded more on the plats receiving 400 kg. of sulphur per hectare (356 lbs. per acre) in addition to normal fertilizers than on those that did not receive sulphur, and the tubers were larger and better developed. Some improvements in regard to the appearance of scab were noted on these plats.

Trials with sulphur for horse beans and ray grass during 1912 are also reported. A bibliography on the subject of sulphur for plants is appended.

Lessons for American potato growers from German experiences, W. A. ORTON (*U. S. Dept. Agr. Bul.* 47, pp. 12).—The author discusses potato production as carried on in Germany, with special reference to conditions in this country.

It is noted that in Germany "the acreage is more than double that of the United States and the crop harvested more than 4 times our total. Of these potatoes 40 per cent are fed to stock, 28 per cent are used for table purposes, 12 per cent for seed, 6 per cent for alcohol, 4 per cent for starch and related products, and 10 per cent decay. The per capita consumption for food is 7.3 bu. per year in Germany, as compared with an estimate of 2.6 bu. in the United States. . . .

"We must hereafter produce enough potatoes to supply all our needs, as most sources of foreign imports have been closed by a plant-disease quarantine. To do this economically we should find a profitable outlet for a surplus production, . . . The most promising use for culls and surplus potatoes appears to be

in feeding hogs. There are possibilities in starch and alcohol and some hope of adapting the method of drying now used in Germany."

Beet sugar in New England, J. B. LINDSEY (*Massachusetts Sta. Rpt. 1912, pt. 2, pp. 69, 70*).—The author briefly reviews attempts to introduce sugar-beet culture in Massachusetts, and concludes "that while the climate is satisfactory and a considerable area is suited to the beet, economic conditions are not favorable to the production of beet sugar in Massachusetts."

Sugar-cane experiments, J. B. HARRISON and R. WARD (*Jour. Bd. Agr. Brit. Guiana, 6 (1913), No. 3, pp. 123-126*).—In a test with molasses as a fertilizer for sugar cane, only a slight increase could be detected from applications of 100, 200, and 300 gal. per acre. Partially sterilizing the soil of experimental plats with chlorinated lime applied at the rate of 150 lbs. per acre apparently gave slightly increased yields of cane over untreated plats.

Classification of the forms of *Helianthus annuus*, T. SAZYPEROW (*Trudy Bûro Prikl. Bot. (Bul. Angew. Bot.), 6 (1913), No. 2, pp. 95-110, figs. 3*).—Four forms are mentioned, viz, common, white, black, and armored sunflower. The last-named has a subepidermal layer of parenchyma cells which seem to be especially useful as a protection against the attacks of disease.

Research work at Harrow Experimental Station, 1911, W. A. BARNET (*Canada Dept. Agr., Tobacco Div. Bul. A14, 1912, pp. 20, pls. 2*).—This bulletin reports experiments in which different kinds of seed beds were established for tobacco.

The conditions point to the advisability of making up the bed 10 days before sowing, which was done at the rate of 1 teaspoonful (1/7 oz.) of seed to 70 sq. ft. To hasten the growth of seedlings a stock solution of 1/4 lb. of nitrate of soda to 2 gal. of water was made, one pint of which was diluted with 10 qt. of water for application.

Tests in curing in small and large kilns and fertilizer tests with bright tobacco were carried on. In a comparison between the bright tobacco and Burley, the Burley proved the more profitable. A description of a new curing barn is given.

Tobacco culture, G. N. BLACKSHAW (*Rhodesia Agr. Jour., 10 (1912), No. 1, pp. 56-66, pls. 5*).—In this article methods of preparing the soil are given, these including the burning of the soil to a depth of 1/2 in. As a remedy for cutworms a poison is suggested which consists of 1 lb. arsenite of soda, 8 lbs. brown sugar, and 10 gal. of water; this is to be mixed with green stuff or corn meal and distributed over the ground a few days before the tobacco is transplanted. Broadcasting or drilling the fertilizer in the soil before the plants are set is advised, as compared with top-dressing later.

Suggestions for gathering and storing the seed and directions for growing, curing, storing, and baling Turkish tobacco are given.

Cultivation of tobacco for the preparation of fruit and hop washes (*Jour. Bd. Agr. [London], 19 (1913), No. 12, pp. 985-994*).—This article discusses the difference between smoking tobacco and that used for the extraction of nicotin. It is stated that the latter should be of rank, coarse-growing varieties unfit for smoking purposes. Methods of cultivating, fertilizing, harvesting, extracting, and preparing the washes are discussed. The cost and returns per acre are given. In Kent in 1911 yields of over 2,000 lbs. of dry leaves, with over 150 lbs. of nicotin, per acre were obtained.

A cross between *Triticum vulgare* and *T. monococcum*, N. WAWILOFF (*Trudy Bûro Prikl. Bot. (Bul. Angew. Bot.), 6 (1913), No. 1, pp. 1-19, pl. 1, fig. 1*).—The chief characteristics of this cross were observed to have been lateness in ripening and sterility.

Wheat growing in Wisconsin, E. J. DELWICHE and B. D. LEITH (*Wisconsin Sta. Bul.* 233, pp. 3-22, figs. 8).—This bulletin outlines briefly the present status of wheat growing in Wisconsin, and includes reports on results of experiments which for six successive seasons have been carried on at the station at Madison and at the substations in the different sections of the State. In this connection are discussed the cause of the decline in wheat growing in Wisconsin, the present outlook, and wheat and soil depletion. Under essentials of wheat culture are discussed rotations, soil preparation, good seed, time and manner of seeding, harvesting and threshing, and spring and winter wheat.

Tabulated data of variety tests of both winter and spring wheats are given, including nearly 30 selections. In general, winter wheat outyielded spring wheat.

Some variable results of seed testing, G. E. STONE (*Massachusetts Sta. Rpt.* 1912, pt. 2, pp. 22-30).—This paper gives results of purity and germination tests made at about 20 different seed-testing stations of seed taken from the same bulk, and discusses the difficulties underlying the identification of seeds. The seeds used were red clover, timothy, Kentucky blue grass, orchard grass, millet, and alfalfa. Wide variations were obtained from the various stations. The germination of Kentucky blue grass was reported at from 3 to 88 per cent, and orchard grass showed a range of 45 per cent.

Seed work for the year 1912, G. E. STONE (*Massachusetts Sta. Rpt.* 1912, pt. 2, pp. 17-21).—This gives results with 285 samples for germination and 82 samples for purity tests. A total of 1,517 lbs. seed was separated. The seeds tested for purity were of unusually high grade.

"Yellow rattle," as a weed on arable land, WINIFRED E. BRENCHEY (*Jour. Bd. Agr.* [London], 19 (1913), No. 12, pp. 1005-1009, figs. 2).—Two distinct species of this parasite are noted, *Rhinanthus minor* and *R. major*. Their life history, means of attaching to cultivated crops, especially grasses and cereals, and the method of combating, which consists chiefly of fallow cultivation for a season, are discussed.

HORTICULTURE.

Intensive farming, L. C. CORBETT (*New York, 1913, pp. 146+IV, pls. 8, figs. 3*).—This comprises a popular handbook of information on the fundamental practices employed in various types of intensive farming. The subject matter is discussed under the following general headings: The problem, vegetable growing, onions, celery, frame culture, the vegetable forcing industry, fruit growing, small fruits, the citrus industry, plant breeding as a factor in intensive farming, seed growing, the nursery an example of intensive crop production, irrigation, animal industry, economics of intensive industries, and the cropping system as a unit.

Recent progress in Belgian horticulture, VERNIEUWE (*Internat. Inst. Agr.* [Rome], *Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 9, pp. 1321-1326).—In this paper the author briefly reviews the recent developments in Belgian horticulture, including the measures employed to maintain and safeguard the interests of the horticultural industry.

Malnutrition or overfertilization of greenhouse crops, H. D. HASKINS (*Massachusetts Sta. Rpt.* 1912, pt. 2, pp. 71-79).—An analytic study of greenhouse soils in which cucumbers and sweet peas made sickly growth leads the author to conclude that imperfect growth and development were due in these cases, as well as in many other cases where plant growth is unsatisfactory, to an annual accumulation of soluble plant food rather than to fungi and bacteria. With cucumbers the trouble does not usually develop until the third year

after the soil has been placed in the houses. The plants which at first are usually very vigorous turn yellow prematurely and fail to develop fruit.

The author emphasizes the importance of good drainage in greenhouse beds and benches. Wherever indications of overfertilization appear the soil should be leached out with hot water as soon as the crop is removed. The crop may sometimes be saved by applying about 3 in. of fresh loam to the surface of the bed and working lightly around the plants. This promotes the formation of new roots. After the removal of the crop from one-third to one-half of the soil in the benches should be replaced with new loam before replanting.

The influence of various light intensities and soil moisture on the growth of cucumbers, and their susceptibility to burning from hydrocyanic acid gas, G. E. STONE (*Massachusetts Sta. Rpt. 1912, pt. 1, pp. 61-72, pl. 1*).—The experiments here reported were conducted at the station by F. L. Thomas with cucumber plants which were grown in the greenhouse under varying light and soil moisture conditions alongside plants growing under normal conditions. After the plants had reached a certain degree of development they were all submitted to the same normal hydrocyanic acid gas fumigation.

Summarizing the data relative to light conditions, the greatest average height of the plants and length of internodes were found in the series where the light was less, while, on the other hand, the shortest internodes and greatest diameter of the stems occurred in those plants which received the most light. The average length and width of leaf was variable but the plants grown where the light was excluded had the largest leaves. It is suggested that the production of larger leaves under certain light intensities is apparently a response to a demand for greater carbon assimilation. In the soil moisture experiments the average height of the plants was greater and the leaves larger in the pots containing the largest percentage of water. Within certain limits the diameter of the stems and length of the leaf petioles and internodes was also greater in the plants growing in a higher percentage of soil moisture; in pots containing as high as 70 per cent of water there was too much water for the best development.

Burning from hydrocyanic acid gas was more extensive on plants grown under a poor light and excessive moisture conditions than where the light and moisture conditions were good, showing that burning by fumigation is induced by a difference in the development of the tissues whether brought about by inferior light conditions or excessive moisture. Further experiments are being conducted to throw more light on the influence of other factors on burning.

Some effects of fertilizers on the growth and composition of asparagus roots, F. W. MORSE (*Massachusetts Sta. Rpt. 1912, pt. 1, pp. 154-167*).—The experiments here reported have been noted from another source (*E. S. R.*, 28, p. 236).

The inheritance of blossom color in beans, J. K. SHAW (*Massachusetts Sta. Rpt. 1912, pt. 1, pp. 182-203, pl. 1*).—The author here presents and discusses a series of tables which show the inheritance of blossom color in various combinations of some 19 varieties of garden beans, the progeny from the crosses having been self-fertilized through four generations. An interpretation of the results relative to blossom color is to be made later through an analysis of the records of the inheritance of seed-coat color.

Report of cranberry substation for 1912, H. J. FRANKLIN (*Massachusetts Sta. Rpt. 1912, pt. 1, pp. 209-234*).—A progress report on the experiments conducted and observations made at the cranberry substation during the year (*E. S. R.*, 28, p. 341). The subject matter is discussed under the following general headings: Weather observations, frost protection, fungus diseases, varieties, blossom pollination, fertilizers, insects (see p. 154), and miscellaneous.

Progress in determining the local conditions which indicate frost is reported, the season's records indicating that the early evening dew point can be relied upon to a considerable extent in forecasting minimum temperatures on the bogs. The use of oil heaters was found to be effective as protection against frost, but was too expensive to be practicable.

In the work with fungus diseases being conducted in cooperation with the U. S. Department of Agriculture five plats each 4 rods square received two sprayings of Bordeaux mixture and one of neutral copper acetate. Two lbs. of resin fish-oil soap were used with the Bordeaux in all cases and with the acetate. As compared with the check plats increased yields of from 45 to 144 per cent were secured on the sprayed plats. During the previous year the sprayed plats showed no increase in quantity of fruit over their checks, hence it is suggested that the effects of annual spraying may be cumulative. When the fruit was gathered no distinct difference in color between the berries from the sprayed plats and their checks was observed, but differences in the size of the berries appeared to be influenced by the time of picking. In early pickings the berries on the check plats were larger, whereas in the last pickings the berries on the sprayed plats were larger. It is suggested that this was due to a retardation in the development of the fruit on the sprayed vines due to the heavier crop which they were producing. The keeping quality was improved by spraying, although this was more marked with the Howe variety. This and the distinctly greater increase in quantity of fruit on the Howe plats indicate the presence of a special diseased condition affecting that variety more seriously than the others. This disease, hitherto undetermined, has been tentatively called "blossom end rot." Its characteristic effect on the fruit is to cause it to rot, beginning at the blossom end and working gradually toward the stem end, the berry becoming soft, but remaining plump and watery, as the decay progresses. The tests appeared to give no evidence that the stage of ripeness at which the berries were picked had any effect on their keeping quality. Observations made during the past two years seem to indicate that resanding favors fungus diseases and that spring sanding favors fungus development more than does fall sanding.

The pollination experiments as continued on another part of the bog (E. S. R., 26, p. 841) appeared to contradict partially the results previously secured, inasmuch as the area over which the bees were excluded bore at least half a crop of berries. The experiment is to be repeated.

Observations made during the year indicate that the berries of a heavy cranberry crop will, other conditions being equal, keep better than those of a light crop, and that the surface roughening of the fruit in certain varieties may be relied upon to some extent as an indicator of their keeping quality.

The results of storage tests which were carried out with berries from all the fertilizer plats gave no evidence that any of the fertilizers, except perhaps the acid phosphate, had affected the keeping quality. Nitrate of soda had a marked effect in increasing the quantity of fruit, although the variation in size between the berries from the different plats was not very great. Potash caused no increase in fruit and the phosphate but very little. If lime had any effect, it was detrimental. The vines on the plats to which nitrate was applied made a more luxuriant but desirable growth than those on the rest of the bog.

New varieties of fruits, A. NOMBLOT (IV. *Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, pp. 464-468*).—With the view of procuring new varieties of tree fruits sowings of seed from different varieties were made a number of years ago. Consideration is here given to those forms which have arisen from naturally fertilized fruits.

The results with the cherry have shown that certain types, as the Bigarreau, Morello, Black Heart, etc., possess some degree of fixity. The Mirabelle and Green Gage plums and a number of peaches have also proved to be relatively fixed. In the case of apples and pears many forms varying in their vegetative characters and not resembling the maternal parent have been obtained.

The author is not inclined to favor grafting as a means of hastening the fruiting period of seedling trees since this method has not given conclusive results. Moreover, he does not favor the propagation of varieties by the use of immature wood.

Crew work, costs, and returns in commercial orcharding in West Virginia, J. H. ARNOLD (*U. S. Dept. Agr. Bul. 29, pp. 24, figs. 5*).—In this bulletin the author summarizes and analyzes the experiences in orchard management of different individuals who have been pioneers in the development of the peach industry in the drainage basin of the Potomac River in West Virginia. Practically every factor involved in peach growing is considered with special reference to the determination of costs.

From an analysis of the data secured the author comes to the general conclusion that with the most favorable conditions that can be reasonably expected and under the most skillful and experienced management, average dividends of over 25 per cent are practically impossible. At the average price of 65 cts. per basket a good manager might reasonably expect to pay 10 per cent dividends on the money invested.

Cultivation and exploitation of the avocado, G. R. VALENCIA (*Estac. Agr. Cent. [Mexico] Bol. 71, 1912, pp. 70, pls. 20*).—A popular treatise on the botany, culture, exploitation, and uses of the avocado.

Mulberry and fig culture, M. CALVINO (*Estac. Agr. Cent. [Mexico] Bol. 73, 1912, pp. 33, pls. 8*).—A popular cultural treatise with special reference to Mexican conditions.

On some hybrids of *Vitis vinifera* and *V. berlandieri*, GARD (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, pp. 395, 396*).—In studying a number of hybrid forms of *V. berlandieri* × *V. vinifera* raised from seed of *V. berlandieri* it was observed with regard to the stem that the hairy character of the maternal parent and also the glabrous character of most varieties of *V. vinifera* occurred among the hybrids, together with a large number of intermediate forms. Transverse sections of the stem show that the structure is sometimes intermediate between the two parents and sometimes nearer that of *V. vinifera*. Most generally certain characters of the liber and of the secondary wood, and especially those of the primary wood, are nearer *V. vinifera*. In the roots, on the other hand, these characters are nearer the other parent and are in accordance with the power of resistance to phylloxera and the excellent qualities as stocks possessed by these hybrids.

On the use of seedling vines as scions, TRABUT (*Prog. Agr. et Vit. (Ed. l'Est-Centre), 34 (1913), No. 46, pp. 625, 626, figs. 2*).—The author here calls attention to some successful results secured during the past season in cleft grafting grape seedlings on green shoots of old vines. At the beginning of June young plants which had only their cotyledons were trimmed like ordinary scions and inserted on the top of green shoots. The end of the shoot was wrapped with a small band of paraffin paper secured with raffia. The completed graft was then covered with a small paraffined paper bag in order to preserve the humidity. The parts united in about 2 weeks' time after which the young plants grew vigorously. By October the union was hardly visible and the shoot was about 3 meters long.

The application of this method for the rapid propagation of new varieties is suggested.

The reconstruction of vineyards without grafting, C. OBERLIN (*Weinbau u. Weinhandel*, 31 (1913), Nos. 28, pp. 287, 288; 29, p. 297; 30, pp. 307, 308; 31, pp. 317, 318; 32, pp. 327, 328; 33, pp. 337, 338; 34, p. 347).—After a general survey of the results secured in reconstituting phylloxera infested vineyards in Europe the author concludes in substance that, although the use of American grape stocks may be the best means of reconstituting the vineyards in the warmer parts of Europe, the use of grafted vines is too costly and complicated a process for cold climate regions such as Alsace-Lorraine, where it is necessary to plant the grape sufficiently deep to protect the grafts from frosts. He calls attention to the relative resistance of grapes grown by the cordon system to phylloxera as compared with grapes grown on individual stakes, as well as the greater ease with which cultural and spraying treatments may be given. With special reference to the industry in Alsace-Lorraine he suggests that the double arm cordon system be adopted and attention also given to the testing of direct-bearing American-European hybrids which are much more frost resistant than the grafted stocks.

Some new or little-known Philippine economics, O. W. BARRETT (*Philippine Agr. Rev. [English Ed.]*, 6 (1913), No. 10, pp. 493-503, pls. 10).—Brief descriptions are given of a large number of native fruits and plants of more or less economic importance.

The Kafir orange, D. FAIRCHILD (*Amer. Breeders Mag.*, 4 (1913), No. 3, pp. 148-153, figs. 2).—Attention is here called to the Kafir orange (*Strychnos spinosa*), an edible member of the strychnin producing genus which has been successfully grown in Florida and southern California. Notes are also given on other species of this genus which promise to succeed in our semitropical regions and which with a little improvement through hybridization and selection may offer a number of unique fruits to American growers.

American medicinal flowers, fruits, and seeds, ALICE HENKEL (*U. S. Dept. Agr. Bul.* 26, pp. 16, figs. 12).—This bulletin describes the following 13 plants, the flowers, fruits, or seeds of which are in greatest demand for medicinal purposes: Juniper (*Juniperus communis*), saw palmetto (*Serenoa serrulata*), wormseed (*Chenopodium anthelminticum*), pokeweed (*Phytolacca americana*), black mustard (*Brassica nigra*), white mustard (*Sinapis alba*), raspberries (*Rubus occidentalis* and *R. strigosus*), prickly ash (*Zanthoxylum americanum* and *Z. clava-herculis*), smooth sumac (*Rhus glabra*), American linden (*Tilia americana*), poison hemlock (*Conium maculatum*), jimson weed (*Datura stramonium*), mullein (*Verbascum thapsus*), and elder (*Sambucus canadensis*).

Each plant is discussed with reference to its synonymy, habitat and range, description, collection, uses, and prices. Brief suggestions are given relative to the collection of flowers, fruits, and seeds.

Experiments in bulb growing at the United States Bulb Garden at Bellingham, P. H. DORSETT (*U. S. Dept. Agr. Bul.* 28, pp. 21, figs. 21).—In 1908 the Bureau of Plant Industry established an experimental bulb garden at Bellingham, Wash., to determine the feasibility of growing the so-called "Dutch bulbs," including hyacinths, narcissuses, and tulips in the United States. This bulletin reports the progress and present status of the work, including the cultural practices thus far employed.

Generally speaking the results have been satisfactory, a high grade of bulbs having been produced. On the other hand, the Department is not prepared to recommend the commercial culture of "Dutch bulbs" in this country until further information is gained relative to climatic and soil requirements, cultural practices, and methods of harvesting, curing, storing, transporting, and marketing the crop.

Weed extermination, G. E. STONE (*Massachusetts Sta. Rpt. 1912, pt. 2, pp. 35-40, pls. 3*).—In this article the author discusses different methods of exterminating weeds from lawns. Descriptions of devices for applying arsenate of soda, cutting weeds, and spreading fertilizer are included.

Legislation against the diseases and pests of cultivated plants in Ceylon, T. PETCH (*Dept. Agr. Ceylon Bul. 6, 1913, pp. 79-93*).—This bulletin contains the text of regulations which have been issued in Ceylon under ordinances enacted for the control of native diseases and pests and for preventing the introduction of others.

FORESTRY.

Forest valuation, F. RIEBEL (*Waldwertrechnung. Vienna and Leipsic, 1912, 2. ed., rev. and enl., pp. XVI+527, pls. 2*).—Part 1 of this work comprises a theoretical discussion of various factors which enter into the determination of the money value of a forest or a forest enterprise, consideration being given to the general economic, forest economic, and mathematical fundamental principles of forestry, and to the various methods of forest valuation. In part 2 the application of the theoretical knowledge relative to forest valuation to existing cases is illustrated by numerous examples.

An economic study of acacias, C. H. SHINN (*U. S. Dept. Agr. Bul. 9, pp. 38, pls. 11*).—In this bulletin the author discusses the economic importance of the leading acacias in various countries with the idea of bringing about more general planting in suitable regions in this country.

A study of the cultural requirements of the many species of acacia which have been grown as ornamentals in this country, chiefly in California, leads to the general conclusion that plantations properly located and managed are as likely to prosper in America as in other countries, where the various species have been a valuable source of tanbark, gums, timber, etc. Attention is called to the fact, however, that thus far our knowledge relative to the success of acacias in this country is chiefly of a cultural nature. It is yet to be determined whether the trees can be produced under close-planted commercial conditions and whether the products can be harvested and marketed in competition with those produced cheaply abroad.

Manihot caoutchouc, A. ZIMMERMANN (*Der Manihot-Kautschuk. Jena, 1913, pp. XI+342, figs. 151*).—A treatise on the culture, exploitation, and preparation of the various Manihot rubbers. Other rubber-yielding species are considered in as far as the practices employed in handling them are of value for the culture of the Manihot species. The subject matter is based partially on a review of the literature of the subject and partially upon observations made in German East Africa, as well as on the author's personal investigations.

An extensive bibliography of the subject is appended.

Device for planting white pine seed, G. E. STONE (*Massachusetts Sta. Rpt. 1912, pt. 2, pp. 31, 32, pl. 1*).—The device here described consists of a hollow iron tube about $\frac{5}{8}$ in. in diameter at the top of which is a funnel and to the bottom of which is attached a bent piece of strap iron about $1\frac{3}{4}$ in. in width and thick enough to give the required rigidity. This is sharpened at the end like a chisel. The hollow handle is extended by means of a rubber tube so that when the blade is thrust into the ground the opening comes over the hole which is made when the handle is brought to a vertical position. The seed is planted by dropping it into the funnel at the top of the handle.

Condition of experimental telegraph poles, treated and untreated, after eight years' service, C. H. TEESDALE (*Engin. News, 70 (1913), No. 22, pp. 1084-1086, figs. 4*).—The work here reported was started in the summer of 1905,

when a large number of treated and untreated chestnut and white cedar poles were set up in experimental lines in cooperation with the American Telegraph and Telephone Company. The previous results of this test have been noted (E. S. R., 25, p. 344). In the present report an outline is given of the experimental treatments, together with the results secured after a test of 8 years.

As a result of this experiment it appears that the average life of the untreated seasoned and green southern white cedar poles in this line will not exceed 7 to 8 years. Seasoned poles set untreated showed a larger percentage of removals than the green poles. This is attributed to the length of time the seasoned poles were held before they were set. The chestnut poles were found to be in a much better condition than the cedar. Some 63 per cent of the untreated poles were still only slightly decayed, while of the treated poles, excluding tar coating, 91 per cent were either sound or only slightly decayed. Good results were obtained with all preservatives, except tar. Coal-tar products gave better results than wood-tar products. The results obtained with the carbolineums were only slightly better than with coal-tar creosote. The southern white cedar poles brush-treated with good preservatives showed less decay than untreated chestnut poles but were decayed more than the treated chestnut poles. Fewer removals and fewer badly decayed poles were found in the portions of the line running through swamps and wet locations than in dryer situations. The worst conditions were found in cultivated fields and dry sandy situations.

The author concludes that, although brush treatments with a good preservative gave an increased life to poles sufficient to pay well for the cost of treatment, to be really effective the application should be sufficient to treat all the sapwood and in the case of chestnut probably some of the heartwood.

DISEASES OF PLANTS.

An outline of some of the topics covered by the department of vegetable physiology and pathology since its inception, G. E. STONE (Massachusetts Sta. Rpt. 1912, pt. 1, pp. 97-101).—A bibliography of the more important papers published by the department since 1888 is given.

Diseases more or less common during the year, G. E. STONE (Massachusetts Sta. Rpt. 1912, pt. 1, pp. 38-40).—Brief notes are given on winterkilling of twigs and roots of apple trees and the occurrence of scab (*Fusicladium dendriticum*), apple fruit rots, bitter rot (*Glucosporium fructigenum*), and of white pine blister rust on currants. A large number of other diseases due to parasitic fungi are listed. In addition notes are given on some forest and shade tree troubles, among them a mottling of chestnut leaves, the killing back of twigs of elm, maple, ash, butternut, Norway spruce, and sycamore, root diseases of elm, maple, and oak, as well as winter injury to other species. It is stated that the winter of 1912 was one of the worst on record for the depth of freezing and that vegetation in general was in poor condition owing to drought.

Work of the botanical research laboratory and of the laboratory for plant diseases at Klosterneuburg, L. LINSBAUER, J. K. SCHECHNER, and F. ZWEIFELT (Programm u. Jahresber. K. K. Höh. Lehranst. Wein u. Obstbau Klosterneuburg, 1911-12, pp. 141-166, figs. 6; Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 4 (1913), No. 7, pp. 1114, 1115).—The first article noted herein is the regular report regarding observations made on various diseases of orchard and small fruits, grapes, vegetables, etc., and of studies on some physiological problems, a list of addresses and publications being appended. The second article noted is a short and more specific account, by Linsbauer, of some physiological investigations bearing upon the development and some

physiological aspects of certain grape diseases, including *Plasmopara*, *Pseudo-pieziza tracheiphila*, and "Droah."

Studies of plant diseases, H. C. MÜLLER, E. MOLZ, and D. MORGENTHAUER (*Ber. Agr. Chem. Kontroll u. Vers. Stat. Pflanzenkrank. Prov. Sachsen., 1912*, pp. 67-76).—This is a condensed report on studies carried out on various diseases of grains, beets, potatoes, fruit trees, and garden vegetables, with a list of remedies and apparatus for their application tested and approved by the station.

Notes on *Cronartium coleosporioides* and *C. filamentosum*, E. P. MEINECKE (*Phytopathology, 3 (1913), No. 3, pp. 167, 168*).—The author reports the successful infection of *Castilleja miniata* with aecidiospores of *Peridermium stactiforme* from *Pinus contorta*.

Mosaic and allied diseases, with especial reference to tobacco and tomatoes, G. H. CHAPMAN (*Massachusetts Sta. Rpt. 1912, pt. 2, pp. 41-51*).—A report is given of observations on this disease of tobacco and tomatoes which the author says he has been able to produce on other plants, such as ragweed, jimson weed, etc.

The disease is held to be of physiological origin and is caused by the excessive activity of the oxidase and peroxidase enzymes in the plant and the partial loss of function of catalase. It is not considered due to any one enzyme alone nor to any special virus. It is infectious but not contagious, and does not occur in seed beds when new soil is used nor in properly sterilized seed beds.

Directions are given for the handling of the seed beds, the use of fertilizers, the choice of soils, etc., to reduce as much as possible the occurrence of this trouble. A bibliography is appended.

Cucumber and tomato canker (*Gard. Chron., 3. ser., 54 (1913), No. 1393, pp. 167, 168, fig. 1*).—This disease, due to *Mycosphaerella citrullina*, the same fungus which attacks muskmelons in the United States (E. S. R., 21, p. 148), is said to be widely spread in Great Britain, where it is causing considerable loss to tomatoes and cucumbers grown under glass, and it has recently been shown to occur on fruits of tomatoes grown in the open (E. S. R., 29, p. 847).

The fungus appears to be a wound parasite and is spread most rapidly by the pycnidiospores. On the tomato the symptoms which have been most frequently seen are the wilting of the whole or top part of the plant, and the appearance of brown sunken areas on some parts of the stem. These are generally within 1 or 2 in. of the soil, although in some instances the canker may be found farther up the stem.

Comparatively little is known regarding methods of prevention, but attention to the proper temperature and humidity of the houses and spraying with Bordeaux mixture, it is thought, would tend to prevent the serious occurrence of the trouble.

White-heads or take-all of wheat and oats (*Bd. Agr. and Fisheries [London], Leaflet 273, 1913, pp. 4, fig. 1*).—A brief description of this disease, *Ophiobolus graminis*, in its different aspects is given with a discussion of its prevalence, mode of attack, and prevention. It is said to flourish also on couch grass, *Bromus sterilis*, etc., requiring their suppression or control; likewise it is said to attack oats, rendering this crop unfit for rotation as a means of starving out the fungus. Blindness or abortion of the grain in the ear may be due to other causes named, but such cases may be recognized by the absence of the characteristic blackening at the base of the stem.

It is claimed that superphosphate of lime at the rate of 1½ cwt. per acre applied when the crop is young proved effective at Kew, and that in Australia iron sulphate at the rate of 1 cwt. per acre checked this disease.

The barberry and its relation to black rust of grain, H. T. GÜSSOW (*Phytopathology*, 3 (1913), No. 3, pp. 178, 179).—Attention is called to a report on the disappearance of *Puccinia graminis* in Denmark following the application of the law relating to the destruction of barberries.

The action of different luminous radiations on the formation of conidia on Botrytis cinerea, F. and MME. F. MOREAU (*Bul. Soc. Bot. France*, 60 (1913), No. 2-3, pp. 80-83).—The authors, studying the development of *B. cinerea* on carrot under a pure strong spectrum, found that conidia were formed under these circumstances only in the violet-blue portion of the spectrum. This result agreed with that obtained by Reidemeister (E. S. R., 23, p. 48), but disagreed with that reported by some other authors named.

A bacterial rot of cucumbers, O. F. BURGER (*Phytopathology*, 3 (1913), No. 3, pp. 169, 170).—A brief report is given of two years' investigations of a bacterial disease of the leaves and fruit of cucumbers.

On the fruit watery spots with brown centers appear, and later the cucumbers become soft and translucent. The first indication of infection on the leaves is shown by the presence of watery spots. Cultures made from the material showed the presence of a bacterium, and inoculation experiments demonstrated that this organism was the cause of the trouble.

Vines were reported as drying up without setting fruit, and this led to inoculation experiments on healthy flowers. These were found to turn yellow, blacken, and dry up without developing any fruit.

The cultural characteristics of the organism, which is a species of *Pseudomonas*, are being investigated further.

Corynespora leaf spot of cucumbers, W. GROSSER (*Illus. Schles. Monatschr. Obst. Gemüse u. Gartenbau*, 2 (1913), No. 8, p. 137).—A discussion is given of a disease of cucumbers said to cause great damage in England, but heretofore only sporadic in Germany, and attributed to *C. maei*.

In the absence of complete investigations as regards efficient and inexpensive means of control, the author recommends soaking the seed 4 hours in 0.5 per cent formalin solution before planting, also spraying the plant with 0.4 per cent Bordeaux mixture, as preventive measures. No remedy is offered as effective after the general outbreak of the disease.

Fusarium or Verticillium on okra in North Carolina? G. W. WILSON (*Phytopathology*, 3 (1913), No. 3, pp. 183-185).—In a previous publication (E. S. R., 26, p. 844), a disease of okra attributed to *F. vasinfectum* was described. Later the identity of the fungus had been questioned, and the author reports somewhat more in detail upon the disease and its causal organism. The studies are said to show that the fungus was not a *Verticillium* but a *Fusarium*, as previously reported.

Black heart of potatoes, E. T. BARTHOLOMEW (*Phytopathology*, 3 (1913), No. 3, pp. 180-182, pl. 1).—The attention of the department of plant pathology of the Wisconsin Station has been called to a blackening of the tissues of potatoes. An examination of these tissues showed them to be sterile. Following this a laboratory experiment was conducted, and it was found possible to produce the condition if potatoes were taken from the storage cellar and exposed to a temperature of from 38 to 45° C. (98.4 to 113° F.) for from 18 to 48 hours. The blackening did not develop to the same extent in all the potatoes. The change apparently begins in the center and radiates toward the margin, and if the abnormal potatoes are allowed to remain 10 days or 2 weeks before cutting, the blackened tissues in the center shrink, leaving a hollow with a black lining.

Further studies are being made on the physiological changes which cause the blackening, and for the present attention is directed to the disease and the importance of keeping potatoes at a uniformly low temperature.

Experiments relating to the control of potato scab, G. E. STONE and G. H. CHAPMAN (*Massachusetts Sta. Rpt. 1912, pt. 1, pp. 84-96, pl. 1*).—The results of experiments with various chemicals for the prevention of potato scab are given. These experiments were begun in 1908 and continued for 4 years, different substances being employed. The potatoes were grown in soil in tiles 23 in. in diameter, and the treatment consisted of sterilization and the use of formalin, potassium permanganate, sulphuric acid, sulphur, copper sulphate, carbon bisulphid, a commercial by-product called by the author "by-product A," etc.

Summarizing the results of the experiments, it is shown that many of the substances used had little effect in preventing scab, while others seemed to possess some value. Steaming the soil seemed to have but little effect on the production of scab. The best results were obtained by the use of by-product A in dry form, followed by sulphur treatment and by-product A in solution and steam heating. The by-product seems to act slowly and continuously as a germicide, and it is thought that it may prove efficient in the control of other fungi.

The relation of cane cultivation to the control of fungus diseases, J. R. JOHNSTON (*Porto Rico Sugar Producers' Sta. Circ. 3 (English Ed.), pp. 13*).—The author describes the various cultural methods that have been tested for growing cane, and points out methods to be adopted for the control of fungus diseases so far as any relation exists between them and the agricultural practices.

The black rots of the sweet potato, J. J. TAUBENHAUS (*Phytopathology, 3 (1913), No. 3, pp. 159-166, pls. 3*).—A study of the black rot of the sweet potato, described by Halsted (*E. S. R., 2, p. 416*) and since attributed to *Sphæronema fimbriatum*, has been made, and the author has come to the conclusion that the disease is not due to this species, but is a sclerotium fungus, to which the name *Sclerotium bataticola* n. sp. is given. In order to distinguish this disease from the black rot caused by *Trichoderma köningi*, it is proposed to call it the charcoal rot of the sweet potato.

A third black rot of the sweet potato is described, which is said to be due to *Lasiodiplodia tubericola*. For this the author proposes the name Java black rot, as this indicates the source from which the disease was first obtained.

Study of recent diseases of grapevines, their importance and treatment, V. C. M. DE ZÚÑIGA (*Estac. Enol. Haro Mem., 1912, pp. 85-98*).—Giving the results of several years' study of arrepollao or achaparrado (court-noué) of grapevines in the Rioja, Spain, the author states that this trouble although not very serious at present is more frequently met with on lowlands and levels and in valley bottoms than in higher portions of the valleys and on benches. Clayey, cold, compact soils appear to favor court-noué more than do loose stony or slaty soils, the percentage of moisture seeming to bear some relation to its appearance as do also abrupt temperature changes in winter and spring. Considerable differences are noted in the susceptibility of different varieties, Riparia and Berlandieri proving relatively resistant. It is thought also that vigorous growth in autumn tends to decrease the likelihood of this trouble in spring.

Downy mildew in Vaucluse in 1913, E. ZACHAREWICZ (*Rev. Vit., 40 (1913), No. 1025, pp. 171-174*).—Three outbreaks of downy mildew were noted in the Department of Vaucluse in 1913. Both copper sulphate mixed with powdered soap to the amount of 1.5 per cent each in water, and a mixture of 70 parts of sulphur with 30 parts of 20 per cent sulphosteatite, were used soon after rains with good results, as also was a treatment of powdered lime 55 parts, 20 per cent sulphosteatite 40 parts, and naphtha soap 5 parts, all these treatments be-

ing liberally applied. Employment of chemical fertilizers with some restriction as regards nitrogen is also claimed to prove helpful in producing a freer lineal growth of the shoots favorable to aeration and to the application of sprays. The chief reliance is placed upon copper sulphate as a basis of fungicidal treatment.

Mildew in 1913, A. CADORET (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 34 (1913), No. 34, pp. 238, 239).—In continuance of previous reports (E. S. R., 29, p. 551) the author states that, believing both single and successive outbreaks of downy mildew to be favored by humidity, he tested the effects of 3 sprayings following showers or rains extending over several days in the latter part of May and the early part of June. Almost no injury resulted from mildew, while crops around suffered heavily. Similar tests on a neighboring vineyard showed, however, a loss of about 50 per cent, heavy dews being noted in this case. Further tests are contemplated.

A Botrytis disease of dahlias, M. T. COOK and C. A. SCHWARZE (*Phytopathology*, 3 (1913), No. 3, pp. 171-174, pl. 1).—During the past year the authors' attention was called to a root rot of dahlias in storage. The disease appeared to be most severe under warm, moist conditions, combined with poor ventilation, and was caused by a species of *Botrytis* corresponding very closely to the description of *B. cinerea*. Infections always take place through wounds, and it was impossible to secure the penetration of the fungus through the uninjured epidermis.

Some fungus diseases of trees, L. H. PAMMEL (*Proc. Iowa Acad. Sci.*, 18 (1911), pp. 25-33, pls. 4, figs. 2).—Descriptions are given of the heart rot of *Populus tremuloides*, due to *Fomes ignarius* and *F. applanatus*; the oyster fungus (*Pleurotus ulmarius*) on box elder and basswood; the root rot fungus (*Polystictus versicolor*) on maples, oak, apple, cherry, and other deciduous trees; the root rot of oak, due to *Armillaria mellea*; the spot of butternut and black walnut (*Gnomonia leptostyla*); and attacks of *Taphrina* on the Rocky Mountain hard maples.

Shade tree troubles, G. E. STONE (*Massachusetts Sta. Rpt. 1912, pt. 1, pp. 73-83, pls. 7*).—The author describes staghead and root injury to maple and other trees, injury to cork cambium, sun scald, bleeding, injuries from snow, effect of grading on trees, and injuries from various treatments for protection against insect pests.

Chestnut blight, G. E. STONE (*Massachusetts Sta. Rpt. 1912, pt. 2, pp. 33, 34*).—A brief account is given of observations by the author on the spread of the chestnut blight and the injury which it is causing. This disease seems to be spreading in the Connecticut and other western valleys of the State, while the eastern central section of the State still remains comparatively free from the disease. Along with the blight there is said to be a deterioration of chestnut trees which is in no way associated with the blight fungus.

The blights of coniferous nursery stock, C. HARTLEY (*U. S. Dept. Agr. Bul. 44, pp. 21*).—The author describes the more common blights to which coniferous nursery stock is subject and offers suggestions for their control. Among those described are sun scorch, winterkilling, diseases due to parasitic fungi, stem girdle, mulch injury, red cedar blight, and mechanical root injury.

Sun scorch, which is said to be the commonest summer trouble, results in the death of the roots before the tops are killed and is due to excessive water loss. Watering, shading, and the avoidance of crowding, as well as increasing the humus content of the soil should be adopted for the prevention of this injury.

Winterkilling is due to the drying out of the plants when the soil is frozen and may be prevented by the use of a light straw mulch or windbreaks.

Mulch injury follows the heavy mulching of the plants and may be avoided by the use of light mulches and spraying with Bordeaux mixture before the application of the mulch.

The fungus diseases described are needle cast due to *Lophodermium pinastri*, blight caused by *Pestalotzia funerea*, root rots due to *Rhizoctonia* sp., and stem girdle caused by a fungus which may prove to be *P. hartigii*. Notes are also given on the red cedar blight, concerning which but little is known, and no recommendations are made for its control.

Herpotrichia and Neopeckia on conifers, W. C. STURGIS (*Phytopathology*, 3 (1913), No. 3, pp. 152-158, pls. 2).—The author reports having observed in northern Wyoming in 1902 the prevalence of a fungus on leaves and twigs of *Abies lasiocarpa* and *Picea engelmanni*. Later and in nearly the same locality what appeared to be the same fungus was found on *Pinus murrayana*. An examination made of the specimens collected showed that that occurring on the fir and spruce was *H. nigra*, while that on the pine was *N. coulteri*.

The damage caused by these two fungi is, so far as the author's observation goes, very slight, but on account of the possibility of their causing the destruction of conifers in seed beds or later, attention is called to them, and both species are described and their synonymy given.

A new rust, G. E. STONE (*Massachusetts Sta. Rpt. 1912, pt. 1, pp. 41-44*).—The occurrence in the State of the Cronartium form of *Peridermium strobi*, the cause of the white pine blister rust, is noted. The rust was observed on a block of 200 currant plants which had been introduced from a New York nursery. Nearly all the plants were infected, although a small block of black currants a quarter of a mile away showed no indication of the fungus, nor did a rigid examination of a plantation of 8-year-old pines reveal any signs of blister rust infection. As the black currants are not considered of any great economic importance the author suggests their destruction.

Spotting of rubber on the plantation, V. CAYLA (*Jour. Agr. Trop.*, 13 (1913), No. 145, pp. 221-223).—Referring to articles published by K. Bancroft (*E. S. R.*, 29, p. 451) and others, the author gives a brief outline of the beginning and progress of this condition of rubber appearing in the various stages of its production, mentioning several organisms found in connection therewith.

An investigation of lime-sulphur injury, its causes and prevention, V. I. SAFRO (*Oregon Sta. Research Bul.* 2, pp. 32, pls. 4).—Attention is called to the uncertain usage of the term lime-sulphur injury, and on account of this indefinite use the author has carried on some investigations to determine what chemical ingredients of the lime-sulphur spray can be classed as injurious in a strict sense.

A series of experiments was conducted in which the various materials which go to make up the spray and the compounds which are liable to occur in the spray before and after its application were used. These were sprayed on potato and bean foliage as well as on the foliage and fruit of apples, pears, cherries, peaches, and plums. Considerable varietal susceptibility to lime-sulphur injury was noted, but it was found that the injury, in the proper use of the term, was caused by the calcium polysulphids and to a somewhat less extent by calcium thiosulphate. The other normal ingredients occurring in the lime-sulphur mixture, either before or after its application, were found to be harmless.

A test was made of a number of samples of lime-sulphur mixture to determine whether their specific gravity could be taken as an index of their possible injurious effect. It was found that the specific gravity alone of the lime-sulphur spray does not indicate to what extent sulphids are in solution and

that different experiments using the densities of different concentrates as bases for dilution can not be compared accurately, so far as spray injury is concerned.

In an investigation made of means for the prevention of lime-sulphur injury it was found that it could be prevented to some extent by a considerable dilution of the solution or by the use of substances that would render the sulphids insoluble. Among those tested were iron, copper, and zinc sulphates, sulphuric acid, and carbon dioxide.

The author considers self-boiled lime sulphur to be a mixture of lime and sulphur rather than a combination. Much of the injury attributed to lime-sulphur sprays he attributes to other causes, particularly to sunburn.

Spreading capacity and adherence of sprays, V. VERMOREL and E. DANTONY (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 34 (1913), No. 25, pp. 778-780).—This is a brief general discussion of the constitution of sprays intended for ordinary protective purposes; also of those intended to be especially adapted to spreading on application or to adherence under adverse weather conditions, or to both these purposes.

Preparation of alkaline sprays, V. VERMOREL and E. DANTONY (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 34 (1913), No. 24, pp. 745, 746).—The authors give formulas and directions for the preparation of Bordeaux and Burgundy mixtures claimed to possess superior qualities as regards both spreading and adhesion, casein and gelatin being employed for this purpose.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Game protection and propagation in America, H. CHASE (*Philadelphia and London, 1913*, pp. V+238).—A handbook of practical information for officials and others interested in the cause of conservation of wild life.

Game law blue book, C. B. REYNOLDS (*New York, 1913*, pp. 136).—A compilation of the game and fish laws of the various States and of Canada, revised to date.

Rats and their extermination, W. A. DALEY (*Pub. Health [London]*, 27 (1913), No. 1, pp. 23-28).—This paper draws attention to the public health aspects of the rat problem and the methods of destroying these pests.

Rat proofing a municipal sewer system, F. SIMPSON (*Pub. Health Rpts. [U. S.]*, 28 (1913), No. 44, pp. 2283-2290).—A report of an investigation conducted with a view to finding a practical method of rat proofing the sewer system of San Francisco.

A history of the game birds, wild fowl, and shore birds of Massachusetts and adjacent States, E. H. FORBUSH (*Boston: Mass. Bd. Agr., 1912*, pp. XVI+622, pls. 37, figs. 108).—Following a brief introduction (pp. 1-35) the subject is dealt with under the headings of (1) a history of the birds now hunted for food or sport in Massachusetts and adjacent States (pp. 39-396); (2) a history of the game birds and other birds hunted for food or sport, which have been driven out of Massachusetts and adjacent States, or exterminated, since the settlement of the country (pp. 399-494); and (3) the conservation of game birds, wild fowl, and shore birds (pp. 497-595).

Insect porters of bacterial infections, C. J. MARTIN (*Brit. Med. Jour.*, 1913, Nos. 2714, pp. 1-8, figs. 12; 2715, pp. 59-68, figs. 12).—A summarized account delivered before the Royal College of Physicians.

Insect record for 1912 in Massachusetts, H. T. FERNALD (*Massachusetts Sta. Rpt. 1912*, pt. 2, pp. 85-87).—The year was made notable by the large number of different insects, some 400 forms, about which inquiries were made. Among the more important were various plant lice; the elm leaf beetle; the bronze birch borer (*Agrilus anxius*); the apple tree tent caterpillar; the apple

twig borer; the bud moth; the juniper scale (*Diaspis carueli*), a European pest which was found in such abundance on plants imported from abroad as to seriously injure them; the box leaf miner (*Monarthropalpus buxi*) which seriously attacked box hedges; the cottonwood leaf beetle (*Lina scripta*) which fed on the leaves of poplars in a nursery at Agawam; the chestnut borer (*Leptura zebra*), observed in connection with the chestnut bark disease; the fall army worm, which was unusually abundant and destructive; and termites (*Termes flavipes*) which attacked the stems of growing cabbages and corn plants.

General survey of the insect fauna of the soil within a limited area near Manchester; a consideration of the relationships between soil insects and the physical conditions of their habitat, A. E. CAMERON (*Jour. Econ. Biol.*, 8 (1913), No. 3, pp. 159-204, pls. 2, figs. 3).—Part 1 (pp. 159-187) of this paper consists of a general survey of the insect fauna of the soil at the grounds of the experimental laboratory, Fallowfield; part 2 (pp. 187-199) deals with the soil insects and the physical conditions of their habitat.

Phytopathological report for the year 1912, P. MARCHAL (*Bul. Agr. Algérie et Tunisie*, 19 (1913), No. 9, pp. 193-199).—This report deals with the occurrence of the more important insect pests of the year.

Report of the entomologist, E. BALLARD (*Nyasaland Dept. Agr. Ann. Rpt. 1913*, pp. 29-32).—This report deals largely with the occurrence of insect pests during the year.

List of insect pests, H. MORSTATT (*Pflanzer*, 9 (1913), No. 6, pp. 288-296).—This is a classified list of the more important insect enemies of plants and plant products in German East Africa, with the nature of their injury.

[Cranberry insects in 1912], H. J. FRANKLIN (*Massachusetts Sta. Rpt. 1912*, pt. 1, pp. 225-234).—This is a report of observations and study made of cranberry insects on Cape Cod in 1912 in continuation of those previously noted (E. S. R., 28, p. 352), and of which an account from another source has also been previously noted (E. S. R., 28, p. 854).

As regards the fruit worm (*Mineola vaccinii*) the author states that late holding of winter flowage is the surest method of control thus far discovered and that spraying as a remedy for it is still of doubtful practicability. There are, however, a few bogs which can not be winter flowed that will pay a moderate return if the fruit fly is kept within bounds. The experimental resanding of such a bog on May 23 to a depth of 1 in., the uprights being raked up through the sand when covered by it, was but partially successful, since numerous moths were observed on netting which covered the experimental plat and some 40 per cent of the berries which developed on this area were destroyed by fruit worms. The author thinks that the best treatment for this insect on such bogs would consist in the destruction of the remnant of the crop in the years when the severe injury either from frost or winter-kill occurs and that this could probably be most readily done by spraying with a 20 per cent solution of iron sulphate. It is his opinion that as a rule more is lost through injury done to the vine in harvesting a very light crop than is gained by saving and marketing the berries.

The flowed bog fireworm or blackhead cranberry worm (*Rhopobota vaccini-ana*) is the source of but little or no damage on bogs that are not winter flowed. The main cause of serious infestation by this pest is the killing and driving ashore of its natural enemies by flowage, as was pointed out in the report of the previous year. Through collections made by sweeping it was determined that spiders are the most numerous of all forms capable of destroying the fireworms. Comparisons showed that the dry bog had far more spiders and also a

somewhat larger number of parasitic insects than did any of the winter flowed bogs even as late as August 20. The information obtained in the study of this insect emphasizes the importance of spraying with arsenical poisons before the infestation starts. Since most bogs should be sprayed several times each year to control fungus diseases, Paris green for use against the fireworm may be applied at the same time by adding 1 lb. to every 50 gal. of Bordeaux mixture. A brief description is given of the most successful treatment for the control of the cranberry insects through the application of water to the bogs which has come to the author's attention. He states that there is little doubt that any bog can be freed from this fireworm by treating it for a few years as a strictly dry bog.

The season's observations of the cranberry girdler (*Crambus hortellus*) are said to sustain in every particular the conclusions concerning it reached the previous two years. Resanding every other year is usually sufficient to prevent infestation by it. Reflowing for a week or 10 days right after picking is still a standard remedy for it where sufficient water is available.

Methods of controlling mill and stored grain insects, together with the habits and life histories of the common infesting species, G. A. DEAN (*Kansas Sta. Bul.* 189, pp. 139-236, figs. 62).—The first part of this bulletin deals at some length with the use of heat as a means of controlling mill insects, and reports experiments conducted, many of the details of which have been previously noted from other sources (E. S. R., 29, p. 253). The author presents illustrations, temperature records, and other data relating to mills which have used heat successfully. Hydrocyanic acid gas treatment for mill insects is next taken up and described at length. This is followed by a discussion of carbon bisulphid fumigation as a means of destroying insects injurious to grain stored in granaries and small elevators. The last part of the bulletin (pp. 198-236) is devoted to a discussion of the habits and life history of the common stored grain and mill insects, some 25 of which are described and figured.

"The only practical and efficient method at present known of completely controlling all classes of mill-infesting insects is by the application of high temperatures, and this method has been so developed within the last 3 years that it promises to revolutionize the present inadequate methods. In Kansas the heating of several mills has absolutely proved that no stage of a mill insect, even in the most inaccessible places, could withstand the heat, and several mills in Ohio, Illinois, Nebraska, Iowa, Indiana, southern Canada, and elsewhere have corroborated the practicability and the efficiency of heat as a means of controlling mill insects. . . . Many insects do not yield readily to hydrocyanic acid gas, but no mill insect can withstand for any length of time a temperature of from 118 to 122° F. . . .

"A mill that has sufficient radiation to heat it in winter to a temperature of 70° can readily be heated in summer to a temperature of from 118 to 122°. With the heat method there is no possibility of injuring the floors, belts, or mill machinery and there is practically no danger from fire. The Mutual Fire Prevention Bureau, representing eight of the principal millers' insurance companies, recommends the heating system for effective fumigation against all mill and stored grain infesting insects. If a mill is infested with Mediterranean flour moth, hydrocyanic acid gas is a very effective treatment, but in no case where it is possible to use heat is the hydrocyanic acid gas treatment recommended."

The destruction of injurious insects by vegetable parasites, L. LE MOULT (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 34 (1913), Nos. 34, pp. 239-246; 35, pp. 265-277; 36, pp. 297-308).—This is a general review.

Tests of insecticides, H. T. FERNALD (*Massachusetts Sta. Rpt. 1912, pt. 2, pp. 88-91*).—Several insecticides were tested during the year but no attempt was made to draw final conclusions as to their value.

Entomoid, claimed to be a combination of lime-sulphur and a miscible oil, applied at the strength of 1:50 killed many San José scales, but a sufficient number were left so that the trees were about in their former condition at least 3 months earlier than was the case in 1911. Nicine, used in large amounts in drills to protect corn from wireworms and about the base of onions to protect them from the onion maggot, had no injurious effect on the plants but did not give absolute protection from a light infestation of wireworms nor afford a high degree of protection from the maggot. Soil Fumigant and Insecticide was applied to parts of the same corn plats as Nicine to protect corn from wireworms but the infestation proved to be insufficient to enable a determination of its value. Tests with two commercial brands of zinc arsenite applied at the rate of 1 lb. to 10 gal. of water to elm, maple, and wild cherry leaves showed that both adhered well and destroyed the elm leaf beetle larvæ, but injured the leaves of all three trees. Both applications are believed to have been too strong.

The common house roach as a carrier of disease, R. C. LONGFELLOW (*Amer. Jour. Pub. Health, 3 (1913), No. 1, pp. 58-61*).—Attention is called to the rôle of this insect in the dissemination of various species of bacteria.

Notes on the occurrence of the woolly aphis, *Schizoneura lanigera*, in the core of apples, T. R. HEWITT (*Jour. Econ. Biol., 8 (1913), No. 2, pp. 95-98, fig. 1*).—The author has found the core of Newtown Pippins from California that were purchased from a Dublin fruit dealer to be infested with *S. lanigera*. In 3 of 7 apples examined the aphids were alive. It is stated that externally the apples did not appear to be infested, except for a little mildewy appearance of the eye, but on being cut in two through the core the aphids were easily seen. There is a small channel connecting the eye with the core in this apple and through this channel the aphids gained access to the core. This channel, however, is not common in many varieties.

"The core presented a white moldy appearance, due to the woolly secretion of the aphids. In the apples in which the aphids were dead the cores were moldy, due to the growth of some fungus, which was probably secondary. The damage done to the core was very slight, as the aphids did not appear to have pierced through the carpels. In one apple, which was rather more badly infested than the others, the seeds presented a damaged appearance, but the flesh of the apple was not injured in any instance."

The economic importance of such infestations is found in the possible dissemination of this pest in apples to uninfested orchards or districts.

Report on peach aphis investigations during late winter and early spring, 1912, C. B. HARDENBERG (*Agr. Jour. Union So. Africa, 6 (1913), No. 2, pp. 224-235*).—This is a report of studies of the life history and of control experiments with the black and green peach aphids in the Transvaal.

The black peach aphis is said to be attacked by a hymenopterous parasite and 2 syrphids, *Xanthogramma scutellaris* and an undetermined species. The green peach aphis suffers in addition from the attack of a third species of syrphus fly, and 3 species of lady beetles have been found to feed upon it. Observations of the life cycle of *X. scutellaris* are reported.

Tobacco extract in a solution containing about 0.082 per cent nicotin is the most effective strength and no advantage is gained in using a stronger solution. The green peach aphis can be effectively kept under control by 3 thorough sprayings about 5 days apart, the first being applied as soon as the first leaves open out.

The San José scale in Tennessee with methods for its control, G. M. BENTLEY (*Tenn. Bd. Ent. Bul. 8, 1913, pp. 24, figs. 21*).—This account has been previously noted from another source (*E. S. R., 29, p. 53*).

Some preliminary notes on a scale insect infesting the banana in Fiji, F. P. JEPSON (*Dept. Agr. Fiji Bul. 5, 1913, pp. 7; abs. in Rev. Appl. Ent., 1 (1913), Ser. A, No. 4, p. 136*).—This paper relates to the infestation of bananas by the transparent coconut scale (*Aspidiotus destructor*).

The Abutilon moth (*Cosmophila erosa*), F. H. CHITTENDEN (*U. S. Dept. Agr., Bur. Ent. Bul. 126, pp. 10, pls. 5*).—This is a summarized account of the present knowledge of the Abutilon moth, the larvæ of which defoliate okra, hollyhock, and Abutilon in Virginia and the District of Columbia. It has also been observed feeding on *Hibiscus esculentus* and *Malva rotundifolia* in the District of Columbia and on cowpeas in Mississippi. Technical descriptions are given of its several stages.

The application of a spray consisting of 40 per cent nicotin sulphate $\frac{1}{2}$ oz., whale-oil soap $\frac{1}{2}$ lb., and lukewarm water 5 gal. resulted in the destruction of 95 per cent of the larvæ. A second application resulted in the complete eradication of the pest.

A bibliography of 10 titles is appended.

The red-humped caterpillar (*Schizura concinna*), E. J. VOSLER (*Mo. Bul. Com. Hort. Cal., 2 (1913), No. 9, pp. 654-657, figs. 2*).—Considerable damage to the apple, walnut, etc., is often caused in the central portion of California by this pest.

The fruit tree leaf roller (*Archips argyrospila*), G. P. WELDON (*Mo. Bul. Com. Hort. Cal., 2 (1913), No. 9, pp. 637-647, figs. 6*).—This leaf roller is said to have ruined much of the fruit in several orchards in San Diego County, Cal.

A new sugar-cane pest, C. FULLER (*Agr. Jour. Union So. Africa, 5 (1913), No. 6, pp. 931-933*).—This paper deals with a caterpillar which webs together the immature leaves forming the spike of the cane and, living within the protecting tube so formed, feeds upon the inner surface of the outer leaf forming the spike.

The Hessian fly, T. J. HEADLEE and J. B. PARKER (*Kansas Sta. Bul. 188, pp. 83-138, figs. 15*).—In this bulletin the authors have brought together the results of their personal investigations in Kansas, together with a review of the more important findings of other investigators. The subject is dealt with under the headings history and distribution, habits and life history, seasonal history, natural checks, injury, and measures of control. A diagram depicting the life history is included (see fig. 1).

It is stated that six different outbreaks of the Hessian fly have occurred in Kansas during the 41 years that it is known to have been present there. During the last and greatest of these outbreaks, that of 1908, 10,000,000 bushels of wheat were destroyed.

The length of its life cycle is variable, ranging under field conditions from 45 days to 12 months or more, dry weather and cool weather lengthening it, and moist and warm weather shortening the period. "The number of broods is variable. In 1908 main-spring, supplementary-spring, midsummer, main-fall, and supplementary-fall broods were determined. In dry summers it is likely that midsummer and supplementary-fall broods would not appear, and it is likely that in very dry years, particularly when the drought begins early, the supplementary-spring brood might be eliminated."

Under measures of control mention is made of grazing, rolling or brushing, mowing, fly-proof wheat, spraying and dusting infested plants, intermittent wheat culture, and trap planting as of little, if any, value. The useful methods include the destruction of the fly in infested stubble by burning or plowing

under, the destruction of volunteer wheat, and late sowing. "The sources of the flies which form each of the broods are variable, for the members of a single brood came from as many as three different places—old stubble, regular crop, and volunteer wheat. The measures of control must be of such a nature as to close up all these sources of supply. Temperature and moisture are the only climatic elements that appear materially to influence the fly. Low temperature or low moisture, or both acting simultaneously, always retard its development,

FIG. 1.—Diagram to represent the number of broods of Hessian fly in Kansas in 1908, the period of their appearance, and the sources from which they came.

and may, if extreme, destroy it. High temperature and high moisture are universally favorable to its development. Although both predaceous and parasitic enemies always reduce the fly, their action is so irregular and so rarely sufficient that dependence upon them for protection is folly . . . In the fall the central shoot of the young plant is stunted and killed; if the attack be serious enough, the whole plant and the whole field may be destroyed. Ordinarily the slow destruction of the central shoots causes the tillers to grow vigorously, giving the

field a dark green appearance. In the spring, the maggots interfere with the sap flow, cause the heads partly or completely to fail to fill, and so weaken the stalks that many break and fall before harvest. The fly infesting the old stubble can best be destroyed by plowing the stubble under so carefully and deeply that when the ground is packed down into a good seed bed for wheat, there will be at least 4 in. of soil between the stubble and the surface. The growth of volunteer wheat is a menace, and should not be tolerated before the regular crop is sown. In average years with proper preparation of the seed bed, the date of safe sowing is at least as early as the date on which wheat should be sown to make a maximum yield if no fly were present."

A schedule of procedure based upon the life history studies here reported is outlined which if it is followed it is thought will enable the farmer to escape serious fly damage and give the best possible chance to obtain a maximum crop. A map of Kansas which shows the date of safe sowing calculated directly from 1907-8, 1908-9, and 1909-10 experimental sowings is included, from which the safe-sowing date may be readily determined for the various counties.

The red clover gall gnat (*Amblyspatha ormerodi* n. sp.), R. S. MACDOUGALL (*Jour. Bd. Agr. [London]*, 20 (1913), No. 3, pp. 225-230, pls. 4).—A great destruction of red clover by this cecidomyiid is reported to have taken place during the winter and spring of 1912-13, complaints having been received from a large number of counties. In practically all the samples received red maggots were found either in the soil surrounding the plants or, on dissection, in the spoiled plants.

It is thought that a fungus of the genus *Sclerotinia* and an eelworm (*Tylenchus devastatrix*) may be associated with the gall midge in the injury.

A jumping maggot which lives in cactus blooms (*Acucula saltans* n. g. and n. sp.), C. H. T. TOWNSEND (*Canad. Ent.*, 45 (1913), No. 8, pp. 262-265).—A new dipteran collected from a columnar cactus, probably *Cereus* sp., at the western base of the Andes some 40 miles inland from Lima, Peru, is described as *A. saltans*. This maggot causes the petals to shrivel before they open.

Mosquito extermination and its problems, E. WINSHIP (*Engin. Rec.*, 67 (1913), No. 18, pp. 490-492, figs. 2).—A discussion of the subject by a sanitary engineer in which he outlines the essentials of success in ridding communities of the pest.

The natural host of *Phlebotomus minutus*, F. M. HOWLETT (*Indian Jour. Med. Research*, 1 (1913), No. 1, pp. 34-38, pl. 1, fig. 1).—The author finds the wall lizard, or gecko, to be the natural host of *P. minutus*. He states that there is no doubt but that this fly has a distinct preference for biting lizards as compared with man, and that it is in fact primarily a parasite of the lizard. A *Phlebotomus* (probably *P. minutus niger*) has once been observed biting an agamid lizard, and a sand fly has been observed twice biting the head of the common toad (*Bufo melanosticticus*).

Recent literature, especially the medical literature, on sand flies (*Phlebotomus*, *Simulium*, *Ceratopogoninae*), K. FRIEDERICHs (*Ztschr. Wiss. Insektenbiol.*, 9 (1913), Nos. 1, pp. 26-31; 4, pp. 133-138).—This review follows a list of 63 recent publications on the subject.

Control measures for use against flies, L. VAILLARD (*Rev. Sci. [Paris]*, 51 (1913), II, No. 7, pp. 193-206, figs. 7; *Rev. Gén. Sci.*, 24 (1913), No. 9, pp. 352-358; *Off. Internat. Hyg. Pub. [Paris]*, *Bul. Mens.*, 5 (1913), No. 8, pp. 1313-1336).—A detailed discussion.

The distance house flies, blue bottles, and stable flies may travel over water, C. F. HODGE (*Science, n. ser.*, 38 (1913), No. 980, pp. 512, 513).—This paper describes a plague of flies on the cribs of the waterworks, situated 14, 5, and 6 miles, respectively, out in Lake Erie, from the city of Cleveland, Ohio.

"The only explanation for the above facts seems to be that the flies are blown at least 6 miles off shore, and that they gather on the cribs as temporary resting places."

An unusual outbreak of *Stomoxys calcitrans* following floods, C. FULLER (*Agr. Jour. Union So. Africa*, 5 (1913), No. 6, pp. 922-925).—A discussion of an unusual outbreak of the stable fly in South Africa.

The maggot fly pest in sheep, H. S. MAJOR (*Agr. Gaz. N. S. Wales*, 24 (1913), No. 8, pp. 645-653).—A discussion of this pest has been previously noted from another source (*E. S. R.*, 29, p. 656).

The bean stem maggot, R. W. JACK (*Rhodesia Agr. Jour.*, 10 (1913), No. 4, pp. 545-553, pls. 4).—The author here discusses the life history, bionomics, and injury caused by *Agromyza fabalis*, a native African species which is generally distributed south of the Zambesi. This dipteran is said to be the most serious drawback to the successful cultivation of cowpeas and certain other kinds of beans in this territory.

Experiments for the control of the onion maggot, H. T. FERNALD and A. I. BOURNE (*Massachusetts Sta. Rpt. 1912, pt. 1, pp. 171-179*).—This paper presents the details of experiments in which a number of insecticides and repellents were tested with a view to determining their efficacy in controlling the onion maggot.

The experiments with carbon bisulphid, Nicine, powdered hellebore, a hellebore decoction, a soap wash, carbolized lime, and kerosene emulsion gave what may be considered as negative results. More satisfactory results were obtained in the control of the maggots from the application of carbolic acid emulsion, made by dissolving 1 lb. of soap in 1 gal. of water, adding 1 lb. of crude carbolic acid, and churning as in kerosene emulsion. Applications along the rows by means of a force pump without a nozzle at strengths of 1:30, 1:40, and 1:50 parts of water decidedly checked the infestation in the rows to which it was applied. It is estimated that the cost of this material and labor varies from \$8 to \$12 per acre for each application, according to the strength used. Since it would be necessary to make at least 3 and probably 4 applications, the cost would amount to from \$35 to \$50 per acre.

"The whole experiment indicates (a) that no entirely effective method of controlling the onion maggot has as yet been discovered; (b) that many of those thus far recommended are of little value, at least on large fields; (c) that the cost of treatment with most of them is so great as to render them unavailable for large areas. Finally, the most promising line of investigation seems to be the discovery of something which will effectually repel the insects or destroy the maggots, and which can be applied either as a part of the planting process or in connection with cultivation, thus avoiding the necessity of special treatments by combining these with usual methods of cultivation."

The manzanita Serica (*Serica anthracina*), E. O. ESSIG (*Mo. Bul. Com. Hort. Cal.*, 2 (1913), No. 8, pp. 622, 623, fig. 1).—This beetle is reported to be a source of serious injury in Eldorado County, California, through its defoliation, especially of the prune and apple. In some instances the trees have been killed by the constant and complete defoliation.

The application of arsenate of lead, at the rate of 8 lbs. to 100 gal. of water to which 8 lbs. of lime has been added, as soon as the beetles appear in the spring is recommended.

A critical discussion of the Halticini attacking Cruciferae in central Europe, F. HEIKERTINGER (*Centbl. Bakt. [etc.]*, 2. Abt., 36 (1912), No. 1-5, pp. 98-127, figs. 18).—The several parts of this paper deal with the genera and species of flea beetles attacking crucifers and the nature of their injury, the cultivated crucifers attacked, tables for the determination of the species of

Phyllotreta and *Psylliodes* infesting Cruciferae in Germany, Austria, and Switzerland, etc.

The destructive *Eleodes* (*Eleodes omisssa borealis*), E. O. ESSIG (*Mo. Bul. Com. Hort. Cal.*, 2 (1913), No. 8, p. 627, fig. 1).—This tenebrionid beetle is reported to have been the source of injury to orange trees around Bakersfield and to have stripped a large number of apricot and plum trees in an orchard at Wasco, Kern County.

The fruit tree bark beetle (*Scolytus rugulosus*), E. O. ESSIG (*Mo. Bul. Com. Hort. Cal.*, 2 (1913), No. 9, p. 658).—The author records the occurrence of the shot-hole borer in apricot trees at Ontario, Cal., this being the first authentic report of its occurrence in the State.

Investigations of the fungus-growing fruit tree bark beetle *Xyleborus* (*Anisandrus*) *dispar* and its food fungus, O. SCHNEIDER-ORELLI (*Centbl. Bakt. [etc.]*, 2. Abt., 38 (1913), No. 1-6, pp. 25-110, pls. 3, figs. 7; *abs. in Rev. Appl. Ent.*, 1 (1913), Ser. A, No. 8, pp. 259-261).—This is a report of a detailed study of the bionomics of the scolytid beetle *X. dispar* and contains the results of numerous experiments regarding its feeding habits. The experimental propagation of its food fungus *Monilia candida* is also discussed.

The females emerge from their burrows in the spring and soon commence a new system of burrows, the walls of which become lined with a dense mass of this so-called ambrosia fungus upon which the larvæ feed. The spores are said to be spread through being taken up by the adult beetles, and later regurgitated from the stomach.

A billbug injurious to small grain (*Sphenophorus discolor*), H. S. SMITH (*Mo. Bul. Com. Hort. Cal.*, 2 (1913), No. 8, pp. 619-621, figs. 3).—Considerable injury is said to have been caused by *S. discolor* to all varieties of barley, wheat, and oats in the vicinity of Sacramento.

Black brood in bees, I. L. SERBINOW (*Vestnik Russ. Obshch. Pchelovod.*, 1912, No. 11, pp. 426-429; *abs. in Rev. Appl. Ent.*, 1 (1913), Ser. A, No. 3, pp. 94-96).—This article relates to European foul brood and its occurrence in Russia.

A preliminary account of a chalcidid of the genus *Tetrastichus* which parasitizes *Ceratitis* and *Dacus* in West Africa, F. SILVESTRI (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 22 (1913), II, No. 5, pp. 205, 206).—A new species of *Tetrastichus* reared from *Ceratitis stictica*, *C. giffardii*, and *Dacus cucumarius* in Nigeria, Kamerun, Gold Coast, and Dahomey is described under the name *T. giffardii*.

A new braconid of the genus *Microdus* from Canada, C. H. RICHARDSON, JR., (*Canad. Ent.*, 45 (1913), No. 7, pp. 211, 212).—A new braconid reared from the eye-spotted bud moth at Bridgetown, Nova Scotia, is described as *Microdus ocellanae*.

The enemies of plant pests: The Aphelininae, R. G. MERCET (*Trab. Mus. Cien. Nat. [Spain]*, 1912, No. 10, pp. 306, figs. 68).—A synopsis of this important group of chalcidid parasites, including tables for the separation of genera and species, is presented.

Collembola damaging pine trees, W. E. COLLINGE (*Jour. Econ. Biol.*, 8 (1913), No. 2, p. 99).—The author reports finding that *Seira nigromaculata* causes the young needles on shoots of *Pinus sylvestris* to wither and drop. "The insect seems to be attracted by the resinous gum, and as soon as the leaf bud opens makes its way to the bases of the young leaves and commences to bite into the same; after a short time the needles turn yellow and ultimately fall away. Sometimes only part of the base is destroyed and part of the bud remains in a damaged condition, but in most cases the new buds are completely ruined."

Experiments in the use of sheep in the eradication of the **Rocky Mountain spotted fever tick**, H. P. Wood (*U. S. Dept. Agr. Bul. 45, pp. 11*).—This is a report of experiments conducted to determine the value of sheep in destroying *Dermacentor venustus* as brought to attention by L. D. Fricks in an article previously noted (*E. S. R.*, 29, p. 658).

Two experiments, the first with 20 sheep, the other with 2 sheep, were carried through. The first was conducted in a country known to be well infested with ticks, being adjacent to the foothills and well supplied with bushes of various sorts, a growth of small pines, a few fairly large trees, and several streams of water. The conditions were such that there could have been few, if any, ticks on the sheep at the time they were driven into "ticky" country. During the course of the experiment, which was commenced on June 3, two thorough examinations were made, commencing June 10 and 23, respectively, of each sheep to locate the living ticks and to remove the dead ones. Numerous other, but less thorough, examinations were also made, when any dead found were removed and the living ones noted. In the second experiment ticks were collected by dragging cloths over the ground, and then placed upon the sheep—on the first June 20 and on the other June 25, the examinations also being made twice a day. The details of the results are presented in both tabular and descriptive form.

The experiments show that sheep are good collectors of ticks, 6 sheep with heavy wool having picked up 72 females and 47 males in 11 days. Thus in "ticky" country which is favorable to the herding of sheep it would be advantageous to use them as collectors of ticks, since by dipping the sheep once in 7 days it would seem that much good could be accomplished. In order to bring about the greatest good it would be necessary to herd the sheep with a knowledge of the location of the ticks, since it is extremely doubtful if they would be of much importance as collectors of ticks if allowed to run free. Of 33 female ticks placed upon a sheep in the second experiment but one fed sufficiently to lay eggs. There were in all, however, 6 females which stood a fair chance of engorging, so that it is difficult to say what percentage of females that get on a sheep in nature will engorge to repletion.

Several limitations to the practicability of using sheep exclusively in the eradication of the spotted fever tick, namely, (1) the necessity of eliminating all other live stock except that on which the ticks could be destroyed at weekly intervals by dipping or otherwise; (2) the impracticability of heavily stocking a given area with sheep and attempting to carry the usual number of other live stock on the same pastures; and (3) the necessity of cutting down all vegetation higher than a sheep's back, emphasize the great importance of following the plan of dipping domestic animals which is successfully under way. Thus while sheep may be used under some conditions of the work, the main reliance must be upon the dipping of horses and cattle.

FOODS—HUMAN NUTRITION.

Bouillon cubes—their contents and food value compared with meat extracts and homemade preparations of meat, F. C. Cook (*U. S. Dept. Agr. Bul. 27, pp. 7, figs. 10*).—The composition and nature of commercial bouillon cubes are discussed on the basis of analytical data, in comparison with commercial meat extracts and similar preparations and homemade broths and soups.

The author's summary follows.

"One-half to three-fourths of bouillon cubes is table salt. The cubes are not concentrated beef or meat essence, as many people believe. They are valuable stimulants or flavoring agents, but have little or no real food value. Bouillon cubes, therefore, are relatively expensive.

"Semisolid meat extracts sold in jars are not concentrated beef. They are stimulants and flavoring adjuncts and have only a slight food value, owing to a small amount of protein (muscle-building food) which they contain. They are more expensive than homemade soups.

"Fluid meat extracts are dilute solutions of semisolid meat extracts. They are sold in bottles and are flavored. They are more expensive than the semisolid meat extracts because they contain more water.

"Commercial meat juices are largely deprived of their most valuable food constituent—the coagulable protein, or muscle-building food. They are similar to fluid meat extracts, and some makes cost more.

"Homemade meat broth is more nutritious and provides more meat extractives, protein, and fat at less expense than the commercial preparations.

"Homemade meat and vegetable soup contains much more food and is therefore much cheaper than the bouillons or soups prepared from commercial cubes, extracts, or juices."

Bouillon cubes, F. C. COOK (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 12, pp. 989, 990).—Analytical data are reported regarding the bouillon cubes referred to above.

"Bouillon cubes on the market at present consist of about 5 per cent of water, 1 to 4.5 per cent of ether extract (fat), and 50 to 74 per cent of ash which is practically all sodium chlorid. The nitrogen bodies and undetermined organic material amount to 20 to 40 per cent. The phosphoric acid (P_2O_5) varies from 0.4 to 1.8 per cent, the total nitrogen from 2.1 to 3.6 per cent, and the total creatinin from 0.49 to 1.67 per cent.

"A cube prepared largely from meat extract gives high total phosphoric acid (P_2O_5), total nitrogen, and total creatinin figures. The amount of nitrogen precipitated by absolute alcohol and hydrochloric acid is also markedly higher than in a cube containing much plant and little meat extract. . . .

"Bouillon is a clear broth, the basis of which is meat; consequently a true bouillon cube should show high creatinin and high total nitrogen figures, and should be prepared entirely, or largely from meat stock or meat extract in addition to the salt and fat present. Several of the cubes on the market contain much more plant than meat extract and are not entitled to the name 'bouillon' unless modified."

Notes on rare fishes sold for food in east London, F. J. STUBBS (*Zoologist*, 4. ser., 17 (1913), No. 202, pp. 377-381).—These notes were collected during the preparation for the Whitechapel (Stepney Borough) Museum of an exhibit of the food fishes for sale in east London and include, besides a description of the method of making casts of the fishes, brief notes on the habitat and appearance of the less common varieties. Among the latter are the greater weever (*Trachinus draco*), beryx (*Beryx decadactylus*), sea bream (*Pagellus centrodontus*), ide (*Leuciscus idus*), sile smelt (*Argentina silus*), lesser ling (*Molva dipterygia*), *Macrurus rupestris*, *Malacocephalus laevis* (*Macrurus laevis*), and lumpsucker (*Cyclopterus lumpus*).

Size of the sample necessary for the accurate determination of the sanitary quality of shell oysters, G. H. SMITH (*Amer. Jour. Pub. Health*, 3 (1913), No. 7, pp. 705-708).—According to the author, consistent results can not be obtained with less than 15 oysters. A standard of purity for oyster liquor should be established similar to the standards in use for water and milk.

Studies of phosphatids, particularly those in egg yolk, J. EPPLER (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 87 (1913), No. 4, pp. 233-254).—Analytical data are reported and discussed.

The gluten content of flour, K. BUDAI (BAUER) (*Ztschr. Gesam. Getreidew.*, 5 (1913), No. 6, pp. 171-179).—General and analytical data are given regarding the amount of gluten in different flours and its relation to their quality.

A preliminary study on the conditions which affect the activity of the amylolytic enzymes in wheat flour, C. O. SWANSON and J. W. CALVIN (*Jour. Amer. Chem. Soc.*, 35 (1913), No. 10, pp. 1635-1643).—The effects of temperature, the duration of the digestion period, the optimum proportion of flour and water, and the effect on the production of reducing sugars of chemicals were studied, including sulphuric acid, sodium hydroxid, dibasic potassium phosphate, and sodium chlorid in varying concentrations and quantities.

The experiments, according to the authors, showed that "the optimum temperature for the production of the maximum amount of reducing sugars is very near 65°; that the best proportion of water and flour lies between 1:4 and 1:10, and that there is little difference between these two limits. It has also been shown that the largest transformation takes place during the first hour; approximately 88 per cent of the total change occurs during the first hour. The inhibiting effect of various chemicals has been shown. The inhibiting action is greater toward straight flour than toward low-grade."

Some points in the making and judging of bread, ISABEL BEVIER (*Univ. Ill. Bul.*, 10 (1913), No. 25, pp. 44, pls. 7).—As the author points out, the characteristics of good bread are symmetry of size and shape, bloom and crispness of crust, and a tender, elastic crumb of fine grain. The conclusions drawn from the investigation were in effect the following:

Recipes differ widely as regards nonessentials, sugar, salt, and shortening, but agree as to the proportion of 1 cup of liquid to 3 of flour. Yeast is a plant, and so subject to laws of plant growth as regards food and moisture. If in good condition, yeast probably does not influence the flavor of bread. Water is the best liquid as regards flavor. Because of the small proportion used and the fact that almost any form of milk is largely water, little effect on flavor is produced by the use of skim milk or buttermilk. Both seem to contribute to tenderness of crumb.

Salt prevents a flat taste, retards fermentation, and, used to excess, causes loss of color in crust and of tenderness in crumb. Sugar darkens the color of the crust. Within limits, it increases the volume of the loaf. Salt and sugar combined in proportion of 1:2, respectively, improve both flavor and volume.

Bread making is an art that demands careful attention to certain essential details such as character, temperature, and amount of yeast, condition and amount of flour, time and temperature of fermentation and baking. The material of pans is a question of choice. Tin seems to yield the best results in common practice. Covered and uncovered pans have not been tried enough for definite conclusions.

The process of bread making for winter wheat flour differs from the process for spring wheat flour in that winter wheat requires more liquid, a slacker dough, is much better with 3 risings instead of 2, and should be allowed to finish proving in the oven.

A new method of keeping bread fresh and its significance with respect to the night work of bakers, J. R. KATZ (*Chem. Weekbl.*, 10 (1913), No. 24, pp. 488-495, figs. 3).—Experiments on the vapor tension and water content of bread crust showed that so long as the moisture did not exceed 18 per cent the crust retained the characteristics of freshness. In an atmosphere with 85 per cent humidity bread crust remained unaltered for a long time.

Bread remained fresh from 10 to 15 hours when kept in a chamber which contained a shallow pan filled with saturated salt solution, and in which an air circulation was maintained by means of a small ventilating fan. The only

regulation necessary was the addition of water to the brine to maintain the desired concentration. In the author's opinion, such apparatus is particularly well suited to small bakeries, and by its use he believes that it might be possible to do away with night work.

The grinding of corn meal for bread, F. P. DUNNINGTON (*Alumni Bul. Univ. Va.*, 3. ser., 6 (1913), No. 4, pp. 521-532).—The data discussed in this paper were reported in an earlier publication (*E. S. R.*, 28, p. 360).

[Banana recipes], O. W. BARRETT (*Philippine Agr. Rev. [English Ed.]*, 6 (1913), No. 9, pp. 451, 452).—In a discussion of the use of bananas recipes are given for preparing bananas and plantains for the table.

Hickory nuts and hickory nut oil, G. O. PETERSON and E. H. S. BAILEY (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 9, pp. 739, 740).—An analysis of hickory nut meats is reported in connection with a study of the oil and its characteristics.

According to the authors, "the food value of hickory nuts is high; the oils from the two species of hickory nuts, *Carya ovata* and *C. amara*, are practically identical and are similar to cotton-seed oil; the oil retains the flavor of the hickory nut, and is practically equal to olive oil; [and] the possibility of extracting the oil on a commercial basis should be further investigated."

[Analyses of food, beverages, and drugs], W. HANSON (*Bien. Rpts. State Dairy and Food Comr., State Chem. and State Dairy and Food Bur. Utah, 1911-12*, pp. 191).—The results of a large number of analyses of foods, beverages, and drugs are reported and discussed, and reports of the 2 years' work are presented.

Food and drug and weight and measures laws of the State of Nevada, with the rules and regulations adopted for the enforcement of the same (*Nevada Sta. Bul.* 80, pp. 22).—The full text of the state laws, rules, and regulations is given.

Wisconsin dairy and food laws and decisions of courts, J. Q. EMERY (*Madison, Wis.; Dairy and Food Comr., 1913*, pp. 92).—A compilation of the state laws regarding the inspection, manufacture, and sale of food and dairy products, as amended in 1913, together with court interpretations and rulings.

A study of the use of ice and other means of preserving food in homes, J. R. WILLIAMS (*Jour. Amer. Med. Assoc.*, 61 (1913), No. 12, pp. 932-935, figs. 2).—In this paper, read in the section on preventive medicine and public health of the American Medical Association, Minneapolis, June, 1913, the results are presented of a study of upwards of 100 homes in 5 sections of Rochester, N. Y., socially and economically different. Information was collected regarding the use of milk, means for caring for it, the size, make, and kind of refrigerator used, the amount of ice used weekly and yearly with its cost, and similar topics, and temperature measurements were made of refrigerators, living rooms, and cellars. From his studies the author considers that the following conclusions are warranted:

"The temperatures of cellars or living rooms in dwelling houses are not sufficiently low during the warm months of the year to protect milk and other perishable foods from rapid bacterial decomposition. Therefore an efficient refrigerator in the home is a necessity.

"Most of the refrigerators in common use are almost worthless and grossly uneconomical. There is a large field for the manufacturer who will make a properly insulated and efficient box which can be sold at a moderate price.

"If more economical methods of ice manufacture and distribution were employed, the cost of ice to the consumer could be materially lowered. If to this saving were added that which would result from proper ice box construction,

refrigeration vastly superior to that now found in the average home could be had for at least one-fourth the present cost."

The paper is followed by a discussion.

Cooking and heating with electricity, C. T. PHILLIPS (*Architect and Engin.*, 34 (1913), No. 3, pp. 93-99, figs. 7).—Electric cooking equipment of different sorts is described and data summarized regarding the rates for electricity for cooking purposes in different parts of the United States and the cost of cooking by this method.

The food factor in some sociologic problems (*Jour. Amer. Med. Assoc.*, 61 (1913), No. 16, p. 1463).—In discussing the problem of food in relation to sociological problems, the following statement is made:

"Perhaps our sociologists have not sufficiently appreciated in the past that the occurrence of conditions in which the support of the family and the provision of even the barest necessities prevent the attainment of any variety and interest in life and almost enforce a monotonous existence reacts in a variety of ways on the health and efficiency of the community through the diet factors referred to. The essays at amelioration and reform must accordingly take into account possible changes in the mode of feeding which might set free a greater proportion of the income for other things than food. Dietary habits need to be dealt with in this field quite as much as ignorance and the 'stultifying influence of the surroundings.'"

[Increased cost of maintenance of children] (In *Special Report Chicago Nursery and Half-Orphan Asylum, 1860-1913*. Chicago [1913], pp. 12, 13).—Since its establishment in 1874 the institution has cared for more than 4,500 children for periods varying from a few weeks to a long term of years.

A gradual increase in the cost of support per child has been noted. The average cost of maintenance from 1874 to 1883 was \$79.98 per child per year; from 1884 to 1893, \$88.68; from 1894-1903, \$101.45; and from 1904 to 1913, \$140.60. These estimates "do not take into account the numerous contributions of food, clothing, and general equipment which have made it possible to keep the expenses down to these figures. Nor do they include the maintenance, repairs, and improvements of the building."

Cost of living in Nova Scotia, J. W. RAGSDALE (*Daily Cons. and Trade Rpts.* [U. S.], 16 (1913), No. 157, p. 134).—Data are given regarding the kinds and amounts of food consumed by a family consisting of a man and woman and 4 children.

[Using the usual factors for the composition of food, etc., it has been calculated that the food purchased for this family (calculated to be equal to 3.7 men) supplied 116 gm. protein and 3,325 calories of energy per man per day.]

Food prices in London—an inquiry into present conditions as affecting the poorer classes of workers, J. C. PRINGLE (*London: Charity Organ. Soc.*, 1913, pp. 36).—A large amount of statistical data is summarized and discussed with reference to the kind of foods purchased and the prices paid by families of moderate income. A number of family budgets are included.

The pamphlet as a whole supplies much information regarding the living conditions of the poorer families of the working class in London.

[Luncheon for women clerks employed in the Bank of England], E. M. HARVEY (In *Minutes of Evidence taken before the Royal Commission on the Civil Service, April 10-25, 1913, with Appendices*. London: Govt., 1913, p. 95).—A brief statement regarding the improvement in health which has followed the serving of a luncheon free of cost to women employees in the Bank of England. Whereas numerous cases of neuritis in the arm or some other form of nerve trouble before this was done were prevalent, "complaints of this character are now very rare."

[**Dietaries and accounts for Poor Law Unions, England and Wales**] (*Local Govt. Bd. [Gt. Brit.], Workhouse Regulation (Dietaries and Accts.) Order, 1900, pp. 27; Rpt. Dept. Com. Local Govt. Bd. [Gt. Brit.] Poor Law Orders, 1 (1913), pp. 8, 15, 16, 37-47, 83-88*).—In the general order issued to the Guardians of the Poor of the several Poor Law Unions in England and Wales, and commented upon and in part reprinted by the committee on the revision of Poor Law Orders, regulations are given regarding dietaries and accounts and rations are outlined in detail. Brief instructions are appended to the list of rations and recipes are given for the preparation of a large number of dishes. Forms for ration accounting are also included.

Diet social service in dispensary work, F. H. KLAER (*Med. Rec. [N. Y.], 84 (1913), No. 18, pp. 792-795*).—This is an account of the results of work carried on in connection with the Social Service of the Outpatient Department and the Medical Dispensary of the Hospital of the University of Pennsylvania.

The patients or families visited by the dietitian fell into two general classes, viz, individual patients suffering with various digestive disturbances or diseases requiring special diets, and families requiring a readjustment of finances, food, and habits of eating, because of debts, malnutrition, and sickness.

Often individual cases became family cases because it was impossible to correct dietary conditions for one member without changing those of the whole household. It was not always possible to obtain satisfactory cooperation, but in the majority of cases the visitors were able to introduce noteworthy improvements in the health and also in the financial condition of the family by teaching more economical ways of buying and utilizing food as well as better methods of preparation, and thus prevented as well as cured many unnecessary cases of malnutrition.

A food clinic (*Jour. Amer. Med. Assoc., 61 (1913), No. 16, pp. 1462, 1463*).—A summary of a paper by W. M. Roach, presented at the Congress on School Hygiene, held in Buffalo, N. Y., in August, 1913. Some account is given of the favorable effects of feeding school children in Philadelphia.

Report to the local government board on bacterial food poisoning and food infections, W. G. SAVAGE (*Rpts. Local Govt. Bd. [Gt. Brit.], Pub. Health and Med. Subjs., n. ser., 1913, No. 77, pp. 80, pl. 1*).—In this digest of data the author summarizes and discusses information regarding the different kinds of food poisoning, both bacterial and that attributed to ptomaines.

According to the report, three considerations should be borne in mind, namely, the association of some outbreaks at least with actual disease of the animals whose flesh was eaten; the probability that in other outbreaks uncontaminated food had become infected from the tissues or intestinal contents of food animals in which bacterial invasion was present, as may happen when a slaughterhouse is used as a place for the preparation of sausages and similar meat foods; and that the spreading of disease by bacterial infection, when present, may be affected by lack of cleanliness and care in handling, preparing, and storing foods.

An appendix contains a list of British and continental outbreaks of food poisoning, recommendations of the local government board on outbreaks, and a bibliography.

The relation of diets and of castration to the transmissible tumors of rats and mice, J. E. SWEET, ELLEN P. CORSON-WHITE, and G. J. SAXON (*Jour. Biol. Chem., 15 (1913), No. 1, pp. 181-191*).—A generous and an insufficient diet were compared, the conclusion being that both susceptibility to transplantable tumors and the rate of growth of transplanted tumors may be influenced positively or negatively by diet—the rate of growth being slower and the number of retrogressions being higher on the low than on the normal diet.

Mixed diet and metabolism (*Med. Rec.* [N. Y.], 84 (1913), No. 17, pp. 759, 760).—This is a brief discussion of the physiological necessity of a varied diet as regards both a sufficient supply of all the nutrients and a variety of food material. The relations of a too simple diet to such diseases as diabetes and irregular gout and to anaphylaxis as shown by anemia, malnutrition, asthenia, etc., are also indicated.

The mineral content of the daily diet, HORNE-MANN (*Ztschr. Hyg. u. Infektionskrank.*, 75 (1913), No. 3, pp. 553-568).—The author found in studies with adult men that the amounts of calcium and iron oxids in a daily diet supplying 557 gm. dry matter were respectively 1.72 gm. and 156 mg. With adult women receiving 396 gm. dry matter, the corresponding values were 0.86 gm. and 91 mg., and with a 6-year-old boy receiving 325 gm. dry matter, 0.67 gm. and 57 mg. He is of the opinion that the amounts of calcium and iron supplied by the diets were sufficient.

The normal presence of boron in animals, G. BERTRAND and H. AGULHON (*Compt. Rend. Acad. Sci. [Paris]*, 155 (1912), No. 3, pp. 248-251; *abs. in Jour. Chem. Soc. [London]*, 102 (1912), No. 599, II, pp. 854, 855).—Using a method described in a previous article,^a the authors report the presence of small amounts of boron in the organs and tissues of several animals. It is the most easily detected in the hair, horns, bones, liver, and muscles.

The presence of boron in animals, G. BERTRAND and H. AGULHON (*Compt. Rend. Acad. Sci. [Paris]*, 156 (1913), No. 9, pp. 732-735; *abs. in Jour. Chem. Soc. [London]*, 104 (1913), No. 606, I, pp. 423, 424).—In continuation of the work reported in the previous article, the authors report finding boron in 27 different species of animals, and conclude that it exists normally in small amounts in the bodies of all animals, being more common in the species of marine origin.

The presence of boron in milk and eggs, G. BERTRAND and H. AGULHON (*Compt. Rend. Acad. Sci. [Paris]*, 156 (1913), No. 26, pp. 2027-2029; *abs. in Jour. Chem. Soc. [London]*, 104 (1913), No. 610, I, p. 934).—The presence of 0.08, 0.1, and 0.2 mg. of boron per liter of human, ass's, and cow's milk, respectively, and of 1 mg. per kilogram of dried material from fowl, turkey, and goose eggs is reported.

The frequent occurrence of this element in animal and vegetable products leads the authors to ask the question whether boron, like iron, may not play an indispensable part, possibly catalytic, in the living cell.

The metabolism after meat feeding of dogs in which pancreatic external secretion was absent, F. G. BENEDICT and J. H. PRATT (*Jour. Biol. Chem.*, 15 (1913), No. 1, pp. 1-35).—The increase in the total metabolism of animals and man resulting from the ingestion of food of various kinds has often been observed, and, as the authors point out, there have been two distinct theories as to the reason. One assumes that the increase in metabolism is mainly due to the mechanical processes in digestion, and the other that the increase is due to the specific dynamic action of foodstuffs, that is, that portion of the heat produced which appears as free heat and does not benefit the cells. The one attributes the increased metabolism mainly to mechanical causes; the other, to chemical processes.

Experiments on the metabolism of nitrogen and on carbon dioxid production are reported, the results showing, according to the authors, "that there is no large energy transformation incidental to segmentation, peristalsis, glandular activity of stomach, liver, and intestine, and the movement of the unabsorbed food through the intestinal tract. The attempt to explain the increased metabo-

^a *Ann. Chim. Analyt.*, 15 (1910), No. 2, pp. 45-53; *Bul. Soc. Chim. France*, 4, ser., 7 (1910), pp. 90-99.

lie in following the ingestion of food by the theory that the increase is a consequence of such movements is, therefore, not justifiable."

Some observations on metabolism in connection with an experimental march, C. H. MELVILLE, W. W. O. BEVERIDGE, and N. D. WALKER (*Jour. Roy. Army Med. Corps*, 19 (1912), No. 6, pp. 661-673, figs. 7).—Observations were made of the body weight, the amount, nitrogen content, and energy value of the food consumed, the liquids drunk, and the nitrogen eliminated in the urine and feces in the case of 3 men taking part in the march. From a study of the results obtained the authors deduct the following practical points:

"If a man has to go short of water for 1 day the effect on the water available for perspiration, that is, for temperature regulation, may persist even in a well trained man for about 48 hours." Even if "a plentiful supply of water is available on the next day [it] will only tend to increase his urinary secretion, not to redress at once the disturbance in water content of his dehydrated tissues." A similar effect results from an uneven allowance of water. "It is extremely important, therefore, to regulate the supply not only from day to day, but also in the course of every day."

The water supply of a man in an untrained condition needs more careful regulation than that of a man in good physical condition.

Report on two experimental marches carried out for the purpose of deciding a scale of field service rations; together with an account of some observations on nitrogen balance, etc. (*London: Govt.*, 1913, pp. 64+[2], pls. 7).—This blue book gives full data regarding an earlier experimental march (E. S. R., 25, p. 266) as well as the one noted above.

ANIMAL PRODUCTION.

Commercial feeding stuffs, W. J. JONES, JR., ET AL. (*Indiana Sta. Bul.* 169, pp. 71-326).—This reports analyses of the following feeds: Wheat bran, middlings, shorts, low grade flours, mixed wheat products, rye middlings, buckwheat bran, buckwheat middlings, buckwheat mixed feed, cotton-seed meal, cotton-seed cake, cotton-seed hulls, linseed meal, linseed cake, distillers' dried grains, brewers' dried grains, gluten meal, gluten feed, corn germ meal, hominy feed, corn meal, corn bran, dried sugar beet pulp, alfalfa meal, blood meal, beef scrap, tankage, proprietary stock and molasses feeds, calf meals, poultry feeds, and condimental stock and poultry feeds.

There is included a synopsis of the Indiana feeding stuffs law, together with a classification of feeding stuffs, and comments on the various feeds and their manufacture.

Use of the bitter acorn in the feeding of domestic animals, A. COURBET (*Bul. Agr. Algérie et Tunisie*, 19 (1913), No. 13, pp. 273-279).—Bitter acorns were subjected to a process of torrefaction and desiccation and thus rendered available as a palatable and nutritive feed for domestic animals. The composition of the fresh acorns is reported as follows: Water 55.3, protein 2.5, fat 3.9, carbohydrates 34.8, crude fiber 4.4, and ash 1 per cent; and the digestible nutrients as protein 2, fat 3.9, carbohydrates 31.3, and fiber 2.7 per cent.

Rations for farm stock (*Bd. Agr. and Fisheries [London]*, Leaflet 79, pp. 23).—This publication contains a general discussion of the principles of nutrition and the compounding of rations. Rations applicable to British conditions are given for dairy cows, both summer and winter feeding; for fattening cattle and sheep; for calf feeding; and for ewes, pigs, work horses, and mares with foal.

On the question of the nitrogen retention from the feeding of urea, E. GRAFE (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 86 (1913), No. 5, pp. 347-355).—

This is a continuation of work previously noted (E. S. R., 26, p. 262). In the feeding of urea to dogs and swine, the results indicated that although there was a heavy loss of nitrogen there was some nitrogen retention in the animal body.

Nutrition of the embryonic chick, I, II, III, H. W. BYWATERS and W. B. ROUE (*Jour. Physiol.*, 45 (1913), No. 6, pp. XL, XLI; 46 (1913), Nos. 2, pp. XX, XXI; 3, pp. XXXIII, XXXIV).—Investigations made of the changes occurring in the white of the egg during incubation indicate that the percentage of water diminishes at a regular rate during the earlier period of incubation, falling less regularly after the fifteenth day. There was less absorption of the protein than of the water. The ratio of coagulable to uncoagulable protein remains practically constant, ranging from 1:5.7 to 1:7.9. The presence of free sugar usually disappears after the seventh day, whereas in infertile eggs it slightly increases. The relation between the uncoagulable protein in egg white and its combined carbohydrate after different periods of incubation was found to be practically constant.

The average daily loss in weight of eggs during incubation was about 0.5 gm. It was fairly constant in the same egg, but varied greatly in different eggs. "In the case of sterile eggs, the daily loss in weight for the same egg is practically constant throughout the whole period of incubation, [but] with fertile eggs, the daily loss may fall slightly until about the middle of the period of incubation and then it begins to rise until at the end it may be half as much again as at the commencement of the incubation." It is deemed possible to ascertain the fertility of the incubating egg by studying the daily loss in weight.

It is shown that as regards the assimilation of egg white the ratio of the coagulable to the uncoagulable protein, i. e., of albumin to ovomucoid, remains practically constant. This is explained on the assumption that "the proteins of egg white are absorbed at the same relative rate, possibly by being previously converted into diffusible substances by enzymes secreted by the embryo itself."

A respiration apparatus for sheep and swine, F. TANGL (*Kísérlet. Közlem.*, 16 (1913), No. 4, pp. 467-481, figs. 7).—A report of the construction of a respiration apparatus combining the principles of the Pettenkofer-Voit, Atwater-Benedict, and Tigerstedt apparatus.

Twenty-five years of German animal production, HANSEN (*Illus. Landw. Ztg.*, 33 (1913), No. 48, pp. 442-444, figs. 4).—A résumé of the progress of animal breeding and production in Germany, in which it is shown that there has been an increase in the number of horses of 28.2 per cent, of cattle 27.7 per cent, of mutton sheep 137.7 per cent, and of goats 28.1 per cent, with a decrease in wool sheep of 69.8 per cent.

Methods of cattle raising and management under modern intensive farming (*Arb. Deut. Gesell. Züchtungsk.*, 1913, No. 17, pp. 70-93).—This is a complete review and discussion of the methods of cattle raising in operation in the Province of Saxony and portions of Prussia under the modern intensive farming system. The use of home-grown feeds and of barn feeding are emphasized. The financial cost, yields, and profits are itemized and discussed in detail.

Treatise on zootechny.—III, The bovine, P. DECHAMBRE (*Traité de Zootechnie.—III, Les Bovins.* Paris, 1913, pp. 581, pl. 1, figs. 90).—In this volume the author considers in detail the classification, origin, development, and breed characteristics of all the common breeds of cattle as well as of many rare and obsolete breeds of Europe, Asia, and South America. A special study is made of the conformation, body measurements, and ethnological characters of these breeds. There is also included a discussion of the production of beef in France,

Italy, Argentina, the United States, and other countries. The feeding, care, and management of breeding stock are treated in full, together with a study of the most approved methods of beef production. Formulas and methods for determining, by means of measurements of the animal on foot, the dressing percentage and net weight of the dressed carcass are also included.

The author discusses the selection of dairy cattle under the heads of conformation, quality, mammary system, and empirical signs or marks. Under the latter, he treats of the importance of the escutcheon as an index to milk secretion, and explains the various forms of escutcheons and hair swirls as described by F. Guenon.

Breeding cattle in French Guinea, ALDIGÉ (*Rev. Gén. Méd. Vét.*, 22 (1913), No. 259-260, pp. 337-373, figs. 5).—The native breeds of cattle of French Guinea are described and their utility value as beef and milk producers and the opportunities for improvement through the introduction of the zebu are discussed.

On the breeds, breeding, and utility value of the cattle of Dutch East Africa, G. LICHTENHELD (*Pflanzer*, 9 (1913), No. 6, pp. 261-279).—This article treats of the body measurements, breed characteristics, and utility value of the native breeds of cattle of Dutch East Africa.

The Creole cattle of Salta, T. R. GARCÍA (*Bol. Min. Agr. [Buenos Aires]*, 15 (1913), No. 6, pp. 675-682, figs. 11).—The author describes the native cattle of Argentina, commenting on their utility value and on the opportunity for improvement through the introduction of pure-bred beef sires. The three principal types of native cattle are Chaqueños, Serranos, and Fronterizos.

On beef production [in Argentina], E. LAHITTE (*Bol. Min. Agr. [Buenos Aires]*, 15 (1913), No. 6, pp. 683-689).—The author comments on the extraordinary growth and demand for Argentina meat products, and states that the abnormal demand is producing a spirit of speculation. Statistical reports of exports to the United States and other countries are presented.

The frozen meat industry of Argentina, P. BERGE'S (*An. Soc. Rural Argentina*, 1913, July-Aug., pp. 247-291, figs. 16).—This is a statistical report of the frozen meat industry of Argentina and of the export trade with foreign countries. The industry has undergone a remarkable development and growth in the past few years, and the trade now reaches throughout America, Europe, and the Orient. The relative rank of the various meat-exporting countries is given, showing that for most of the meat products Argentina leads, with Australia and New Zealand as close competitors.

Foreign meat in London, C. R. LOOP (*Daily Cons. and Trade Rpts. [U. S.]*, 16 (1913), No. 246, p. 379).—It is noted that almost the whole of the foreign supply of beef imported into the United Kingdom is now derived from Argentina and Australia. The supply from the United States diminished from 162,000,000 lbs. in 1908 to 685,000 lbs. in 1912. The average retail price for beef on the London market is estimated as follows: Sirloin, 19 cts. per pound; wing rib, 18 cts.; silver side, 16 and 17 cts.; and steaks, 24 to 28 cts.

The shrinkage in weight of beef cattle in transit, W. F. WARD and J. E. DOWNING (*U. S. Dept. Agr. Bul.* 25, pp. 78).—Shrinkage weights were obtained on cattle shipped from various points in the Southwest and Northwest. A general summary of the 3 years' work is shown in the table following.

Shrinkage on beef cattle in transit.

Class.	Number of cattle.	Average weight at origin.	Average gross shrinkage.	Average fill at market.	Average net shrinkage.	Ratio of shrinkage to live weight at origin.
		<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Pounds.</i>	<i>Per cent.</i>
Range steers in transit less than 36 hours..	197	794			29	3.65
Range steers in transit 36 to 72 hours.....	882	1,186	89	25	64	5.40
Range steers in transit over 72 hours.....	169	1,116	88	27	61	5.47
Range cows in transit less than 24 hours....	1,724	838	60	30	30	3.58
Range cows in transit 24 to 36 hours.....	1,551	896	70	39	31	3.46
Range cows in transit 36 to 72 hours.....	275	1,034	96	46	50	4.84
Range cows in transit over 72 hours.....	177	1,010	70	30	40	3.96
Mixed range cattle in transit less than 24 hours.....	1,511	700	37	22	15	2.14
Mixed range cattle in transit 24 to 36 hours..	872	848	72	18	54	6.37
Mixed range cattle in transit 36 to 72 hours..	622	954	76	39	37	3.88
Mixed range cattle in transit over 72 hours..	988	729	80	29	51	7.00
Range calves in transit less than 24 hours..	773	185	6	7	+1	+ .59
Range calves in transit over 24 hours.....	772	193	6	11	+5	+2.45

Beet-pulp-fed cattle in transit 38 to 120 hours.....	2,614				54	

It is concluded from these investigations that "the shrinkage of cattle in transit depended very materially upon (a) the conditions existing at the time of shipping and upon the treatment received during the drive to the loading pens; (b) the length of time the cattle were held without feed and water before being loaded; (c) the nature of the fill which the cattle had before loading, a great loss in weight being experienced with succulent grass, beet pulp, or silage; (d) the weather conditions at the time of loading and while in transit; (e) the character of the run to market, slow, rough runs causing a greater shrinkage; (f) the kind of treatment they received at unloading stations; (g) the time of arrival at market, the fill being small if they arrived just before being sold, and cattle that were shipped a long distance and arrived at market during the night usually not filling well; whereas if they arrived the afternoon before or about daylight of the sale day, they generally took a good fill; and (h) the climatic conditions at the market.

"An exceedingly large fill at market is not desired as it will detract from the selling price. The shrinkage on calves may seem small, but under normal conditions it holds about the same proportion to their weight as is found with grown cattle. The difference between the shrinkage of cows and steers is not as great as is ordinarily supposed. Steers will usually shrink somewhat less than cows of the same weight. The shrinkage during the first 24 hours is greater proportionately than for any succeeding period of the same duration. The shrinkage of cattle was found to vary in direct proportion to their live weight when conditions were the same and all other factors were equal. The shrinkage of range cattle in transit over 70 hours during a normal year is from 5 to 6 per cent of their live weight. If they are in transit 36 hours or less the shrinkage will range from 3 to 4 per cent of their live weight. The shrinkage of fed cattle does not differ greatly from that of range cattle for equal periods of time. It varied from about 3 per cent with all of the silage-fed cattle

and 4.2 per cent with the corn-fed cattle, when both classes of these animals were in transit for less than 36 hours, to 5.4 per cent for the pulp-fed cattle which were in transit from 60 to 120 hours. Cattle fed on silage have a large gross shrinkage but usually fill so well at the market that the net shrinkage is small. Pulp-fed cattle shrink more in transit than any other class of cattle, and also present a greater net shrinkage.

"The shrinkage on cattle is proportionately smaller for each 12 hours they are in transit after the first 24-hour period is passed. For a long journey the common method of unloading for feed, water, and rest is to be preferred to the use of 'feed and water' cars. Cattle should be weighed before being loaded wherever practicable, since a comparison of this weight with the sale weight will show the net shrinkage. Moreover this weight at point of origin may be of material benefit to the shipper in case of a wreck or a very poor run to market."

Sheep farming in North America, J. A. CRAIG (*New York, 1913, pp. XVIII+302, pls. 25, figs. 3*).—The chapters included in this book, which is one of the Rural Science Series, are the position of sheep in profitable farming; sheep farms and their equipment; breeds of sheep; formation and improvement of the flock; seasonal management; lambing; fattening; preparation of sheep for show; and diseases.

Boulonnaise breed of sheep, J. TRIBONDEAU (*Jour. Agr. Prat., n. ser., 26 (1913), No. 32, pp. 180, 181, pl. 1*).—This is a brief description of this breed of sheep and its distribution throughout France and portions of Europe. Its characteristics are hardiness and rustling and pasturing qualities, and its improvement and promotion is recommended.

Fitting yearling wethers and lambs for exhibition, G. C. HUMPHREY and F. KLEINHEINZ (*Wisconsin Sta. Bul. 232, pp. 26, figs. 12*).—This bulletin is intended as a practical guide in the selection, fitting, and showing of yearling wethers and lambs for exhibition, but also reports experimental work in feeding.

In order to study the value of the various grain rations during two 3-year fitting periods wethers intended for exhibition at the International Stock Exposition were divided each year into 4 lots as uniform as possible with reference to breed, size, and general quality. They were fed alike as to pasture, hay, cabbage, and roots. Grain feeding began August 1 and continued to the latter part of November.

The results of these feeding operations are summarized as follows: "The wethers fed peas, oats, and bran were awarded first place in the carcass competition between the various lots each of the 3 years of the second period, and were also awarded the largest number of individual prizes at the show. Though peas were comparatively expensive, they produced firm flesh of high quality and also made good gains. They are therefore highly recommended for show fitting when fed in combination with oats and bran. Barley, oats, and bran ranked second in the carcass competition between the lots, and also in number of individual prizes awarded in the open classes. Barley and oats stood third in point of prizes won at the show and also ranked third in the carcass competition. This ration produced the lowest gains of any fed during the second period. Corn, oats, and bran, and corn and oats produced the largest and most economical gains, but, with a few exceptions, the wethers fed this ration were inclined to be soft and overdone. Carcasses from the lot fed corn, oats, and bran were never awarded prizes in the regular carcass classes. Whole oats fed alone are a most excellent feed for sheep which are well advanced in flesh, but as a rule, for sheep being fitted for fat classes, they are too bulky to insure the desired finish."

A former reference has been made to results obtained during the first 3-year period (E. S. R., 18, p. 263).

Cassava for pigs, J. L. FRATEUR and A. MOLHANT (*Min. Agr. et Trav. Pub. [Belgium], Off. Rural Raps. et Communs., 1913, No. 5, pp. 87-118, fig. 1*).—Four pigs 2½ years old each fed a daily ration of 2.02 kg. of cassava, 2.02 kg. of a mixture of bran and low-grade flour, 1.6 kg. of mangels, and 0.18 kg. of meat meal for 77 days made a daily gain per head of 0.53 kg. (1.17 lbs.). In another test 5 pigs each fed a daily ration of 1.47 kg. of cassava, 1.47 kg. of the bran-flour mixture and 4.99 kg. of skim milk for 58 days, made a daily gain per head of 0.67 kg., and a similar lot 0.62 kg. per head. Methods and results of analyses of cassava by J. Van Buggenhout et al. are given.

Trials with weights of fattening swine and the "plucks" from these, E. HOLM (*Ber. K. Vet. og Landbohøjskoles Lab. Landökonom. Forsög [Copenhagen], 82 (1913), pp. 32, figs. 2*).—The average slaughter weight of 400 swine at 3 Danish slaughter houses was 70.8 kg. (warm) and 69.3 kg. (cold), and of the plucks (internal organs and offal) 4 kg. (warm) and 3.9 kg. (cold).

Treatise on zootechny.—II, The horse, P. DECHAMBRE (*Traité de Zootechnie.—II, Les Équidés. Paris, 1912, pp. 494, figs. 68*).—The first part of this book treats of the zoological classification, body conformation, measurements, and race characteristics of domestic animals. The author draws attention to the fact that races or breeds are characterized by their rectilinear outlines, especially the facial profile; that variations in morphology are noted in the cephalic and body form and in the external features, such as weight, color, horns, hair, wool, or plumage; and that in general there is a harmony or coordination of parts.

In the second part he takes up a study of the breeds of horses, classifying them under 3 groups, viz, those with a flat frontal or profile, those of concave frontal, and those of convex profile. These groups are further subdivided and classified. There follows a discussion of the origin, development, breed characteristics, distribution, and utility value of the different breeds of horses. The breeds included in this study are those of Arabia and Asia, Russia and Finland, Bohemia and Tunis, the Percheron, the Clydesdale, the ponies of England and Europe, the Belgian, the Shire, the Suffolk, and a number of the rare breeds of Asia and Europe. There is also given a discussion of the "demi-sang" or grades of England and France, among which are included the army remounts, the hunters, hackneys, and cobs, the Cleveland Bay, and the Irish half-breed.

The author also discusses the various breeds and types of mules and asses, both in Europe and in Asia, and discusses their production from the utility standpoint. There are included several chapters on the feeding, care, and management of breeding stock; and a discussion of the problems connected with the improvement of the military remount service and the government stud.

Did the horse exist in America at the time of the discovery of the New Continent? E. TROUSSART (*Rev. Gén. Sci., 24 (1913), No. 19, pp. 725-729*).—In answer to this query the author offers as proofs of the early existence of the American horse (1) the records of history dating back to the Spanish conquest of Mexico, at which time native horses were discovered here; (2) evidences from geology and paleontology which point to a very primitive type of horse; and (3) the physiography of the country and the character of American animals, which indicate that America's close proximity to Asia facilitated the introduction of the horse from that continent.

The feeding of farm horses (*Dept. Agr. N. S. Wales, Farmers' Bul. 64, pp. 26*).—The first portion of this publication contains general information on horse feeding, condensed from Henry's Feeds and Feeding and other sources. Reports are then given from the principal of the Hawkesbury Agricultural Col-

lege and the managers of experiment farms throughout the State, describing the methods of horse feeding in use at these stations. The information given is of an entirely practical nature, outlining the rations fed and the methods of care and management, including notes on the treatment of horses for colic.

Horse feeding experiments with dried beer yeast, O. VON CZADEK (*Ztschr. Landw. Versuchs. Österr.*, 16 (1913), No. 9, pp. 879-889).—This product proved to be a palatable laxative feed, and especially adaptable as a supplement to oat feeding.

Cotton-seed meal as a feed for laying hens, J. K. MORRISON (*Mississippi Sta. Bul.* 162, pp. 11, figs. 9).—This bulletin is a preliminary report of experiments in progress. Results of 6 months' work tend to show "that cotton-seed meal used as the chief source of protein is palatable to fowls, and that when fed judiciously on it they will produce eggs; that hens fed on cotton-seed meal will produce eggs when eggs are highest in price; that as far as can be determined the general condition of the cotton-seed meal-fed fowls seems just as good as the condition of those fed on beef scrap; that the tendency was to loose flesh and not get overfat, although the fowls were allowed access to the feed at all times; and that there is a good margin of profit from hens when given a properly balanced ration."

Poultry notes, 1911-1913, R. PEARL (*Maine Sta. Bul.* 216, pp. 141-168, figs. 9).—This bulletin includes a general consideration of the following items: The value, method of preservation, and economical use of hen manure; plans for the construction of a concrete manure shed costing approximately \$185; the value and method of construction of a crematory for dead poultry; the making of an improved range feed trough; methods for the protection of poultry against hawks, crows, rats, and other natural enemies; and the value and method of providing green feed for poultry.

The results of technical studies relating to the formation of the egg and previously reported from another source (*E. S. R.*, 26, p. 670) are given.

Mardi Gras poultry in France, E. BROWN (*Country Gent.*, 78 (1913), No. 42, pp. 1543, 1544, figs. 3).—The author describes the preparation of fancy poultry for the Mardi Gras festival of France. The Bresse fowl stands in highest favor, being a light-boned bird with excellent fattening qualities and of a delicate flavor. La Flèche is a larger and somewhat heavier boned breed, but carries abundant meat, which is of a fine texture. Du Mans stands next in favor, being fine and white of skin, abundantly fleshed, and of excellent quality. The Crèveceur fowl is compact, broad, and deep, but lacking in quality. The Courtes Pattes fowl is a delicacy, largely because of its quality, texture, and fine flavor.

Breeders' and cockers' guide, F. R. GLOVER (*Liste, N. Y.*, 1913, pp. 109, figs. 7).—This booklet treats of the breeding, feeding, care, and management of the breeds of poultry used for fighting and pit purposes.

The national standard squab book, E. C. RICE (*Boston*, 1913, 4. ed., pp. 416, figs. 200).—This is a practical manual giving complete directions for the installation and management of a squab plant.

DAIRY FARMING—DAIRYING.

Some practical results of feeding experiments, J. B. LINDSEY (*Massachusetts Sta. Rpt.* 1912, pt. 2, pp. 56-64).—Dairy cows were fed a ration of hay, bran, gluten feed, and raw potatoes, the latter being fed in increasing amounts of from 10 to 50 lbs. per day. The addition of potatoes in 2 out of 3 cases not only checked the natural shrinkage in milk yield but actually increased the flow. It is concluded from these experiments that when potatoes are cut and fed in amounts up to 25 lbs. per head daily they in no way affect the

health of the animal or the yield of the milk. Foreign observations on the feeding of potatoes to steers, oxen, milch cows, dry cows, sheep, and horses are referred to.

The use of molasses and molasses feeds for farm stocks is also discussed.

The food value of plain and molasses beet pulp, J. B. LINDSEY (*Massachusetts Sta. Rpt. 1912, pts. 1, pp. 129-140; 2, pp. 64-66*).—Six cows were fed by the reversal method in periods lasting 5 weeks on a basal ration of hay, bran, and cotton-seed meal to which was added 4.3 lbs. of either corn meal or of beet pulp daily.

The herd lost in live weight 33 lbs. on the corn meal ration and gained 37 lbs. on the beet pulp ration. There was no substantial variation in the yield or average composition of the milk. It required for the corn meal ration 112 lbs. dry matter to produce 100 lbs. of milk, and 20.51 lbs. to produce 1 lb. of milk fat; for the beet pulp ration 110.72 lbs. and 20.54 lbs., respectively.

In a similar experiment to the above molasses beet pulp and corn meal were compared. The amounts of digestible nutrients in each ration were approximately the same. The herd gains were similar. There was no wide variation in milk yields and only a slight advantage in the production of milk fat with the corn meal ration. It required for the corn meal ration 104.4 lbs. dry matter to produce 100 lbs. of milk and 18.72 lbs. to produce 1 lb. of fat; for the molasses beet pulp ration 108.1 and 19.87 lbs., respectively.

The value of oats for milk production, J. B. LINDSEY (*Massachusetts Sta. Rpt. 1912, pts. 1, pp. 141-153; 2, pp. 52-55*).—Three experiments were conducted in which 2 lots of 2 cows each were fed for alternate periods of 4 weeks each, with 1 week between periods, on like amounts of a basal ration of hay and bran to which was added a like amount of either corn meal or ground oats.

The average gain made in live weight with both systems was practically the same, and the yields of milk and of milk ingredients were nearly identical. However, it is believed that the allowance of the basal ration was too large, thus furnishing an excess of nourishment and tending to invalidate the results of the experiment.

The feed cost of milk and of milk fat was for the corn meal ration \$1.40 per 100 lbs. of milk and 24.5 cts. per pound of fat; and the oat ration \$1.46 per 100 lbs. of milk and 25.6 cts. per pound of fat. "While oats are a valuable food, it is not believed they can usually be fed economically to dairy animals in Massachusetts."

Feeding experiments with milch cows, A. CARLIER (*Min. Agr. et Trav. Pub. [Belgium], Off. Rural Raps. et Communs., 1913, No. 5, pp. 39-50*).—This gives detailed data concerning 2 experiments conducted in 1912 and a summary of 4 years' experiments in which comparisons were made of the feeding value of cotton-seed meal and coconut meal. On the whole, it was found that cotton-seed meal was more advantageous from the standpoint of milk production but that coconut meal apparently produced a slightly richer milk and more butter.

Niger cake for milch cows, E. WARSAGE (*Min. Agr. et Trav. Pub. [Belgium], Off. Rural Raps. et Communs., 1913, No. 5, pp. 51-54*).—On a ration of hay, straw, mangels, bran, and wheat 2 cows for 5 days before and 10 days after an experimental period of 30 days gave a daily average per cow of 8.17 liters (about 8.6 qt.) of milk testing 2.59 per cent of fat. During the 30-day period in which the above ration was supplemented with from 1 to 2 kg. of niger cake the average milk production was 8.5 liters testing 3.08 per cent fat. The cows gained 13 kg. and 36 kg., respectively, in weight during the 30 days. An analysis of the niger cake is given.

Feeding experiments with hay and varying amounts of protein feeds for the dairy cow, J. J. OTT DE VRIES (*Verlag Ver. Exploit. Proefzuivelboerderij Hoorn, 1912, pp. 15-37*).—In these experiments the protein-rich feeds proved more expensive without yielding an appreciable increase of milk over the protein-poor feed, and resulted in a lower milk fat percentage.

North Carolina dairy herd records, W. H. EATON (*Bul. N. C. Dept. Agr., 34 (1913), No. 5, pp. 30, figs. 5*).—Yearly tests of 14 North Carolina dairy herds, comprising in all 144 cows, are reported.

Comparing the economy of production as between large and moderate producers, it was found that the cows averaging 374 lbs. of milk fat per annum gave annual profits of \$68.71 per cow, and produced milk fat at a cost of 17 cts. per pound, while cows averaging 165 lbs. of milk fat gave profits of \$19.85, and the milk fat cost 25 cts. per pound.

Report of the Richmond-Lewiston Cow Testing Association, W. E. CARROLL (*Utah Sta. Bul. 127, pp. 193-242, figs. 8*).—During a 2 years' test, involving 26 herds, the average yearly milk yield of the highest herd was 9,685 lbs., and the lowest 4,916 lbs.; the corresponding average yields of milk fat were 230.1 and 197 lbs. During this period the average cost of feed for the highest producing herd was \$44.19 per year; for the lowest \$34.21, while the profit realized from the former was \$69.96, and the latter \$33.61. A wide variation was found in the yield of milk fat and net returns between cows in the same herd. The difference in milk-fat between the most and least profitable cow in each herd ranged from 40.07 to 324.7 lbs.

In studying the effect of length of lactation period upon total milk-fat yield it was found that beginning with a dry period of 2 months the yield gradually decreased from 272.7 to 121.7 lbs. when the cows were dry 6 months or over during the year. No correlation was noted between the amount of fat produced the first month and the annual record. Dairy-bred cows led the scrubs in yearly production and in amount of fat given the first month of lactation and showed a decided tendency toward a longer lactation period. The data indicated that a cow for highest production should be dry longer than one month, but that a rest longer than 2 months adds nothing to her powers of production. Lactation periods of various lengths from 7 to 18.5 months, provided they are preceded and followed by normal dry periods in all cases, seemed to yield the same fat and profit in any given length of time.

Cows freshening in the fall produced on the average 45.1 lbs. more fat and returned \$9.43 more profit above cost of feed during the next 12 months than cows freshening in the spring. The cost of feed was \$5.33 more per head for the cows calving in the fall.

The highest producers were the most profitable. There was a uniform decrease in net returns with a decreasing milk-fat production.

Dairy industry in northern Europe, G. GUITTONNEAU (*Ann. Inst. Nat. Agron., 2. ser., 12 (1913), No. 1, pp. 41-178, figs. 35*).—Part 1 of this report gives the results of a study of the dairy industry in north Germany, Denmark, the Netherlands, and Sweden. In a study of the milk supply of large cities the author deals especially with Copenhagen and Stockholm. In a chapter on the manufacture of butter and cheese descriptions are given of a number of creameries and of the newer forms of creamery equipment and machinery. Notes are also given on the manufacture of casein, milk sugar, and powdered milk.

Part 2 deals with the organization of the export trade in milk products in the Netherlands, Denmark, and Sweden.

Report of the sanitary inspector of the State of Idaho, 1911-12, J. H. WALLIS (*Bien. Rpt. Idaho Dairy, Food and Sanit. Insp. and State Chem., 5*

(1911-12), pp. 19-32, 129-153, pls. 4).—This is a report on the analysis and condition of samples of commercial butter, cream, milk, ice cream, and condensed milk. There is also included a statistical report on the number of cows milked, the average yield, grade of stock, stock water supply, and the scoring of a number of Idaho dairy farms.

Report of the feed and dairy section, P. H. SMITH (*Massachusetts Sta. Rpt. 1912, pt. 1, pp. 118-128*).—This includes the text of an act to regulate the use of utensils for testing the composition or value of milk and cream; also a summary of inspection work with glassware, etc.

The ductal system of the milk glands of the bovine, O. WIRZ (*Arch. Wiss. u. Prakt. Tierheilk., 39 (1913), No. 4-5, pp. 375-421, figs. 7*).—This is an elaborate treatise on the anatomy of the milk glands and the nature of milk secretion in the bovine, dealing with the constitution and function of the alveoli, the relation of milk secretion and the blood streams, the ductal system and its functions, the occurrence of leucocytes, the consistency of the udder, and the size and nature of the milk cistern. A bibliography of 25 references is appended.

[**Factors affecting the composition of milk**], J. AUROUSSEAU and L. J. PONSCARME (*Ann. Ecole Nat. Agr. Grignon, 3 (1912), pp. 73-106*).—This is a series of papers on the composition of milk from the standpoint of milk inspection, as follows:

Influence of feeding stuffs on the composition of milk (pp. 73-81). Two cows on pasture supplemented with hay, bran, mangels, and linseed cake, with straw ad libitum, for 5 days gave a daily average of 15 liters (about 15.9 qt.) of milk each, containing 4.43 per cent milk fat and 9.03 per cent solids-not-fat. The supplemental feeds were then withheld and the cows had the run of pasture with straw ad libitum for 6 days, during which their average milk production was 18.6 liters each, containing 3.53 per cent fat and 8.74 per cent solids-not-fat. These results were confirmed in a test with 4 cows the following year. In another test with 4 cows for 3 days on a ration of dry fodders, bran, and scant pasture, the average daily milk yield per cow was 10.37 kg. with an average composition of 4.02 per cent milk fat and (the first and third days only) 9.13 per cent solids-not-fat. These cows were then fed a ration of turnips with oat straw ad libitum for 6 days, during which their average milk production was 12.35 kg. each with an average composition of 3.5 per cent milk fat and 8.77 per cent solids-not-fat.

Composition of first and last drawn milk (pp. 87-90). Analyses are reported of the first and last portions of milk drawn into separate receptacles. Of the first half of 2 milkings the fat content was 1.51 per cent, the solids-not-fat 9.45 per cent. The corresponding percentages for the last half of the 2 milkings were 4.86 and 9.04.

Influence of spontaneous creaming on the composition of milk (pp. 91-96). In a test with 5 liters of fresh milk testing 3.9 per cent fat and 9.08 per cent solids-not-fat, a sample of 1 liter poured off at the end of 1½ hours tested 4.5 per cent fat and 8.78 per cent solids-not-fat. A second liter poured off at the end of 2½ hours tested 3.8 per cent fat and 9.19 per cent solids-not-fat. Two liters poured off at the end of 3½ hours tested 4.35 per cent fat and 8.87 per cent solids-not-fat. The remaining milk tested 2.5 per cent fat and 9.65 per cent solids-not-fat. In another test the milk remaining after the withdrawal of the third sample tested 2.2 per cent less fat than the original milk. This milk, after being subjected to these 2 tests, was heated to 30° C. and the test repeated. After the withdrawal of the third sample the remaining milk tested only 0.4 per cent less in fat than the original milk.

Influence of potassium bromid on the composition of milk (pp. 97-106). Doses of 20, 25, and 30 gm. of potassium bromid fed to cows had no appreciable

effect on the quantity or fat content of the milk. The bromid was found in the milk 14 hours after ingestion and for more than 2 days after the last dose. In another test with 2 cows the ingestion of 60 gm. of potassium bromid was followed by diminished milk production and a reduction of fat content. This reaction was rapid, in no case persisting for more than 36 hours after the dose. After the effects of the bromid had passed off the fat content of the milk rose rapidly above the normal, indicating that potassium bromid has a restraining effect on fat secretion. Complete analyses are given of these milks before and after the ingestion of bromid.

The viscosity of cream, F. K. M. DUMARESQ (*Proc. Roy. Soc. Victoria, n. ser.*, 25 (1913), No. 2, pp. 307-322, figs. 5).—Results of experiments testing the viscosity of cream under different conditions are summarized as follows:

"(1) The main factors instrumental in varying the viscosity of cream are acidity, temperature, and fat content, and of these three the first holds the most important place. (2) An increase in acidity produces very little effect on viscosity of cream, up to the 'critical point,' at which a sudden sharp rise in viscosity occurs. (3) The change in viscosity of separated milk at the degree of acidity corresponding to the 'critical acidity' of cream is very slight, i. e., for separated milk there is no critical acidity, proving that this is a property of the fat globule, or rather of its envelope. (4) An increase in temperature of cream diminishes its viscosity, at first rapidly, afterwards at a slower rate. (5) The viscosity of cream is a quadratic function of the fat content, if the other factors remain constant."

On the influence of different factory methods on the water content of the curd of Edam cheese, W. VAN DAM (*Verlag Ver. Exploit. Proefzuivelboerderij Hoorn, 1912, pp. 84-91*).—In these tests the moisture content ranged from 46.8 to 52 per cent. Poorly coagulated curd tested higher than normal curd. The addition of calcium chlorid increased the moisture content, whereas longer standing reduced it. Working the curd at a high temperature, 29° C. (80.6° F.), resulted in a higher moisture test than working at 26.6°. A low heating temperature, 33.5°, was also conducive to a higher moisture test.

On the faulty "Knijpers" in Edam cheese, F. W. J. BOEKHOUT (*Verlag Ver. Exploit. Proefzuivelboerderij Hoorn, 1912, pp. 92-102*).—The diseased condition sometimes found in Edam cheese affected with cracks or faulty formation is known as "Knijpers." The cracks or rents occur as the result of the formation of gases due to a bacterium which has been isolated. As a preventive for the occurrence of this gas the addition to the cheese of a small quantity of potassium nitrate is suggested.

Wensleydale cheese, MISS G. N. DAVIES (*Jour. Agr. [New Zeal.]*, 7 (1913), No. 2, pp. 147-149).—Directions are given for the manufacture of Wensleydale cheese, which is described as a very mellow, rich, finely flavored, and blue molded cheese, resembling the Stilton variety.

Some investigations of parchment paper, S. HALS and S. HEGGENHAUGEN (*Norsk Landmandsblad*, 32 (1913), No. 31, pp. 369-371).—The results of chemical and physical examinations of a dozen samples of parchment paper used for dairy purposes are given and discussed. The determinations included color, smoothness of surface, weight per square meter, ash in paper and in water-soluble substances, total water-soluble substances, sugar, boric acid, magnesium chlorid, and moisture. Seven of the samples contained from 14.2 to 26 per cent of water-soluble substances, and 4 contained from 13.2 to 14.5 per cent of reducing sugars.

VETERINARY MEDICINE.

Report of the civil veterinary department, Eastern Bengal and Assam, for the year 1910-11, W. HARRIS (*Rpt. Civ. Vet. Dept. East. Bengal and Assam, 1910-11, pp. 2+28+2*).—This report includes an account of the occurrence of the more important diseases of animals, preventive inoculations, breeding operations, etc.

Report of the civil veterinary department, Assam, for the year 1912-13, S. G. M. HICKEY (*Rpt. Civ. Vet. Dept. Assam, 1912-13, pp. 3+23+1*).—A report similar to the above.

The diagnosis of newly lactating animals according to Schern's method, E. WEBER (*Ztschr. Tiermed., 17 (1913), No. 5, pp. 205-209*).—Following studies of Schern's method (E. S. R., 21, p. 614) the author states that if an initial milk decolorizes the formaldehyde methylene blue solution (Schardinger's reagent) within 10 to 12 minutes, it may be concluded that it comes from an animal in an advanced state of lactation. If the reagent is not decolorized, however, or if the milk contains strippings, no conclusion can be drawn.

The use of pituitary extract in bovine and equine obstetrics, H. SCHMIDT and M. KOPP (*Abs. in Vet. Rec., 26 (1913), No. 1316, pp. 199, 200*).—This is a report of six cases in which very satisfactory results were obtained.

Serum-therapy in practice, A. R. MENARY (*Amer. Vet. Rev., 43 (1913), No. 3, pp. 284-286*).—This details the author's experiences in tuberculin testing and with antistrangles vaccine, canine distemper bacterin, blackleg vaccine, polyvalent bacterins, and hog cholera vaccine.

Natural variation of *Bacillus acidi lactici* with respect to the production of gas from carbohydrates, J. A. ARKWRIGHT (*Jour. Hyg. [Cambridge], 13 (1913), No. 1, pp. 68-86*).—"A bacillus belonging to the *B. acidi lactici* group has been repeatedly isolated during 11 months from the urine of one patient, and no other Gram-negative bacillus has been found in the same urine during this period. The bacillus has occurred in 2 varieties which differed as regards gas formation only. Variety I formed gas from sugars and alcohols, and Variety II formed acid and no gas from the same sugars and alcohols. The 2 varieties gave identical serum reactions both as regards agglutination and absorption of agglutinins with specific sera prepared from rabbits immunized with the respective varieties. Intermediate varieties as regards gas production also occurred, but were not constant when subcultured. Varieties I and II remained constant in their characters after 4 months' subculture on broth and agar. Variety II, which at first did not produce gas from sugars, was induced to do so by first growing in a solution of sodium formate in broth."

The action of the protein poison on dogs: A study in anaphylaxis, C. W. EDMUNDS (*Ztschr. Immunitätsf. u. Expt. Ther., I, Orig., 17 (1913), No. 2, pp. 105-134, figs. 4*).—This article indicates that the symptoms produced by the injection of the poisonous portion of the protein molecule are practically the same as those which are noted in acute anaphylaxis, with the exception that in the last-named case the blood loses its coagulating power.

About the specificity and the diagnostic value of the Ascoli thermoprecipitin reaction for detecting hematic carbuncle and erysipelas, G. FINZI (*Centbl. Bakt. [etc.], 1. Abt., Orig., 68 (1913), No. 5-6, pp. 556-562*).—The author concludes that the thermoprecipitin reaction has no specific value for the diagnosis of either hematic carbuncle (anthrax) or erysipelas. Extracts of the organs of animals affected with carbuncle give a zonal reaction with a specific erysipelas serum, and derivatives of the *Bacillus suispestifer* and the products of the Preisz-Nocard bacillus also show a specific reaction. Sera from sound horses, heated from 6 to 12 to 48 hours at from 55 to 56° C.,

react with the organ extracts from animals affected with anthrax, as do also normal sera of bovines, rabbits, and guinea pigs. Egg white behaves toward the derivatives in the same way.

A specific reaction can be obtained with extracts of the epiploon, heart, liver, or spleen of guinea pigs affected with carbuncle. The extracts of the epiploon were more active than those of the spleen.

Thermoprecipitation in anthrax, Z. SZYMANOWSKI and J. ZAGAJA (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 12 (1912), No. 3, pp. 256-265; *abs. in Ztschr. Immunitätsf. u. Expt. Ther.*, II, Ref., 6 (1913), No. 8, p. 719).—A group of animals is described in which 69 were suspected of having anthrax. Of these, 33 gave a positive and 22 a negative precipitin test. These findings were verified by the bacteriological examination. In 11 cases the thermoprecipitin reaction showed positive when the bacteriological test showed negative, but in only 3 cases did the thermoprecipitin test show negative when positive results were found bacteriologically.

Anthrax vaccination, its use and abuse, J. A. GOODWIN (*Amer. Vet. Rev.*, 43 (1913), No. 3, pp. 267-275).—This discusses the reasons for failure in anthrax vaccination, the kinds of animals to vaccinate, points to be considered in immunizing animals, impotency of some vaccines, the advisability of hyperimmunizing animals, abuse of anthrax vaccination, and the promiscuous distribution of vaccines and other biological products by unreliable parties.

Feeding experiments with the virus of infectious bulbar paralysis, S. VON RÄTZ (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 13 (1913), No. 1-2, pp. 1-7).—The experiments showed that the virus of this disease may be ingested by mice and Carnivora in infected food and the disease produced in this way. Five of 11 cats and dogs fed upon virulent material died.

The relationship between the paratyphoid infections in man and in animals, D. A. DE JONG (*Rev. Gén. Méd. Vét.*, 22 (1913), No. 255-256, pp. 117-123; *abs. in Jour. Compar. Path. and Ther.*, 26 (1913), No. 3, pp. 266-268).—The author concludes that "bacterial diseases of animals slaughtered for meat can only be considered as the cause of meat poisoning in very exceptional cases. The organisms in question occur in nature as saprophytes and are to some extent excreted by diseased or healthy men and animals (carriers). They can be found normally in healthy men and animals. In such cases they may be the cause of secondary infections. They can infect the carcasses or animal products of even healthy animals, but more particularly the carcasses and products of diseased animals, because these form a particularly favorable culture medium for the organisms."

Some peculiar and probably specific bodies in the erythrocytes in rinderpest and another allied disease, W. L. BRADDON ET AL. (*Parasitology*, 6 (1913), No. 3, pp. 265-275, pl. 1).—The bodies here described have been invariably found by the author in all cases of typical acute rinderpest during the febrile stages and in the great majority of the cases for long periods up to 8 months after recovery has taken place.

"The occurrence of a body of special, and within certain limits, uniform morphology has been demonstrated in the red corpuscles of animals affected with rinderpest. The movements of the body, the evidence of its growth *pari passu* with the development of the disease, and above all its reproduction in animals in which it was not previously present on the inoculation of material containing it, are evidence of its being a living and independent organism. Its detected presence (so far) only in animals which at the time have, or which probably have had, rinderpest recently, and its entire absence from animals highly susceptible to the disease, but known not to have had it or to have been exposed to infection, affords a presumption that the body is specifically related

to the disorder, or in other words represents a stage in the life history of the specific infective agent; or, it may be, a culture form . . . The specific body resembles no parasite of which the life history is so far known . . .

"The second body described affords evidence of the existence of a second specific complaint which may be and probably has been in the past confused with true rinderpest. It would be important to determine if animals affected by the second complaint when they have recovered are still susceptible to true rinderpest. The second body also is a new form."

About a supposed neutralization of the activity of tetanus toxin by neurin or betain, V. ADSESEN (*Ztschr. Immunitätsf. u. Expt. Ther.*, I, Orig., 17 (1913), No. 2, pp. 135-140).—Either neurin or betain hydrochlorid is capable of neutralizing tetanus toxin, but this is not due to any specific property of the two substances but rather to the inhibition of an acid or an alkali. If an acid or an alkali is added to tetanus toxin, no toxic results are produced.

On "tick paralysis" in sheep and man following bites of *Dermacentor venustus*, with notes on the biology of the tick, S. HADWEN (*Parasitology*, 6 (1913), No. 3, pp. 283-297, pls. 2).—"Tick paralysis" occurs in British Columbia and affects man, sheep, and probably other animals. The disease is caused by the bites of *D. venustus*. It is usually of short duration, is benign in character, but occasionally it persists for long periods, and may terminate fatally. From an economic point of view the disease is of some importance to the sheep industry. The causative agent has not been discovered, and the disease has not been reproduced by inoculation. The most likely hypothesis is that the tick injects a toxin which gives rise to symptoms appearing coincidentally with the complete engorgement of the tick. In three consecutive cases, experimentally produced by me in lambs, paralysis occurred 6 to 7 days after the ticks were put on. In no case did I fail to produce paralysis through the agency of the tick bites. It has been proved that *D. venustus* usually bites sheep along the backbone; possibly the point of attachment may have some bearing on the symptoms or severity of the case."

Experimental "tick paralysis" in the dog, S. HADWEN and G. H. F. NUTTALL (*Parasitology*, 6 (1913), No. 3, pp. 298-301).—This is a report of experiments in which "tick paralysis" was experimentally produced in a dog at Cambridge through the application of a single *Dermacentor venustus* female from Canada. The disease is said to be the same as that observed in sheep and described in the paper above noted. The examination of the dog's blood proved negative.

The chemistry of tuberculin, G. LOCKEMANN (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 73 (1911), No. 5, pp. 389-397; *abs. in Centbl. Bakt. [etc.]*, 1. Abt., Ref., 52 (1912), No. 1-2, pp. 37).—If tubercle bacilli are grown in a medium containing asparagin as the only source of nitrogen, protein-like substances are developed in the culture medium which are supposed to originate from the tubercle bacillus; consequently the author believes that the metabolic products elaborated by the tubercle bacillus are somewhat dependent upon the make-up of the medium in which they are cultivated.

Contribution to the chemistry of the tubercle bacillus.—A preliminary report, E. LÖWENSTEIN (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 68 (1913), No. 7, pp. 591-593).—As an initial step in determining whether the composition of tuberculin was dependent upon the nutrient solution used for cultivating the tubercle bacillus, an attempt was made to find a simpler nutrient solution than has heretofore been used for preparing tuberculin. A nutrient solution composed of ammonium phosphate, glycerin, and distilled water was prepared and inoculated with the tubercle bacillus. Some controls received an addition of 0.4 per cent of either sodium chlorid, potassium chlorid, or potassium sulphate.

The greatest growth was noted in the ammonium phosphate flask. The flask containing the sodium chlorid in addition showed a lesser growth, but it was greater than the flask containing potassium chlorid; consequently the presence of potassium, sodium, chlorin, or sulphur is deemed unnecessary for the growth of the tubercle bacillus. The synthetic tuberculin so obtained was found to be as active as that prepared in an asparagin medium.

Experiments in regard to the inhalation of tuberculous material from man by the cat, P. CHAUSSE (Compt. Rend. Soc. Biol. [Paris], 72 (1912), No. 2, pp. 50-52; abs. in Centbl. Bakt. [etc.], 1. Abt., Ref., 52 (1912), No. 14, p. 426).—The inhalation tests, which are a continuation of those previously reported (E. S. R., 26, p. 179; 29, p. 178), were conducted in a small specially constructed chamber, with cats of various ages kept side by side with guinea pigs and dogs. Out of 14 cats only 4 became infected. The tubercular changes produced were in most instances only slight but in others quite extensive. According to this there seems to be a great difference in regard to the receptivity of cats to this disease.

Two cases of spontaneous tuberculosis in the rabbit caused by the avian tubercle bacillus, L. COBBETT (Jour. Compar. Path. and Ther., 26 (1913), No. 1, pp. 33-45, figs. 4).—"As tuberculosis caused by one or the other type of mammalian tubercle bacilli is not confined entirely to mammals, but may occur in the parrot, the raven (Rabinowitsch), and probably also in the canary and sparrow, so tuberculosis caused by the avian tubercle bacillus is not limited to birds, but may sometimes be found in the pig, the mouse, and perhaps in man and the ape also."

In this paper two cases of natural infection of rabbits, which were kept in the same yard with a number of guinea pigs and tubercular fowls, are described. Cultural investigations and the results of autopsies are included.

Subcutaneous tuberculosis in bovines, C. PÉRARD and G. RAMON (Bul. Soc. Cent. Méd. Vét., 90 (1913), No. 8, pp. 167-174).—Under the name "subcutaneous tuberculosis" the authors designate not only the disease caused by hypodermic injections but also the condition which is produced by the process of extension whereby the organisms enter the superficial fibers of the muscles. The lesions in this area were found to differ markedly in their macroscopic aspects from those usually noted in classical tuberculosis. They resemble somewhat the metastases which occur in cancer, and those in sporotrichoses or blastomycoses. The diagnosis on the cadaver is rather difficult.

The findings with some cases of this variety of tuberculosis are given.

Investigations in regard to the specific action of tuberculosis serum by mixing tuberculin and tuberculosis serum, A. SATA (Ztschr. Immunitätsf. u. Expt. Ther., 1, Orig., 17 (1913), No. 1, pp. 84-98, pl. 1).—By simply mixing old tuberculin or powdered tubercle bacilli with tuberculosis serum under certain quantitative and other conditions and at a temperature of 33° C., it is possible to produce a poison in vitro which, with sound guinea pigs, will give the characteristic tuberculin reactions. The reactions so produced are characterized by a rise in temperature, resulting in the classical anaphylactic death.

By keeping the toxin for several days in the incubator, its toxicity is destroyed, and consequently it will not be lethal for guinea pigs and will not yield the typical reactions on injection. In this case there probably occurs the scission of the toxic substance, which is supposed to go on in two phases.

Passive transference of tuberculin sensitiveness by tuberculosis serum, and the valuation of the serum by this method, A. SATA (Ztschr. Immunitätsf. u. Expt. Ther., 1, Orig., 17 (1913), No. 1, pp. 62-75, figs. 5).—It is possible to produce a hypersensitiveness in guinea pigs by treating them with tuberculosis serum. The passive immunity so produced is not only character-

ized by a typical rise in temperature when injecting tuberculin, but it is also possible to produce lethal results by the injection of the tuberculin. This process affords a measure of the activity of the tuberculosis serum.

Investigations in regard to the specific action of tuberculosis serum with anaphylatoxin tests, A. SÄTA (*Ztschr. Immunitätsf. u. Expt. Ther.*, I, Orig., 17 (1913), No. 1, pp. 75-83).—Anaphylatoxin (used in Friedberger's sense) can be prepared from tubercle bacilli either by treatment with complement or by pretreatment with normal horse serum or immune serum. A further cleavage of anaphylatoxin into lower nontoxic products can be made if the conditions of the experiments are modified.

In regard to the value of the urochromogen reaction as an indicator for tuberculin treatment, M. WEISZ (*Wiener Klin. Wchnschr.*, 25 (1912), No. 28, p. 1094; *abs. in Ztschr. Immunitätsf. u. Expt. Ther.*, II, Ref., 6 (1912), No. 2, p. 448).—The detection of urochromogen in urine with Ehrlich's diazo reaction or with Weisz' permanganate reaction leads to the conclusion that the disease is in progress. In this stage treatment with tuberculin is useless and in fact its use is contraindicated.

About the use of the precipitation method for diagnosing contagious abortion, S. SZYMANOWSKI (*Arb. K. Gsndhtsamt.*, 43 (1912), No. 1, pp. 145-154).—It is shown that with a phenol-sodium chlorid extract of abortion bacilli immune sera of high potency can be prepared. The sera from naturally infected animals seem to give variable results, some giving weak reactions and others no reaction at all.

In a series of tests with sera from a number of bovines which were apparently sound, a precipitation was obtained with the phenol-sodium chlorid precipitant; consequently the precipitation test conducted with this reagent can not be relied upon.

Infectious abortion in cattle, and its control by means of vaccination, O. SCHREIBER (*Deut. Tierärztl. Wchnschr.*, 21 (1913), No. 3, pp. 33-35; *abs. in Jour. Compar. Path. and Ther.*, 26 (1913), No. 1, pp. 54, 55).—This is a complete report of the work previously noted (*E. S. R.*, 28, p. 380). Forty-three of 56 fetuses examined came from 19 farms where abortin was administered to the animals, and in most of the fetuses bacteria in addition to the *Bacillus abortus* were noted.

Methylene blue, a remedy for infectious abortion, F. A. RICH (*Vermont Sta. Bul.* 174, pp. 315-323).—This is a preliminary report of investigations by the author extending over a period of 15 years in the course of which various preventive and remedial agents were tested. In its action on *Bacillus abortus* the author found methylene blue (medicinal grade) to be from twenty to fifty times more effective than carbolic acid. It has proved almost uniformly successful, is readily administered, and is apparently free from danger to man or beast.

In laboratory tests of the effect of methylene blue on the abortion bacillus no growth resulted where methylene blue was used at strengths of 1:1,000 for 1 to 3 minutes; 1:2,000 for 1 to 5 minutes; 1:4,000 for 4 to 8 minutes; 1:5,000 for 30 minutes; 1:6,000 for 1 hour; 1:8,000 for 2 hours; and 1:10,000 for 3 hours.

In his experiments the author made use of 4 herds. Of 30 cows in the first herd, all of which reacted to both the agglutination and the complement fixation tests, one-half received $\frac{1}{2}$ oz. of methylene blue daily on grain or silage for a period of 30 days, while to the other half it was administered in gelatin capsules for a period of 6 or 7 days, the dosage being repeated after a period of 4 weeks. In one animal the disease appeared to have progressed too far for favorable issue as abortion took place on the second day of the treatment. At the time of writing 14 of the treated cows had calved at full term and the remaining 15

were still under treatment and observation. In the second herd each of 31 animals reacting to the agglutination test was given $\frac{1}{2}$ oz. of methylene blue on feed daily for 30 consecutive days and all calved normally. In the third herd 23 cows which reacted to the agglutination test received 10 gm. of methylene blue on silage night and morning for 6 consecutive days and after 4 weeks' interval the treatment was repeated, the methylene blue being given in gelatin capsules. At the time of writing none of the 23 animals treated had aborted, and 8 had calved normally at full term. In the fourth herd 9 animals, all but one of which gave positive agglutination tests up to 1 to 50, were given $\frac{1}{2}$ oz. of methylene blue in gelatin capsules once a day for 6 days, followed by an interval of 4 weeks, as in herd No. 3. At the time of writing 3 of the 9 cows had calved at full term and no case of abortion had occurred in the herd since the beginning of the treatment.

Generalized mycosis in the bovine, P. LANGRAND (*Hyg. Viande et Lait*, 7 (1913), No. 9, pp. 425-433, figs. 4; *abs. in Vet. Rec.*, 26 (1913), No. 1319, pp. 246, 247).—The author reports upon a case of this disease in a cow, including post-mortem and microscopic findings.

The keeping quality of antihog cholera serum, S. BAROK (*Állatorvosi Lapok*, 35 (1912), No. 48, pp. 569, 570; *abs. in Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 13, p. 241).—Hutyr's serum was obtained 1 year after manufacture. In the cases where it was used, it had not only protective power but decided curative properties. Pigs having a temperature of 41.6° C., bloody feces, vomiting, and nosebleed were cured by this serum.

A disease (salmonellosis porcina) in pigs, J. LIGNIÈRES (*Rev. Zootec.*, 4 (1913), No. 45, pp. 503-514).—In Argentina there is a disease prevalent among pigs which resembles hog cholera somewhat, and attacks principally the younger animals. It is characterized especially by the production of necrotic lesions in the intestinal mucosa, in the vicinity of the ileocecal valve, and in the large intestines. Caseation is also noted in the mesentery. It is supposed to be caused by an ultramicroscopic organism.

Inoculation and cohabitation tests, with a discussion of the prophylaxis and serum-therapy, are included.

An enzootic among young pigs caused by a variety of the Streptococcus pyogenes, RIEVEL (*Deut. Tierärztl. Wchnschr.*, 21 (1913), No. 12, p. 179; *abs. in Vet. Rec.*, 26 (1913), No. 1318, pp. 230, 231).—Numerous cases of sickness, which appeared among young pigs confined in exposed pens and resulted in a mortality of 50 per cent, were found to be due to a variety of *S. pyogenes*.

Injury to fetlock with purulent infection—autotherapy, J. MACDONALD (*Amer. Vet. Rev.*, 43 (1913), No. 3, p. 300).—A description of a case in a coaching horse from London, which was successfully treated by autotherapy.

Fistulous withers, and synovitis of the coronary joint—autotherapy, R. S. MACKELLER (*Amer. Vet. Rev.*, 43 (1913), No. 3, pp. 300, 301).—A description of cases successfully treated by the method.

Contribution to the knowledge of virus carriers of influenza of the horse, A. M. BERGMAN (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 13 (1913), No. 3-4, pp. 161-174, figs. 4).—The author reports having found an apparently healthy stallion, 21 years old, which transmitted influenza to all of the mares covered during the last $6\frac{1}{2}$ years of his life. The incubation period of the disease in these mares was from 4 to 6 days. No other changes than the catarrh of the mucous membrane of the seminal vesicles of this animal were detected. Three horses injected subcutaneously with the contents of the seminal vesicles became infected. This stallion is said to have always transmitted the typical catarrhal and never the pectoral form. Three horses that were subcutaneously injected with prostate secretion, the contents of the seminal vesicles, and of

the ampulla of the vas deferens, respectively, showed symptoms of influenza within 3 to 5 days thereafter. The fact that no micro-organisms of etiologic importance could be demonstrated therein microscopically or culturally leads the author to conclude that the virus is ultravisible. He considers catarrhal influenza (Rotlaufseuche, influenza erysipelatosa) and pectoral influenza or contagious pleuropneumonia (Brustseuche) to be two independent diseases.

The etiology and therapy of typhoid fever or influenza in the horse (Pferdestaupe), E. BEMELMANS (*Centbl. Bakt. [etc.], 1. Abt., Orig.*, 68 (1913), No. 1, pp. 8-28, fig. 1).—Investigations extending over a period of 5 years lead the author to distinguish between catarrhal influenza or typhoid fever (Pferdestaupe) and contagious pleuro-pneumonia (Brustseuche) of the horse, which he considers to be two independent affections.

He concludes that the influenza (Pferdestaupe) virus is ultravisible, as reported by Basset (*E. S. R.*, 28, p. 184), since the affection can be transmitted by the porcelain filter filtrate from blood obtained from horses naturally or artificially infected. The virus may remain virulent for a long time, even for 3 years, in the seminal vesicles of a healthy stallion which may infect mares at the time of service. Such mares act as a source of infection to other horses in the stable. The infection is not transmitted to any distance by intermediary carriers. The period of incubation in artificially infected animals is from 3 to 5 days. In blood kept at room temperature the virus loses its virulence in 3 months. The course of influenza is benign, save in colts and pregnant mares, and under normal conditions recovery takes place in from 10 to 12 days. The author considers it desirable that horses at remount stations be artificially infected with the influenza virus and that this be done as soon as possible after their arrival at the station.

Influenza among remounts and its treatment with salvarsan, JÄGER (*Ztschr. Veterinärk.*, 25 (1913), No. 7, pp. 289-299; *abs. in Vet. Jour.*, 69 (1913), No. 460, pp. 470, 471).—This paper is based upon studies of a large number of cases of the disease. The treatment with salvarsan consisted in the injection of 3 gm. dissolved in 150 cc. of a 0.9 salt solution into the jugular vein, one dose being sufficient.

The author finds that "salvarsan causes a quick decline of fever and a shortening of the whole fever period, a slow favorable influence on the activity of the heart, a limiting and retarding of the pneumonia, a beneficial effect on the appetite and general condition—loss of weight seldom occurred, a shortening of convalescence, no checking or avoidance of dreaded subsequent effects—tendonitis, roaring, etc., scarcely any arrest or stoppage of the source of infection, and scarcely any shortening of the duration of the illness."

A note upon strangles in the Philippine Islands, W. H. BOYNTON (*Philippine Jour. Sci., Sect. B*, 8 (1913), No. 3, pp. 237-240).—"From the results derived from the cultures and from microscopic examinations of the purulent discharges, it is evident that streptococcic infection exists in horses in the Philippine Islands.

"Since bouillon cultures had no effect on rabbits and guinea pigs when inoculated subcutaneously, and did have decided effect upon a horse, it proves conclusively that the organism isolated was *Streptococcus equi*. No white mice were on hand, so the virulence of the culture could not be tested on them.

"From the information gained through inquiry it is very evident that strangles is a widespread disease among horses in the islands, an interesting fact in view of the reputed rarity of streptococcic infections in man."

Protective substances of fowl cholera immune serum, E. WEIL (*Arch. Hyg.*, 76 (1912), No. 8, pp. 343-400; *abs. in Ztschr. Immunitätsf. u. Expt. Ther.*, II, Ref., 6 (1912), No. 12, p. 911).—The immunizing power of immune serum which

was first brought into contact with killed fowl cholera bacteria was lowered or entirely destroyed when injected into animals which received simultaneously intraperitoneal or subcutaneous injections of the bacteria. If the immunization is made 18 hours before the infection, the weakening effect is not noted. If the animal is infected peritoneally and immunized at the same time, but with a dose selected to kill after 18 to 20 instead of 12 hours, the immunizing power of the serum is not affected.

The rapid cure of polyneuritis gallinarum by intramuscular injection of a substance isolated from rice—note on the pathology of the disease, C. WELLMAN, A. C. EUSTIS, and L. C. SCOTT (*Amer. Jour. Trop. Diseases and Prev. Med.*, 1 (1913), No. 4, pp. 295-299).—The investigations of which the preliminary report is here given were carried on along lines similar to those indicated by Funk (*E. S. R.*, '27, p. 868) and others.

Healthy chickens were fed on diets of polished rice, grits, and sago, and in the interval before the symptoms of polyneuritis should show themselves, intramuscular injections were made of extracts of rice polish prepared by the same method as that used by Funk, save that after concentrating "and neutralizing with NaOH, Ba(OH)₂ was added and the barium soaps together with the precipitated phytin filtered off. Barium was eliminated with carbon dioxide and sulphuric acid, following which came the precipitation with phosphotungstic acid, its decomposition with baryta, and concentration of the filtrate in vacuo at from 50 to 56° C."

The authors feel justified in drawing the following provisional conclusions from the investigations as thus far conducted: "The curative substance acts independently of the liver or alimentary tract, and it is readily absorbed from intramuscular injections. Degeneration of the nerves is confined principally to disturbance in the myelin sheath of the fibers. Neither the sensory nor motor tracts of the cord, medulla, or brain undergo any observable changes. There is a possibility that the cause of convulsions may lie in spinal irritation caused by subdural hematomas due probably to increased permeability of the vessel walls."

RURAL ENGINEERING.

Irrigation branch (*Rev. Rpt. Bihar and Orissa [India], Irrig. Branch, 1911-12*, pp. 11+9+24+28+5+2).—The transactions of the irrigation department of the Government of Bihar and Orissa for the year 1911-12 are given in so far as they relate to works of irrigation and navigation.

Irrigation of Santa Cruz Valley, M. C. HINDERLIDER (*Engin. Rec.*, 68 (1913), Nos. 8, pp. 200, 201, figs. 3; 9, pp. 242, 243, figs. 8).—This article describes a system for recovering underground water in Arizona by means of deep wells and pumping stations. Since the water-bearing formation underlying the impervious subformation beneath the valley is comparatively shallow it was necessary to develop unusual and novel features, the most important of which is a recovery system consisting of 19 wells drilled to depths ranging from 45 to 150 ft. in a straight line across the narrow part of the valley to intercept the underground waters, together with the necessary pumping equipment. These wells are connected by means of a gravity conduit of reinforced concrete 4,740 ft. in length, located and built from 5 to 12 ft. below the water plane of the valley.

The distributing system consists of a reinforced concrete pipe line 48 in. in diameter and 1,500 ft. in length, forming the outlet from the recovery system; a 48 in. concrete siphon under the Santa Cruz River; about 7 miles of earth canal, some of which is lined with concrete; and 21 miles of laterals.

Pressure pipes for the conveyance of water and for inverted siphons, B. A. ETCHEVERRY (*Jour. Electricity*, 30 (1913), Nos. 21, pp. 474, 475, figs. 2; 22,

pp. 494, 495, figs. 4).—The mathematical analyses given of the design of sheet steel and wooden stave pressure pipes include the derivation of formulas for thickness of steel pipe, size and spacing of bands, and size of staves for wooden stave pipe. Wooden stave pipe are claimed to be cheaper than steel pipe, not subject to corrosion, to have a greater carrying capacity than a riveted steel pipe of the same diameter, if kept saturated to be of probably greater durability, and to be unaffected by heat or cold. Its disadvantages are that it must be kept saturated continually and is liable to destruction by fire.

Methods of constructing reinforced concrete pressure pipe are described.

The economics of pipe line diameters (*Engin. and Contract.*, 40 (1913), No. 9, pp. 237-240, figs. 8).—In a paper taken from the proceedings of the Pacific Northwest Society of Engineers C. W. Harris analyzes, mathematically and graphically, methods for determining economical pipe line construction for power development, water supply, and irrigation, considering first the smallest pipe which will deliver a given amount of power; second, the smallest allowable diameter without exceeding allowable velocities; and third, economical diameter considering the value of the water right.

The following points are summarized as solutions to these considerations:

When the water consumed has no value it is allowable to use the smallest possible pipe line for power which, with a friction loss of one-third of the total head, will deliver a quantity of water sufficient to produce the required power with the other two-thirds of the total head.

If a pipe line is subjected to a varying head throughout its length, but the cost for any particular diameter remains constant for those various heads, the diameter should also remain constant throughout; but if the cost of the pipe is different for the different heads the diameter should be smaller for the larger head. The correct diameter under any particular head is that which will make $n/5$ of the cost of the pipe for a given length equal to the capitalized value of the power consumed by friction in that same length, n being 2 for steel pipe and 1.5 for wooden stave pipe, and for any pipe taking the index of d in the expression. $\text{Cost} = kd^n$, in which k is a constant depending on the cost of steel per pound, interest, depreciation, etc. With this diameter determined under one head the diameter of the same pipe under any other head should vary inversely as the seventh root of the head if the pipe is a high-pressure steel pipe, or as the ninth root of the head if the pipe is wood stave. If the quantity to be delivered is fixed, and the available friction loss is also fixed, as is the case with a pipe line connecting two reservoirs of fixed elevations, the diameter of the pipe line should vary throughout the length thereof according to the laws expressed above, the head to which the pipe is subjected being the static head for which the pipe is designed.

Light-iron irrigation flume (*Engin. Rec.*, 68 (1913), No. 6, p. 153, figs. 3).—This article notes the use of light semicircular ingot-iron smooth flumes installed on a light wooden substructure on the Pala Indian Reservation in California. The sections vary from 12.5 to 15 in. in radius. After completion carrying-capacity tests gave a value for the coefficient of roughness in Kutter's formula of 0.010 for a 30 in. diameter flume. The total cost, including substructure, was \$2.61 per lineal foot.

Heavy oil as fuel for internal combustion engines, I. C. ALLEN (*U. S. Dept. Int., Bur. Mines Tech. Paper* 37, pp. 36; *Sci. Amer. Sup.*, 76 (1913), No. 1977, pp. 326, 327; *Indus. Engin. and Engin. Digest*, 13 (1913), No. 9, pp. 392-395).—A review of heavy fuel oils available for use in internal combustion engines is followed by a discussion of heavy oil engines, including the Diesel and semi-Diesel types and a summary of the requirements of heavy oil engines

relating to ease of starting, steady and efficient operation at all loads, complete combustion, simplicity in regulation, and low first cost.

The fuel economy of heavy oil engines is briefly summarized as follows: Approximately 0.4 lb. of oil is consumed per horsepower hour, whereas for a steam engine of the best triple expansion type from 1.1 to 1.8 lbs. of fuel are necessary, thus giving an economy ratio of approximately 1:3 in favor of the oil engine.

Fuels that may be successfully used in heavy oil engines are enumerated as follows: Petroleum products, "Steinkohle" oil products, bituminous oils, lignite products, turf oils, shale oils, vegetable oils, animal oils, alcohols, and wood oils.

Specifications for fuels and lubricants for heavy oil engines are summarized as follows: The oil should be mobile at 0° C. Sluggish oils should be heated before being introduced into the engine, and oil should contain not more than 0.4 per cent of material insoluble in xylene. The residue on coking should not be greater than 3 per cent and there should not be more than a trace of free carbon in the oil. At least 80 per cent of the oil should distill over at 350° and heavy oils and residues should properly be distilled before using. The flash point should be between 60 and 100°. A heavy oil containing no material having a low flash point should be enlivened by the addition of about 2 per cent of a "gas oil," the flash point being 60 to 100° or less. The specific gravity should not be greater than 0.920. The heating value should be not less than 9,000 calories, the hydrogen content not less than 10 per cent, and the sulphur content not more than 0.75 per cent. The oil should contain no free ammonia, alkali, or mineral acids, not more than 0.05 per cent of noncombustible mineral matter, and not more than 1 per cent of water. The resin content should be low, the paraffin content not more than 15 per cent, the creosote content not more than 12 per cent, and the asphaltum content sufficiently low to allow the fluid to flow. Fine atomization is essential.

The viscosity of lubricants should be between 9 and 10° Engler at 50°. The lubricants should be liquid at -5° and should not freeze solid above -10°. The flash point should be between 220 to 240° in a Pensky-Martens closed tester. The lubricant should lose not more than 10 per cent by carbonization when agitated with concentrated sulphuric acid, should dissolve completely and clearly in benzene, and should be free from acids and alkali. Animal and vegetable oils should not be used.

It is stated in conclusion that the heavy oil engine can not yet be considered as fully developed, but the fact that petroleum containing as high as 20 per cent asphaltum as well as oils from tars have been successfully used is most encouraging for its future.

Naphthalin for gas engines (*Gas Engine*, 15 (1913), No. 8, pp. 455, 456).—Attention is called to the use of naphthalin in internal-combustion engines. It is stated that this material consists of approximately 94 per cent carbon and 6 per cent hydrogen, melts at 174° F., boils at 424°, and has a specific gravity of 1.15.

Carbureters adapted to the use of naphthalin are (1) those which melt and vaporize the naphthalin itself, and (2) those which vaporize a solution of the substance in some volatile liquid. Ether is the best solvent, but its cost is prohibitive. Benzine dissolves from 30 to 40 per cent at atmospheric temperature, and alcohol may be also used, although in every case a heated carbureter is necessary.

The advantages claimed for naphthalin are as follows: It is not readily inflammable; for a given amount of work it occupies smaller space than gasoline;

it solidifies in cold air, thus minimizing the possibility of leakage; and it has a definite composition.

In French tests of this fuel a 4-cylinder motor with a 135-mm. bore and a 145-mm. stroke developed 35 b. h. p. at 888 r. p. m. at a cost per brake horsepower hour of about $\frac{1}{3}$ ct., and a 2-cylinder motor with an 88-mm. bore and 140-mm. stroke developed 8 h. p. at 1,100 r. p. m. at a cost per brake horsepower hour of about $\frac{1}{3}$ ct.

The naphthalin motor, O. H. HAENSSGEN (*Gas Engine*, 15 (1913), No. 10, pp. 537-542, figs. 6).—The mechanical details and operation of several makes of both 2- and 4-cycle motors operating on naphthalin fuel are described. All of these require a light liquid fuel for starting and stopping and for generating heat, either in the exhaust or in the cooling water, sufficient to melt the naphthalin.

Connecting electric motors for direct drive, C. B. MILLS (*Brick and Clay Rec.*, 43 (1913), No. 5, pp. 468-470, figs. 2).—This article takes up the purely mechanical considerations in the application of electric motors to machinery and deals with the advantages and disadvantages of several styles of connection between motor and machine, including belt, rope, toothed chain, gear-and-pinion connections, and cushion and flange couplings for direct connections.

The transmitting powers of belts and ropes at various speeds are graphically represented and designs of connections are mathematically analyzed. It is stated that since the armature of the average type and size of motor is composed of a great number of parts of little mechanical strength it is important to choose a method of connection which will tend to absorb or minimize shock and vibration.

Installation and care of storage batteries, H. M. NICHOLS (*Sci. Amer. Sup.*, 76 (1913), No. 1965, pp. 130, 131).—This article considers the layout and installation of storage batteries and takes up in detail their operation and maintenance, including the location and correction of the most frequent troubles. These are enumerated as short-circuiting, sulphating, flaking, disintegration, and warping of the plates. It is stated that each cell in a battery should be carefully inspected and tested, when fully charged, once a week, and that a record should be kept of weekly inspections of each cell for comparative purposes.

The Winnipeg tractor trials, L. W. ELLIS (*Sci. Amer.*, 119 (1913), No. 10, pp. 201-204).—These trials, the sixth of their kind, brought out the fact that both large and small farmers are now more keenly interested in the medium to small general-purpose tractor.

The tests consisted of (1) a 2-hour economy brake test; (2) a $\frac{1}{2}$ -hour maximum brake test; (3) a 3 to 5-hour economy, efficiency, and capacity plowing test; and (4) a careful comparison of design and construction. Out of 500 points the first was allotted 150, the second 50, the third 200, and the fourth 100. The highest net score attained was 437.3 points. The brake showings were quite uniformly good, and little distinction was made between the tractors on design and construction. A new feature was the use of a vibration detector. The most severe criticisms on design and construction were on lubricating systems and insufficient protection of working parts from mud and dust.

The plowing tests were held on ground which had been plowed before and which had a 2 ft. growth of weeds. The average cost of plowing per acre for steam engines was 46.3 cts., for kerosene 50.9 cts., and for gasoline 62.1 cts. The 5- and 6-plow tractors plowed about $1\frac{1}{2}$ acres per hour, the 4-plow rigs about 1 acre, 8-plow rigs behind large gas tractors $2\frac{1}{4}$ acres, and 10-plow rigs $2\frac{3}{4}$ to 3 acres. Plow for plow the steam engines showed more capacity, largely due to higher geared speed of travel.

Revolution counters on both engines and brakes showed a variation in belt slippage of from 0.3 to 1.5 per cent.

Gasoline tractors averaged close to 4 times as many horsepower hours per unit of fuel as steam tractors, while kerosene tractors secured about 3 times the fuel efficiency of the steam tractors. Excluding labor costs, however, the steam tractors developed brake horsepower at a rough average of 20 per cent less than the kerosene engines and every steamer defeated every gasoline tractor on fuel cost per unit of brake power. This is considered a powerful factor in retaining the moderate-sized steam tractor of from 50 to 75 b. h. p. wherever threshing is of greater importance than plowing.

Tables of data are appended showing the most important points of comparison, the total scores, and the relative standings.

Mechanical cultivation in Germany, F. BORNEMANN and B. DONÁTH (*Die Motorkultur in Deutschland. Berlin, 1913, pp. VIII+230, figs. 121*).—This book, based on the results of extended experiments, deals, in connection with mechanical cultivation, with economy in the purchase of motor cultivating machinery in Germany, and calls attention to the special points to be considered in the judgment and choice of the various types for various classes of work. A chapter on historical development is followed by a discussion of the relation of mechanical cultivation to political and actual working economy.

From a comparison of motor plows and scarifiers with steam tractor plows it is concluded that the first two are best adapted to shallow surface cultivation while the last is adapted to deep plowing. A comparison of mechanical and electrical cultivation indicates that the first is on the whole the cheaper. An exhaustive discussion of the mechanical details of motor cultivating machinery calls particular attention to those points to be criticized in selecting or buying machinery for various works.

Descriptions of several single systems include both disk and moldboard plows, among which are (1) a plow and motor built together in a single frame, (2) one in which they are in separate frames and connected by chains or other coupling, (3) rope and windlass-drawn gang plows, (4) rotating disk plows, and (5) motor scarifiers.

In conclusion it is stated that so far no motor cultivators have been put upon the market which are adapted to all conditions, and that their profitable use is a matter depending on the good judgment of the owner.

Various devices for drying the autumn forage harvest, RAHM (*Illus. Landw. Ztg., 32 (1912), No. 80, pp. 741, 742, figs. 17*).—Several devices are illustrated and described which are used in Germany, Sweden, and the hill lands of other European countries. Among these are wooden rail frames, post and wire frames, and posts fitted with teeth.

RURAL ECONOMICS.

Cooperation and nationality, G. W. RUSSELL (*Dublin, 1912, pp. 104*).—The various rural activities as they bear upon the social and economic life of a nation and its rural population are discussed in this volume in chapters with the following headings: The problem of rural life, past and present conditions, need for an agricultural revolution, the rise of agricultural cooperation, building up a new social order, town and country, organized communities and political life, the creation of citizens, women on the land, union of men and women workers, farmers and the State, ideals of the new rural society, and life finding its level.

The legal status of farmers' cooperative associations (*Internat. Inst. Agr. [Rome], Mo. Bul. Econ. and Soc. Intel., 4 (1913), No. 10, pp. 18-25*).—This

article enumerates and describes briefly some of the difficulties experienced in organizing farmers' cooperative associations under existing laws in the United States and calls attention to special provisions made for such associations in the States of California, Wisconsin, Massachusetts, Nebraska, and Texas.

Agrarian reforms and the evolution of the rural classes in Russia, P. CHASLES (*Rev. Écon. Internat.*, 10 (1913), IV, No. 1, pp. 55-85).—This article discusses and illustrates the significance of various agricultural questions in Russia, as, for example, the work of the rural bank and its relation to emigration in Russian Asia, the growth of rural estates, transition from agricultural collectivism to individual property, the redistribution of land and the breaking up of the village community, the results of agricultural organization, and the progress of rural agriculture during the last few years.

United effort for farm betterment and rural progress (Farm and Home [Mass.], 34 (1913), No. 731, pp. 639, 643, figs. 4).—This article outlines the plan and describes the efforts of the Hampden County Improvement League of Massachusetts to consolidate the various agencies in the county for economic social progress in the small villages and rural districts. In the 6 months since the league was formally organized, pledges of financial support aggregating over \$10,000 have been obtained and a corps of 3 advisers appointed. More than 300 farmers have been visited and advised as to methods, fertilizers, land drainage, seeds and seeding, testing milk, judging and selecting dairy animals, etc., and 442 farmers about general orcharding. The advisers have also aided in purchasing lime and fertilizers, introducing alfalfa and other crops, and forming local organizations. In one of these, the fruit growers' association in Granville, the members have received from \$3.75 to \$4 per barrel for apples this year while nonmembers received from \$2.75 to \$3. Other illustrations of the work are given.

Agricultural credit banks of the world (Banking Law Jour. Yearbook, 1913, pp. 40, figs. 12).—A brief but comprehensive discussion of the actual operations of foreign mortgage loan systems and the cooperative agricultural credit system is here presented. Accounts of typical mortgage loan banks are given which serve to illustrate the relation of agriculture to the credit facilities in the various countries.

Cooperative credit associations in Canada, T. K. DOHERTY (Internat. Inst. Agr. [Rome], Mo. Bul. Econ. and Soc. Intel., 4 (1913), No. 6, pp. 16-22).—This article presents a brief summary of the conditions leading to the establishment of cooperative credit banks or associations in Canada, describes their system of administration, and submits a statement as to the amount of business done by a number of them.

There were 98 such associations in the Province of Quebec in 1912, besides several in Ontario. The capital is raised by selling shares and by utilizing the profits. A member's liability does not exceed the limited amount of stock he can hold, and he has but one vote. Loans for purposes which conform with the aims of the association are granted on the note of the borrowing shareholder alone or may be guaranteed by other solvent members. The running expenses of these associations are found to be light, the only official being the business manager, who is paid according to the time he devotes to the work. Further details are presented by notes and tables.

The work of the special agricultural credit institutes in 1912 (Internat. Inst. Agr. [Rome], Mo. Bul. Econ. and Soc. Intel., 4 (1913), No. 10, pp. 55-63).—The work of the special agricultural credit institutes in 11 Provinces of southern Italy and Sicily which under the law of 1911 came under the management of the savings department of the Bank of Naples and the agricultural credit department of the Bank of Sicily, respectively, is briefly summarized.

Tables are given showing amount of loans granted by each institution for various farm operations, together with the security therefor. The operations concluded by the Bank of Naples during the year amounted to 9,353,833 francs, the loans on legal preference mortgages representing 63.42 per cent, those not so secured 30.04 per cent, and those secured on the deposit of agricultural produce 6.49 per cent. Of the total loans 11,736, amounting to 4,327,975 francs, were granted to landholders working their farms, and 6,142, amounting to 2,753,899 francs, to tenant farmers. The agricultural credit department of the Bank of Sicily granted loans during the year to 38,155 intermediary organizations, amounting to 12,025,635 francs.

Tables are given showing the classification and amount of loans according to the different crops and the position of the borrower.

Government valuation of land (*New Zeal. Off. Yearbook 1912, pp. 602-622*).—The various features of the Valuation of Land Act, passed by the New Zealand Government in 1896 and amended in 1908, are described here in detail. The valuation rolls, showing the selling value of all land in the Dominion, are used for taxation purposes as a basis on which loans may be granted by the New Zealand State-guaranteed Advances Office and for the guidance of the Land Purchase Board when acquiring land under the Land for Settlements Act, and by others who may desire to ascertain the selling value of any piece of land for investment, mortgage, etc.

Tables are given showing the capital value of the land with improvements, together with improved values by counties and boroughs, 1878-1912.

Studies of primary cotton market conditions in Oklahoma, W. A. SHERMAN, F. TAYLOR, and C. J. BRAND (*U. S. Dept. Agr. Bul. 36, pp. 36*).—This bulletin presents the results of a market survey made in 103 towns in Oklahoma in which were secured samples of over 3,200 bales of cotton with records of date and place of sale and price paid to the grower. Comparisons are made as to the classification of the grades and the difference in prices paid in some markets on the same day for bales of identical quality. Such variation in prices is shown to have amounted to as much as \$12.50 per bale for low middling cotton. "The greatest losses to the farmers under the present system of marketing appear to lie in their failure to secure the premium for their high grades which these grades finally bring."

Notes and tables are given showing in detail the results of the survey.

An example of successful farm management in southern New York, M. C. BURRETT and J. H. BARRON (*U. S. Dept. Agr. Bul. 32, pp. 24, figs. 5*).—This bulletin describes at length the methods employed by a farmer without previous experience in converting a farm not paying expenses into a profitable enterprise. It gives the method of solving some of the important problems in farm management by improving the dairy, diversifying crops, the use of rotations, and the intelligent use of horse and man labor. Tables are given showing the cost, yield, and income of the various farm operations.

What I know about farming, E. J. GRINNELL (*Minneapolis, Minn., 1913, pp. 328, pls. 37*).—In this book the author discusses, largely from his own experience, various phases of farming and farm life, such as soil fertility and fertilization; the business farmer and his qualification; farm buildings; pastures and meadows; the vegetable garden; corn and small grains; small fruit raising; the orchard; trees and farm forestry; the flower garden; bees; poultry; stock breeding; dairying; frosts and sprays; the woman on the farm; early-day farming in the East; and miscellaneous other subjects.

AGRICULTURAL EDUCATION.

Agricultural and forestry instruction in Italy, A. KASTNER (*Land u. Forstw. Unterrichts Ztg.*, 27 (1913), No. 1-2, pp. 108-128).—An account is given of the present status of agricultural and forestry instruction in Italy administered by (1) agricultural high schools at Milan, Perugia and Portici; (2) royal technical agricultural schools, including the viticultural schools at Alba, Avellino, Cagliari, Catania, and Conegliano; (3) royal agricultural special schools, viz, the Royal Pomological and Horticultural School at Florence, and the Royal Veterinary and Dairy School at Reggio-Emilio; (4) royal practical agricultural schools of which there are 28; (5) 3 private agricultural institutions including the Agricultural Colonial Institute at Florence, and 2 practical schools; (6) agricultural and housekeeping schools for girls; (7) agricultural experimental institutions; (8) itinerant agricultural instruction; (9) traveling agricultural libraries; and (10) the Royal School of Forestry at Vallombrosa, and the Royal School for the Training of Forest Guards at Cittaducale.

[**Agricultural and forestry instruction in Austria and Italy**] (*Land u. Forstw. Unterrichts Ztg.*, 27 (1913), No. 1-2, pp. V+168+LXIX).—In addition to several articles abstracted elsewhere in this issue, this report includes (1) statistics of agricultural education institutions in Austria in 1912-13, showing an addition during the year of 1 agricultural intermediate school, 5 agricultural winter schools, 2 housekeeping schools, an agricultural winter and vegetable culture school, and a school for fruit growing, and the discontinuance of a farm and hop culture school, 2 agricultural winter schools, a housekeeping school, and a brewing school; (2) a review of agricultural literature, and (3) a list of the agricultural and forestry education institutions in Austria with their faculties.

The celebration of the anniversary of the Imperial Royal High School of Agriculture of Vienna (*Land u. Forstw. Unterrichts Ztg.*, 27 (1913), No. 1-2, pp. 1-11).—This is an account of the celebration on May 8 and 9, 1913, of the one-hundredth anniversary of the establishment of the institute for forestry instruction, known later as the forest academy at Mariabrunn, which in 1875 was transferred to the High School of Agriculture of Vienna as the first institute for higher instruction in forestry; also of the fortieth anniversary of the establishment of the High School of Agriculture of Vienna, concerning which a description of its most important periods of development is given.

Report of the department of agriculture of Norway, 1912 (*Aarsber. Offentl. Foranst. Landbr. Fremme*, 1912, III, *Statsforanst.*, pp. LXXXV+35+594).—This report gives a comprehensive survey of the work of the various government agencies established for the advancement of Norwegian agriculture and its various branches. The annual reports of the state agricultural experiment stations, seed control stations, milk control stations, and cow-testing associations are included.

World's dairy schools, trans. by J. H. MONRAD (*N. Y. Produce Rev. and Amer. Cream.*, 36 (1913), Nos. 6, pp. 258, 259; 7, pp. 302, 304; 8, p. 348; 10, p. 430; 11, p. 472).—This condensation of a lecture delivered by Dairy Counselor G. Ellbrecht at the Dalum Dairy School in Denmark gives an account of the facilities for dairy instruction in Norway, Sweden, Finland, Prussia, Holland, Belgium, and Switzerland.

Practical School of Aviculture (*Rev. Vet. e Zootech.*, 3 (1913), No. 4, pp. 257-261).—The objects and methods of instruction of the Practical School of Aviculture of Acurra in the Federal District of Rio de Janeiro are set forth. The school has an extensive area of land with equipment for an essentially practical instruction. Its object is to train students to direct poultry farms or enterprises, and to become poultry specialists. The students assist in the work

of the farm and each in turn has charge of the various operations in poultry keeping. A 3 months' course is offered, beginning each quarter.

Vocational education, R. O. SMALL (*Amer. School Bd. Jour.*, 47 (1913), No. 4, pp. 12, 13, 55, 56).—According to this article vocational agricultural departments were in operation in 1912 at 5 Massachusetts high schools. Two county high schools and 4 new departments in high schools have since been established. The scheme of agricultural work devised provides productive home-farm operations carried on for profit by the pupils at the same time they are studying the agricultural science bearing upon these operations. During the year 11 different types of farm projects were selected, ranging from a small garden to a dairy in which 12 Jersey cows were handled and money transactions to the extent of \$1.200 engaged in. See also a previous note (E. S. R. 28, p. 106).

The importance, extent, and execution of student practice at agricultural schools (*Land u. Forstw. Unterrichts Ztg.*, 27 (1913), No. 1-2, pp. 18-33).—This symposium of practicums in agricultural schools discusses their use in agricultural intermediate schools (Mittelschulen) by Fritz Schneider; in farm schools by Alois Gross, and in agricultural winter schools by H. Maresch.

Efforts to reform the system of gardening instruction, K. SCHECHNER (*Land u. Forstw. Unterrichts Ztg.*, 27 (1913), No. 1-2, pp. 34-41).—The new management of the Imperial Royal Horticultural Society of Vienna is endeavoring to bring about a reform in the system of gardening instruction in Austria, and as a first step is establishing horticultural apprentice schools, 4 of which are now in operation with good attendance. The principal object of these schools is to extend the technical knowledge and general culture, and to give some commercial training. The instruction is given for 2 years during the 6 winter months, 9 hours a week in 3 periods from 6 to 8 p. m., and on Sundays from 9 to 12 a. m.

There is also a 2-year course in the schools for gardeners' assistants, admission to which requires the completion of the full course of the apprentice schools. Both schools offer practical summer courses in the first year. The first Austrian horticultural week was held from December 9 to 14, 1912, in Vienna, to give experienced gardeners opportunity to learn of the results of recent investigations and experience. Suggestions are also given for the instruction of persons desiring to learn gardening who can not attend school. For the training of horticulturists higher horticultural schools are provided.

Proposals to bring about uniformity in the methods of instruction in the lower agricultural schools with special reference to schools for wine growers, F. JACHIMOWICZ (*Land u. Forstw. Unterrichts Ztg.*, 27 (1913), No. 1-2, pp. 42-54).—The author suggests and discusses as the most feasible and practical school for the majority of farmers a 3-semester school with a small farm and offering temporary spring and summer courses. The 2 winter semesters should each include 30 hours a week of theoretical instruction, and the summer semester should be devoted almost exclusively to practical work.

Farmers' institutes in Kansas, E. C. JOHNSON (*Agr. Ed. [Kans. Agr. Col.]*, 5 (1913), No. 22, pp. 40).—This pamphlet describes briefly the purpose, character, organization, and methods of work of the farmers' institutes in Kansas, and is intended primarily as a handbook for the institute officers.

Suggestive topics for institute meetings are given on soil fertility, soil tillage, the summer fallow, crops, seed and seed selection, crop rotation, weeds, plant diseases, insects, silos and silage, dairying, beef production, farm animals, the orchard and the garden, roads, marketing, cooperation, organizations, tenant farming and labor, farm management, the home, and sociology.

A catechism of agriculture, T. C. ATKESON (*New York and London, 1913, pp. XII+96, figs. 34*).—This work is a revision of that previously noted (E. S.

R., 21, p. 91), considerably enlarged to make a fairly comprehensive treatment of the general field of elementary agriculture. Sections on farm crop management, dairy management, and farm management, have been added, and the work is illustrated for the first time.

A course in agriculture for the high schools of Michigan, W. H. FRENCH (*Mich. Agr. Col., Dept. Agr. Ed. Bul. 11, 1913, pp. 73*).—This course is outlined in detail, together with suggestions and syllabi on the several subjects to be taught. Lists of agricultural reference books, Michigan Station bulletins, sample score cards, and an outline of work in nature study and elementary agriculture, with suggested exercises and experiments that should be undertaken with pupils in the sixth and seventh grades by the high school teacher of agriculture in cooperation with the grade teachers are appended.

The principles of agriculture through the school and the home garden, C. A. STEBBINS (*New York, 1913, pp. XXVIII+380, figs. 199*).—This text has been planned for use in the upper four grades. The features of the book are the "problem questions" and "home studies," information as to profitable marketing, instructions concerning the forming of agricultural clubs, and data on the plan and purposes of the Boys' and Girls' Junior Garden Club.

The method of the book is far removed from merely dogmatic instruction, the pupils being challenged to test and reason. The apparatus required is limited and inexpensive. The language is direct and very evidently has the children in mind.

Practicums for pupils in the chemical laboratory of agricultural intermediate schools, A. KWISDA (*Land u. Forstw. Unterrichts Ztg., 27 (1913), No. 1-2, pp. 12-17*).—The author discusses the object and character of chemical laboratory practicums for pupils in intermediate agricultural schools and outlines such work for a 3-year course.

An old and well-known child's plaything as an expedient in forestry instruction (*Centbl. Gesam. Forstw., 39 (1913), No. 7, pp. 327-332*).—Detailed directions are given for making a miniature model forest for use in forestry instruction.

The story of our trees, MARGARET M. GREGSON (*Cambridge: University Press, 1912, pp. XII+160, figs. 74*).—This book is arranged in 24 lessons, each complete with its own practical work. The lessons are fitted into the natural cycle of seasons, and are also adapted to the school year. A list of reference books and information concerning diagrams and lantern slides, material, and revision questions are appended.

Common trees: How to know them by their leaves, V. M. HILLYER (*Baltimore, Md.: Calvert School [1913], pp. 30, figs. 37*).—This manual is arranged with a descriptive text of each tree family and its members, together with their leaf silhouettes.

The planting of home grounds, V. H. DAVIS (*Agr. Col. Ext. Bul. [Ohio State Univ.], 8 (1913), No. 9, pp. 16, figs. 25*).—The author discusses the extent of grounds, lawns, style, fences, trees, shrubs, and flowers, and points out a number of common errors in treatment. A list of trees, shrubs, etc., that are desirable for Ohio and other States of similar climate is included.

Wisconsin Arbor and Bird Day annual, 1913 (*Madison, Wis.: State Supt. Pub. Instr., 1913, pp. 109, pls. 5, figs. 27*).—The governor's proclamation of May 2, 1913, as Arbor Day is followed by material on forestry, bird life, wild animal life, fire prevention, and good roads, with suggestions on how considerable of this material may be used throughout the year in connection with the regular school branches.

Illinois Arbor and Bird days, F. G. BLAIR (*Ill. Dept. Pub. Instr. Circ. 68, 1913, pp. 71, figs. 54*).—A collection of nature lessons on trees and birds, to-

gether with nature poems, some of which were written by eighth and second-grade pupils.

Arbor Day program, April 25, 1913 (*Boise, Idaho: Dept. Ed., 1913, pp. 13*).—This pamphlet contains the governor's Arbor Day proclamation, suggestions for carrying out the day's program, and hints on tree planting.

Farm arithmetic, C. W. BURKETT and K. D. SWARTZEL (*New York and London, 1913, pp. XIII+280, pl. 1, figs. 122*).—This farm arithmetic is designed for use in the last 2 or 3 years of the elementary school. The problems presented deal with plant and animal feeding, dairy products, the soil, field crops, fruits and vegetables, farm mechanics, silos, forestry, farm accounts, etc. Answers are given to all the problems.

List of references on rural life and culture (*Washington: U. S. Bur. Ed., 1913, pp. 5*).—An annotated bibliography with a list of the periodicals indexed in its preparation.

MISCELLANEOUS.

Twenty-fifth Annual Report of Colorado Station, 1912 (*Colorado Sta. Rpt. 1912, pp. 51*).—This contains the organization list, a financial statement for the fiscal year ended June 30, 1912, a report of the director on the work and publications of the station, and departmental and other reports.

Twenty-fifth Annual Report of Massachusetts Station, 1912 (*Massachusetts Sta. Rpt. 1912, pts. 1, pp. 240, pls. 12; 2, pp. 97, pls. 4*).—Part 1 of this report contains the organization list, a list of publications during 1912, a financial statement for the fiscal year ended June 30, 1912, a report of the acting director, departmental reports, and numerous special papers. The experimental work recorded is for the most part abstracted elsewhere in this issue.

Part 2, which is the portion designed for general distribution, consists of papers of a popular nature, abstracted elsewhere in this issue and based on the results of observations and experiments of the station, and of a brief summary by the acting director of the more important conclusions from these articles.

Monthly bulletin of the Western Washington Substation, September, 1913 (*Washington Sta., West. Wash. Sta., Mo. Bul., 1 (1913), No. 1, pp. 16, figs. 4*).—This series has been begun to give information relative to agricultural practice under western Washington conditions. The initial number includes brief articles on the following subjects: Farm Management—Green Forage—Fall Seeding, by H. L. Blanchard; Selection of Potato Seed, and A Cover Crop for the Orchard, by J. L. Stahl; Trap Nests and Their Use, by V. R. McBride; Developing Early Maturing Corn, by B. Stookey; Fair Exhibits of Horticultural and Agricultural Products, by J. L. Stahl and B. Stookey; and Identification of Plant Diseases by Station, Directions for Making Bordeaux Mixture, Black Leg of Potato, and Harvesting and Storing Potatoes with Reference to Disease, by H. L. Rees.

Organization of the Department of Agriculture, 1913 (*U. S. Dept. Agr., Organ. Dept. Agr., 1913, pp. 31*).—This publication describes briefly the work of the various branches of the Department and enumerates the officials responsible therefor.

Organization and conduct of a market service in the Department of Agriculture discussed at a conference held at the Department on April 29, 1913 (*U. S. Dept. Agr., Organ. and Conduct Market Serv. in Dept. Agr., Apr. 29, 1913, pp. 15*).—A summary is given of the proceedings at this conference, including an address by G. H. Powell on The California Citrus Industry, Its Organization and Operation (pp. 2-6), and abstracts of other addresses.

List of free and available publications of the United States Department of Agriculture of interest to farm women (*U. S. Dept. Agr., List Free Pubs. of Interest to Farm Women, 1913, pp. 11*).—About 300 publications, classified by subjects, are listed.

NOTES.

Kansas College and Station.—Work has been begun on the new hog cholera plant to consist of a two-story brick building 60 by 40 feet for laboratories, and an office, a crematory for refuse, and a set of cement hog pens. The cost of the plant will be about \$10,000.

Charles H. Taylor has been appointed in charge of animal husbandry work in the extension division. John W. Calvin, assistant in animal nutrition, has been appointed assistant professor of agricultural chemistry and assistant chemist in the Nebraska University and Station beginning February 1. V. V. Detwiler has been appointed assistant in industrial journalism.

South Dakota College.—Press reports announce that President R. L. Slagle has been appointed president of the University of South Dakota beginning February 1. Dr. O. E. White, formerly instructor in botany and subsequently an assistant and graduate student at the Bussey Institution, has accepted an appointment as plant breeder in the Brooklyn Botanic Garden.

American Association for the Advancement of Science.—At the sixty-fifth meeting of this association, held at Atlanta December 29, 1913 to January 3, 1914, former Dean Bailey of Cornell University was chosen vice-president of Section M, the new section on agriculture. The Society of American Foresters was accepted as an affiliated society. The next meeting of the association will be held in Philadelphia.

Massachusetts Federation for Rural Progress.—This organization was formed at a meeting held at the Massachusetts Agricultural College October 21, 1913, under the auspices of the college, the State Board of Education, the State Grange, and the Western Massachusetts Chamber of Commerce. About 15 organizations participated in the meeting. The constitution, as adopted, provides for a council, an executive committee, and three commissions dealing respectively with farm improvement, marketing and exchange, and community life. President Butterfield of the college was chosen president, Dr. David Snedden, state commissioner of education, vice-president, and E. L. Morgan, community field agent of the college, secretary-treasurer.

Third Congress of Tropical Agriculture.—This congress will be held in London, June 23-30, under the presidency of Prof. Wyndham Dunstan, director of the Imperial Institute. Among the topics to be considered are technical research in tropical agriculture, scientific problems in rubber production, methods of developing cotton cultivation in new countries, problems of fiber production, agriculture in arid countries, and hygiene and preventive medicine in their relation to tropical agriculture. Papers on these subjects may be submitted to, and further information obtained from, the organizing secretaries of the congress, Dr. T. A. Henry and H. Brown, Imperial Institute, London, S. W.

Fifth International Congress of Rice Culture.—This congress is to be held at Valencia, Spain, during the second week in May. It will be divided into sections dealing with the breeding, manuring, culture, and harvesting of rice, rice diseases, commerce in rice, and cooperative methods in rice production and market-

ing. Papers may be submitted in any language, but unless in French, Italian, or Spanish should be accompanied by a summary in Spanish. Additional information may be obtained from the Royal Commissioner of Public Works at Valencia, who will serve as president of the congress.

Agricultural Appropriations in New York State.—Among the special appropriations granted by the New York legislature in 1913 were the following: (1) For the establishment of a state school of agriculture and domestic science at Delhi, \$50,000, (2) for the purchase of lands and erection and equipment of buildings for the New York State School of Agriculture on Long Island, \$190,000, (3) for the maintenance and improvement of buildings of the Schcharie State School of Agriculture at Cobleskill, \$22,800, and (4) for the establishment of a course in practical agriculture at the Plattsburg State Normal School, \$3,500.

The *Rural New Yorker* announces that 3 parcels of land at Farmingdale, Long Island, have been purchased as the site of the new state school of agriculture for Suffolk County at a cost of \$87,000.

State Aid for Agricultural Instruction in Tennessee.—An act of the Tennessee General Assembly of 1913 increases the state school fund from 25 to 33½ per cent of the gross revenues, or by several hundred thousand dollars annually. One of the purposes of this increase is to encourage the introduction of agriculture, home economics, manual training, and kindred subjects into county elementary schools under adequate supervision, through supplementing the salaries of supervisors in these subjects. For the present school year \$10,000 will be available for this purpose, and each supervisor may receive therefrom an amount equal to one-half of the salary provided by the county, but not less than \$200 and not more than \$500.

The act also provides that a portion of the state high school fund may be devoted to the encouragement of these subjects in county high schools. The State Board of Education is authorized to apportion to the high school fund of any county in which the proceeds from the high school tax do not amount to \$2,000 in any one year, the amount necessary to make a high school fund of \$2,000, but not, however, to exceed \$1,500 to any one school in any one year, or a total of \$50,000 for all schools. Counties receiving such aid must comply with the regulations of the State Board of Education with reference to purchases, equipment, licensing of teachers, and courses of study.

High School Visitors in Texas.—The board of regents of the University of Texas has recently made provisions for the employment of high school visitors who will give special attention to the development of manual training, domestic economy, and agriculture. The university now accredits all these subjects for admission to the freshman class.

Agricultural and Home Economics Instruction in the Public Schools of Porto Rico.—A recent number of *Porto Rico Progress* announces that a special teacher in agriculture has been provided for every district in the island except San Juan, and teachers of household economics in 48 towns. To provide time for instruction in agriculture, manual training, home economics and other special subjects, the course of study has been rearranged. Boys in the sixth, seventh, and eighth grades will have 3 periods a week for manual training and 2 for agriculture, while the girls in the same grades will have cooking 3 times a week and sewing the other 2 days. To keep the instruction uniform the Department of Education will send out a monthly bulletin outlining the work in these subjects to be taken daily.

University of Manchester.—The new laboratory for research work in agricultural entomology was opened November 13, 1913, by Sir Sidney Olivier, permanent secretary of the Board of Agriculture and Fisheries. A laboratory

room 58 by 28 feet is available, together with a smaller laboratory, an experimental field with greenhouses, etc. Dr. A. D. Imms, formerly forest entomologist of the government of India, has been appointed first reader in agricultural entomology and will conduct researches and supervise the work of research students.

First Horticultural School for Women in France.—The first horticultural school for women in France, a higher school of horticulture for young women, was opened in the latter part of 1913 at Brie-Comte-Robert, near Paris, under the auspices of the Union for the Agricultural and Horticultural Instruction of Women.

Farm Women's Clubs in France.—The minister of agriculture of France has issued a circular addressed to the directors of the departmental agricultural services authorizing them to organize farm women's clubs in as many communities as possible, for the promotion and dissemination of instruction in home economics and agriculture. These clubs are to supplement the instruction given in the 3 months' courses of the home economics schools now operating in France and in the post-scholastic home economics schools, to aid former students of these schools to perfect their studies and to give women in general an opportunity to procure a professional domestic knowledge.

The clubs of each department are to be federated and these departmental federations combined into a national federation of farm women's clubs, to be administered by a central committee at the seat of the ministry of agriculture.

Pomological Experiment Station in South Russia.—A new experiment station for pomology known as the Salghir Station has recently been established in the Crimea in South Russia in the town of Simpheropol. The director of the station is S. Mokshetsky, entomologist. The station is anxious to enter into relations with the pomological and horticultural institutions of the United States.

Proposed Agricultural College in Ceylon.—Plans are being made for the establishment of a Tropical Agricultural College on the grounds of the Gangarooma Experimental Station, where a tract of 400 acres is available. It is estimated that the main college building and equipment and quarters for the staff and students will cost from 300,000 to 400,000 rupees (\$97,300 to \$129,770.) It is expected that the staff of the Ceylon Department of Agriculture will be available for a portion of the instruction work, but that a botanist will also be needed.

Miscellaneous.—The American Phytopathological Society has elected officers for 1914 as follows: President, Dr. Haven Metcalf of Washington, D. C.; vice-president, Dr. F. D. Kern of State College, Pa.; and counsellor, H. R. Fulton of West Raleigh, N. C.

An association of economic entomologists has been formed in Germany and held its first meeting at Magdeburg the latter part of October, 1913. Dr. L. O. Howard was elected an honorary member.

The National Geographic Society has awarded a medal in honor of the late Prof. F. H. King, of the University of Wisconsin, for his well-known work on Chinese agriculture.

Dr. Shosuke Sato, professor and dean of the college of agriculture of Tohoku University, has been designated as the exchange professor of Japan to American universities for 1914.

The Second Annual Conference of Editors of Agricultural Colleges and Experiment Stations will be held at the State University of Kentucky June 25 and 26.

	Page.
Recent work in agricultural science	201
Notes.....	300

SUBJECT LIST OF ABSTRACTS.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

Handbook of biochemistry of man and animal, edited by Oppenheimer.....	201
Handbook of biochemical methods, edited by Abderhalden.....	201
Discussions of the Eighth International Congress of Applied Chemistry.....	202
Researches on cellulose, Cross and Bevan.....	202
Relation of reducing power to fermentation of carbohydrates, Schlichting.....	202
On koji acid, a new organic acid formed by <i>Aspergillus oryzae</i> , Yabuta.....	202
In regard to the proteolytic activity of taka-diastrase, Szántó.....	203
The nature and function of the plant oxidases, Clark.....	203
Investigations in regard to phosphatase, von Euler.....	203
Enzym synthesis.—I, Lipase and fat of animal tissues, Bradley.....	204
Enzym synthesis.—II, Diastase and glycogen, Bradley and Kellersberger.....	204
Enzym synthesis.—IV, Lactase of the mammary gland, Bradley.....	204
Contributions to our knowledge of the vegetable hemagglutinins, Kobert.....	204
The analysis of rare earths and earth acids, Meyer and Hauser.....	205
Application of ammonium carbonate method to Hawaiian soils, Rather.....	205
The determination of colloids in cultivated soils, Hassler.....	205

	Page.
Loss of fat as a result of drying meat, Tamura.....	205
Determination of fat in bread, Grujic.....	205
The polarimetric determination of starch in potatoes, Herles.....	205
Specific gravity as a factor in separation of frozen fruit, Gould.....	206
Honey examination, Witte.....	206
Determination of sucrose in confectionery, Roberts.....	206
A method for the detection of color in tea, Read.....	207
The chloral hydrate test for charlock, Winton.....	207
Progress in chemistry of dairy products during 1911, Siegfeld.....	207
Determining fat in cheese by acid method without use of amyl alcohol, Kooper.....	207
New acid-butyrometric method for fat in dairy products, Hammerschmidt....	208
Estimation of fat in cheese by the "neu-sal" method, Wendler.....	208
Weight of the sugar beet and composition of its juice, Harris and Gortner.....	208
Amount of nitrogen in beets and molasses during the years 1907-1911, Saillard.....	209
Quantitative determination of the bitter substances of hops, Adler.....	209
The detection and estimation of arachis oil, Evers.....	209
A clinical method of estimating calcium in urine and other fluids, Bell.....	210
A new method for detecting methyl alcohol, Raikaw.....	210

METEOROLOGY—WATER.

On some meteorological conditions controlling nocturnal radiation, Sutton.....	211
Some causes and effects of variation in the range of temperature, Sutton.....	211
Nitrogen in rain and snow, Knight.....	211
Dry season and droughts in Rhodesia, Goetz.....	211

EXPERIMENT STATION RECORD.

VOL. XXX.

ABSTRACT NUMBER.

No. 3.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

Handbook of biochemistry of man and animal, edited by C. OPPENHEIMER (*Handbuch der Biochemie des Menschen und der Tiere. Jena, 1913, sup. vol., pp. XII+746, figs. 33*).—This is a supplementary volume to those already noted (E. S. R., 26, p. 306), and includes the following chapters: The General Significance of the Hydrogen Ion Concentration in Biology (uses in biological problems, the hydrogen ion concentration of the body fluids, etc.), by L. Michaelis; Progress Made in the Field of Protein Chemistry, by P. Rona; Nucleic Acids and their Cleavage Products, by C. Brahm; Morphological Constituents of the Blood and Spermatozoa, by A. Kanitz; The Properties of Hemaglobin, by F. Müller; Oxidation Processes in the Living Tissues (processes in slow combustion, including catalytic phenomena, enzymes of respiration, and the physiological significance of respiratory enzymes), by A. Bach; Gaseous Exchange in Organs, Tissues, and Isolated Cells, by A. Loewy; Anaphylaxis, by E. Seligmann; Biochemistry of the Skin, by P. G. Unna and L. Golodetz; Mechanics of Gastric Secretion, by A. Bickel; Internal Secretions of the Pancreas, by S. Rosenberg; New Investigations in regard to Digestion and Resorption of Foodstuffs, by E. S. London; Fetal Hormones, by B. Wolff; The Nervous System and Internal Secretions, by G. Peritz; Biochemistry and Radio-active Substances, by J. Plesch; The Decomposition of Sugar by the Cell, by C. Neuberg; Biochemistry of Growth of Man and other Higher Animals, by H. Aron; Metabolism and Sexuality of the Female, by L. Zuntz; and Parenteral Protein Metabolism, by W. Caspari.

Handbook of biochemical methods, edited by E. ABDERHALDEN (*Handbuch der Biochemischen Arbeitsmethoden. Berlin and Vienna, 1913, vol. 7, pp. XXVIII+912, figs. 198*).—This is the seventh volume of this work (E. S. R., 29, p. 408), and contains the following chapters: The living animal material for biochemical investigations (selecting, obtaining, and keeping under various conditions); the use of secretin for obtaining pancreatic juice; the detection and preparation of methylated amino acids (betains) in animal and vegetable tissues; preparation of some substances of biochemical importance from molasses and molasses slops; the most important methods for examining foods and condiments (a very extensive chapter); the technique of investigating the respiratory gaseous exchange in healthy and diseased subjects; the precipitins and methods of precipitation; the methods of investigating the biochemically important actions of light; microscopic technique; some rapid methods for the examination of blood in urine; the quantitative determination of chlorin ions in blood; the

preparation and detection of glucosids; researches with radio-active rays; and movement of gas and water in the plant (transpiration, root pressure, etc.).

Discussions of the Eighth International Congress of Applied Chemistry (*Orig. Commun. 8. Internat. Cong. Appl. Chem. [Washington and New York], 27 (1912), pp. XIII+190*).—This includes the discussions of the various sections, among them analytical, inorganic, agricultural, and organic chemistry; industry and chemistry of sugar; India rubber and plastics; fermentation; fats, fatty oils, and soaps; paints, drying oils, and varnishes; starch, cellulose, and paper; hygiene; pharmaceutical chemistry; bromatology; biochemistry, including pharmacology; electrochemistry; and law and legislation affecting chemical industry.

Researches on cellulose, C. F. CROSS and E. J. BEVAN (*New York, London, and Bombay, vols. 2, 1906, pp. XI+184; 3, 1912, pp. X+173*).—These are the second and third reports on this topic (E. S. R., 13, p. 916). Volume 2 deals with cellulose as a typical colloid; cellulose as a chemical individual; cellulose and structural forms—dimensions; nitric esters; aceto-sulphates; cellulose-xanthogenic acid; cellulose and alkaline hydrates; theory of dyeing; electrolytic phenomena; constitution of cellulose; hydrocellulose; mixed esters—chloracetyl derivatives of hydrocelluloses, etc.; animal digestion and assimilation of cellulose; destructive fermentations; and technical progress in cellulose industries, and a general forecast of technological developments.

Volume 3 deals with cellulose in relation to biological science; its constitution; cellulose esters, acetate, and comparative studies of acetylation, formyl derivatives, and xanthogenic esters; lignocelluloses, reactions with halogens, constitution, and study of autoxidation; technical developments, textile industries (bleaching, paper making, and commercial jute and "heart-damage"); special industries; artificial fibers, film products, and applications of cellulose acetates. The use of bastol, a product made by treating sawdust with aqueous sulphurous acid, and which is used as a constituent of some cattle feeds in England is also discussed.

Relation of the reducing power to the fermentative capacity of various carbohydrates, E. SCHLICHTING (*Abs. in Orig. Commun. 8. Internat. Cong. Appl. Chem. [Washington and New York], 26 (1912), Sects. VIa-XIb, p. 83*).—The paper gives the results of a large number of experiments from which the author has drawn the following conclusions:

"(1) All results found for the amount of actual fermentable sugars by the fermentation method are generally too low, and form about 1 to 6 per cent less than the real amount of sugars present, excepting in mixtures of equal parts of saccharose and dextrose. (2) Fermentation methods of sugar determination should be invariably carried out with pure cultures of yeasts, under uniform conditions of time, temperature, nature, and quantity of yeast nutrients. (3) Certain real relations undoubtedly exist between the reducing power and the fermentability of sugars which enable the analyst to find the correct amount of fermentable sugars, especially when only 2 carbohydrates (of those mentioned) are present. (4) When more than 2 sugars are present in the solution, the results found for fermentable sugars by their reducing power are from 3 to 6 per cent in excess of the truth."

On koji acid, a new organic acid formed by *Aspergillus oryzae*, T. YABUTA (*Orig. Commun. 8. Internat. Cong. Appl. Chem. [Washington and New York], 25 (1912), Sects. I-Ve, pp. 455-462*).—Large quantities of an acid obtained from *A. oryzae* grown on steamed rice were prepared. Saito has previously described this acid as β -resorcylic-carbonic acid. The empirical formula for the recrystallization product was found by this investigator to be $C_{12}H_{14}O_8$. "From the copper salt, as well as from the acetyl and benzoyl derivatives, the presence of 2 carboxyl and 4 hydroxyl groups in the molecule has also been ascertained, so that

the formula may be written as $C_{10}H_8(OH_4)(COOH)_2$. It is therefore quite different from β -resorcylic-carbonic acid, and so far as the author knows, the occurrence of such an acid in fungi has never been mentioned before." The name kojic acid has since been given to the substance.

In regard to the proteolytic activity of taka-diastrase, OLGA SZÁNTÓ (*Biochem. Ztschr.*, 43 (1912), No. 1-2, pp. 31-43).—The results show that acids in small concentrations affect the action of taka-diastrase, mineral acids having the least effect. Compared with trypsin, it is more susceptible to organic acids, and hydrochloric acid destroys it more quickly.

Inhibition is less by alkalis than by acids, and alkalis do not destroy it. Salts do not, or only slightly, inhibit its action. Neutral salts, such as sodium chlorid, sodium sulphate, and sodium nitrate, do not affect it, but inhibit the activity of trypsin. The same effect was noted with most organic salts, but not with sodium lactate. Dextrose, lactose, and starch do not affect it, while levulose shows a slight inhibition of its activity.

The nature and function of the plant oxidases, E. D. CLARK (*Torreya*, 11 (1911), Nos. 2, pp. 23-31; 3, pp. 55-61; 4, pp. 84-92; 5, pp. 101-110).—"The oxidases are of very wide distribution among the flowering plants, peroxidases, especially, being present in about 75 per cent of all the specimens examined, while oxygenases (direct oxidases) are less widely distributed, being found in one-half of the plants used. Catalase may be said to be universally distributed, since there were only a few cases in which it was not found. The leaves, stems, roots, and food-storage organs of the plants seemed to contain the greatest amounts of the oxidases. The flowers and fruit were in many cases comparatively poor in oxidases. In regard to the fruits this statement must be qualified, because dry seeds of somewhat uncertain age were the only available material of certain species.

"Our experience with a great many parallel tests, using the different oxidase reagents upon a great variety of vegetable tissues, show that all of the reagents seem to detect the same substance or substances, for if one reagent gave a positive test, the others generally acted in like manner. The phenolphthalein and indophenol reagents gave positive results in more cases than the others. This is undoubtedly due to their greater ease of oxidation, for they are spontaneously oxidized by the air. It is probable that in the presence of acid juices in the plant the latter does not form oxidases or else that they are immediately destroyed by the acid. It was shown that the inhibiting effect of acids upon the action of oxidases seemed to be a function of the concentration of the hydrogen ions.

"Among plants the chromogens are found to the greatest extent in certain orders, such as the Liliales, Orchidales, Ranales, and most frequently of all in the latex plants of the Convolvulaceæ, Boraginaceæ, Labiate, Solanaceæ, Rubiaceæ, Compositæ, etc. Active oxidases are also likely to be associated with chromogens in the latex plants. These conclusions are interesting because of the bearing they have upon Palladin's theory that these chromogens play an important part in the respiration and the metabolism of plants."

A comprehensive review of the literature of the oxidases is included.

Investigations in regard to phosphatase, H. VON EULER (*Abs. in Chem. Ztg.*, 36 (1912), No. 138, p. 1353).—This enzyme has the property of combining inorganic phosphoric acid with carbohydrates, forming an organic phosphoric acid ester, glucophose. Glucophose was cleaved both in the intestine and kidney, and was synthesized with extracts of these organs.

Glucophose is considered a catalyzer for sugar cleavage by living yeast and also an intermediary product of this reaction. Judging from this phenomenon it seems reasonable to assume that the cleavage of sugar in the animal organ-

ism occurs in the same way. The reason that we have not been able to determine the specific enzyme bringing about the cleavage of sugar is probably because a number of enzymes are concerned in the process; furthermore, the enzymes are localized in various organs, consequently the cleavage of sugar in the body occurs in various phases. When the equilibrium of one of these phases is destroyed, a sort of diabetes occurs.

Glucophose gives us a means for determining in what part of the cycle sugar combustion is abnormal. With it the weakest phase of the process may possibly be enhanced. Living yeast is incapable of producing glucophose but when phosphatase is liberated from the cell it synthesizes this compound.

The problem of enzyme synthesis.—I, Lipase and fat of animal tissues, H. C. BRADLEY (*Jour. Biol. Chem.*, 13 (1913), No. 4, pp. 407-418, figs. 2).—These tests, which were made with the tissues and fluids of the fish, cat, dog, calf, goat, and adult bovine, indicate that "no broad correlation exists between the fat and lipase content of tissues. Homologous organs in allied species, such as teleost livers, fish muscles, etc., show no parallelism between fat and enzyme. Some of the most active fat-producing tissues are relatively poorer in lipase than many other tissues which never normally contain or produce more than a small percentage of fat. Active mammary tissue affords the most striking example of this when compared with lung, kidney, and muscle tissues." "Instead of being unusually rich in lipase on account of its active secretion of fat, it is found to be about on a par with such other tissues as fish ovaries and testes, spleen, brain, and other gland structures of mammals and invertebrates. Compared with a large number of tissues, active mammary gland is not a tissue rich in lipase; it is only twice as active as blood itself. The fact that active mammary tissue is richer in lipase than inactive, as was pointed out by Loevenhart, is probably due in large measure to its hyperplastic condition during lactation."

"Quantitative comparison of fat and lipase in animal tissues gives no positive evidence in support of the theory of enzyme synthesis."

The problem of enzyme synthesis.—II, Diastase and glycogen of animal tissues, H. C. BRADLEY and E. KELLERSBERGER (*Jour. Biol. Chem.*, 13 (1913), No. 4, pp. 419-423).—The results confirm the findings of H. MacLean,^a who showed that kidney and lungs usually low in glycogen had a high diastatic power. The work was done with the lower form of animals, fish, crustaceans, etc., which are known to be rich in glycogen.

The problem of enzyme synthesis.—IV, Lactase of the mammary gland, H. C. BRADLEY (*Jour. Biol. Chem.*, 13 (1913), No. 4, pp. 431-439).—The results show that the active mammary gland of cats, goats, and rabbits contains no lactose-destroying enzyme. In two cases (goat and cow) there seemed to be a progressive increase of sugar, especially when blood was added to the mixture. This may be due to the presence of a mother (pro) substance as indicated by Porcher (*E. S. R.*, 17, p. 287). Lactase, according to this, does not seem to be responsible for the lactose present in milk.

Contributions to our knowledge of the vegetable hemagglutinins, R. KOBERT (*Landw. Vers. Stat.*, 79-80 (1913), pp. 97-205).—This discusses the chemical nature of ricin and its preparation; the agglutination reaction and its use for detecting castor-bean meal in feed cakes; the chemical nature of antiricin; castor-bean lipase and its action; the action of ricin upon animals; the detection of ricin in feeds which contain other agglutinins and in those stuffs which contain no other agglutinins; crotin, abrin, and robin from common locust seed (*Robinia pseudacacia*), and phasin from other sources; papilionaceous

^a Bio-chem. Jour., 4 (1909), No. 10, pp. 467-479.

plants in which hemolysins instead of phasins are present; and pseudoagglutination.

The analysis of rare earths and earth acids, R. J. MEYER and O. HAUSER (*Die Analyse der seltenen Erden und der Erdsäuren. Stuttgart, 1912, pp. 320, figs. 14*).—This book is divided into a qualitative and a quantitative section, and is devoted to the analysis of rare earths and their acids. It constitutes the fourteenth and fifteenth volumes of B. M. Margosches' series of books on analytical chemistry.

Application of the ammonium carbonate method for the determination of humus to Hawaiian soils, J. B. RATHER (*Jour. Indus. and Engin. Chem., 5 (1913), No. 3, pp. 222, 223*).—After commenting upon what has been reported by Kelley and McGeorge (*E. S. R., 27, p. 7*), it is stated that "the ammonium carbonate method for the removal of clay from humus solutions has given uniformly good results on a number of the soil types of the United States, but on exceptional soils, like some of those of Hawaii, a slight modification of the method is necessary to remove the clay. The modification consists essentially in increasing the amount of ammonium carbonate to 2 gm. per hundred cubic centimeters, and heating for 1 hour."

The determination of colloids in cultivated soils, C. HASSLER (*Sitzber. Naturhist. Ver. Preuss. Rheinlande u. Westfalens, 1911, Nos. 1, Sect. C, pp. 13, 14; 2, Sect. C, pp. 15-24, fig. 1*).—Previously noted from another source (*E. S. R., 26, p. 519*).

Loss of fat as a result of drying meat, M. TAMURA (*Biochem. Ztschr., 41 (1912), No. 1-2, pp. 78-101; abs. in Zentbl. Biochem. u. Biophys., 13 (1912), No. 14-15, p. 567*).—As a result of drying and powdering meat, a loss of fat takes place. The larger the amount of meat, the greater the loss. If alcohol is added during the drying, the loss of fat is considerably reduced.

It is deemed advisable, when working according to Shimidzu's paste method or the powder method, to use no more than 300 gm. of material at one time.

Determination of fat in bread, G. GRUJIC (*Orig. Commun. 8. Internat. Cong. Appl. Chem. [Washington and New York], 26 (1912), Sects. VIa-XIb, pp. 1-3*).—The usual methods proposed for extracting the fat in foods can not be applied to the estimation of fat in bread. Previous drying or finely grinding the sample does not increase the yield of fat, but by extracting the crumb of entirely fresh bread, other than rye bread, almost all of the fat present is extracted. The procedure recommended for all kinds of bread, including old bread, is the following, which is based on Polenske's method:

Five gm. of bread crumbs, moist or previously ground dry, is placed in a 200 cc. flask supplied with a condensing tube, mixed with 50 cc. of water and 2 cc. of a 25 per cent solution of hydrochloric acid (specific gravity 1.125), and heated for 1½ hours in a boiling water bath. After cooling, 1 cc. of a 0.04 per cent solution of methyl orange is added, neutralized with concentrated alkali, acidified with 1 drop of dilute hydrochloric acid, filtered through a small folded filter, and the residue washed with hot water. The filter with its contents is then spread on a watch glass, dried for 2 hours at 105° C., and extracted in a Soxhlet apparatus for 6 hours with ether.

The results obtained with rye bread, white bread, and baked goods prepared with skim and whole milk compare very well with the fat present in the flour from which the products were made.

The polarimetric determination of starch in potatoes, F. HERLES (*Orig. Commun. 8. Internat. Cong. Appl. Chem. [Washington and New York], 26 (1912), Sects. VIa-XIb, pp. 5-10*).—Estimating the amount of starch present in potatoes by the specific gravity method leaves much to be desired, while the methods

depending upon the conversion of the starch into sugar are cumbersome. The polarimetric methods seem to be the most appropriate for this purpose.

For the solution of the starch, the author utilizes hydrochloric acid, which was first pointed out by Effront. A fine paste is prepared of the potatoes with a beet press or chopping machine, and 8.82 gm. (for Mohr's cubic centimeters) or 8.8 gm. (for metric cubic centimeters) of the paste is brought into a 100 cc. flask with the aid of 25 cc. of water, and amid stirring 25 cc. of fuming hydrochloric acid (specific gravity 1.188) is added. The mixture is allowed to stand for about 1 hour, stirring frequently during the interval, and then water is added to make 100.35 cc. This is shaken, filtered, and polarized at 20° C. with a Ventzke-Soleil polariscope. The reading obtained gives the percentage of starch present.

A more rapid method consists of weighing out 9.55 gm. (Mohr's cubic centimeters) or 9.53 gm. (metric cubic centimeters) of the potato paste into a beaker glass. The weighing glass is washed off with 25 cc. of water, dried with a piece of filter paper, and the paper thrown into the beaker; 25 cc. of fuming hydrochloric acid is then added, stirring constantly during the process. This is allowed to stand for 1 hour, stirring the mass during this period, when 50 cc. of water is added, shaken, filtered, and polarized as before.

The specific gravity of citrus fruit as a factor in the separation of frozen fruit, R. A. GOULD (*Abs. in Orig. Commun. 8. Internat. Cong. Appl. Chem. [Washington and New York], 26 (1912), Sects. VIa-XIb, p. 387*).—This reports briefly the results of determining the floaters among 5 varieties of sound oranges and 2 varieties of sound cured lemons. The fruit was floated on alcoholic solutions of various strengths and specific gravities.

"The specific gravity varies with the growing district, the variety, the size, and the time of picking. The limits of variation are too great to allow of the use of any method, dependent upon the specific gravity of the fruit, for the accurate commercial separation of frozen from sound fruit, although any lot of partly frozen fruit can be bettered by proper treatment in alcoholic solutions of the proper gravity."

Tables showing results of attempted separation by floating fruit in 160 proof alcohol and subsequently putting that fruit which floats under diminished pressure and refloating in the same solution are given, also tables showing proximate analyses of sound and frozen oranges of various specific gravities to show additional factors which influence the specific gravity of the fruit.

Honey examination, H. WITTE (*Ztschr. Öffentl. Chem., 18 (1912), Nos. 19, pp. 362-373; 20, pp. 390-397*).—A discussion as to the value of determining the nonsaccharin substances, ash, acidity, saccharose, the presence of Ley's reaction, albuminate, the precipitation according to Lund, the presence of starch sirup, Fiehe's test, Auzinger's reaction, and Thöni's precipitation reaction for judging honey. The complete protocol resulting from the analyses of 53 various kinds of honey is given.

Determination of sucrose in confectionery containing cooked starch and in marshmallows, C. C. ROBERTS (*Abs. in Orig. Commun. 8. Internat. Cong. Appl. Chem. [Washington and New York], 25 (1912), Sects. I-Ve, p. 539*).—After pointing out the difficulties encountered in clarifying solutions of starch paste confectionery and marshmallows, a method is recommended in which dilute alcohol (made by diluting 400 cc. of commercial alcohol to 1,000 cc. with water) is used as a solvent for the sucrose. The normal weight, 26.048 gm. of an average sample of the confectionery, is treated with some of the dilute alcohol until solution has taken place, transferred to a 200 cc. flask, clarified with a solution of subacetate of lead (specific gravity 1.25) or alumina cream, or both,

made up to volume with dilute alcohol, and filtered. The filtrate is then polarized as usual.

For inversion 50 cc. of the filtrate is evaporated to remove the alcohol and then inverted in the usual manner. The sucrose is calculated by Clerget's formula.

A method for the detection of color in tea, E. ALBERTA READ (*Orig. Commun. 8. Internat. Cong. Appl. Chem. [Washington and New York], 18 (1912), Sect. VIIIC, pp. 301-303*).—The method described below was devised for the purpose of detecting color in tea, inasmuch as the chemical methods suggested by Allen, Leach, Villiers, and Collin, and the International Committee for the Unification of Analytical Methods for Food-products can not be used without difficulty where small quantities of color are present, largely because of the masking effect produced by the natural color of the tea. The proposed method has the advantage that it will detect much smaller amounts than are found by the chemical method, although it overlooks traces of color which would be found with a compound microscope. It can be used by persons unskilled in scientific methods, and has the additional advantage of being rapid.

"The articles needed for testing the tea are sieves, 16 to 24 meshes to the centimeter, a spatula or case knife, and a piece of unglazed white paper. A small amount of tea, about 25 to 50 gm., is placed in a sieve and shaken over a piece of white paper. If the tea is tightly rolled, it should be slightly crushed either before putting into the sieve or by rubbing it against the sieve. The dust on the paper is then crushed by dragging over it a spatula or case knife, pressure being applied by the finger to the end of the spatula. This crushes not only the tea dust, but any particles of color which are present. The process of dragging the knife across the paper streaks the color, making it more easily seen. A lens with a magnification of 8 to 12 diameters is useful in detecting the smaller streaks. Sunlight is desirable; bright light is essential for this work. This method will detect any coloring as blue, tumeric or carbon." It can also be employed for determining whether tea has been faced, but instead of the white paper, black, unglazed paper is used, on which the facing leaves a white streak.

The chloral hydrate test for charlock, A. L. WINTON (*Orig. Commun. 8. Internat. Cong. Appl. Chem. [Washington and New York], 26 (1912), Sects. VIa-XIb, pp. 409-411*).—For general use the following reagent and procedure is proposed:

"Dissolve 16 gm. of crystallized chloral hydrate in 10 cc. of water. To the solution add 1 cc. of concentrated hydrochloric acid. In making the test, mount about 10 mg. of the mustard flour (or an equivalent amount of prepared mustard) on a slide in the reagent, heat cautiously (never to boiling) for a moment, and examine under a lens. Note the proportion of fragments of hulls that acquire a carmin red color (charlock) to those not changed in color."

Progress made in the chemistry of milk and dairy products during the year 1911, M. SIEGFELD (*Chem. Ztg., 36 (1912), Nos. 140, pp. 1369, 1370; 141, pp. 1378, 1379; 143, pp. 1394, 1395*).—This deals with the advances made in regard to the chemistry, physiology, and technology of milk and other dairy products. The topics are dealt with under the headings of physiology, general chemistry of milk proteins, fats, sugar, ash, enzymes, tests for detecting heated milk, and cream, butter, and milk preparations.

New method for determining fat in cheese by the acid method without the use of amyl alcohol, W. D. KOOPER (*Milchw. Zentbl., 41 (1912), No. 24, pp. 753-757*).—It is a well-known fact that the use of amyl alcohol is undesirable, particularly because it forms compounds with some of the cheese particles

which go over into the fat in varying amounts. Accordingly, a method is proposed which does away with the use of amyl alcohol and at the same time is easy to operate, is exact, uses a low concentration of sulphuric acid, and is not influenced by high temperatures.

In the method 6.5 cc. each of sulphuric acid of specific gravities 1.54 and 1.82 are used. After adding the weaker acid, the butyrometer is heated in a water bath at the temperature of boiling water until the cheese has been dissolved; then the stronger acid is added. After the solution shows a light brown to violet coloration, it is centrifuged at 1,000 revolutions per minute for 5 minutes, placed in the water bath at 70° C. for a short time, and the fat column read off. It is necessary that the fat be clear, that no plug formation has taken place, and that the color of the fat is a faint pink to a very light brown.

The results of examining 20 different kinds of cheese in various stages of ripeness are given, and compared with the results obtained by the gravimetric method.

New acid-butyrometric method for determining fat in cheese and dairy products, HAMMERSCHMIDT (*Milchw. Zentbl.*, 41 (1912), No. 24, pp. 757-763, fig. 1).—The author noted that when sulphuric acid was allowed to act upon amyl alcohol a compound was formed which was finally calculated as fat in the acid-butyrometric method. Amyl alcohol can also go over into the fat as such and cause certain errors in the final calculation.

In order to eliminate the use of amyl alcohol or acetic acid, which is employed in some methods, the author has previously reported on a modification of the Burstert (E. S. R., 21, p. 523) method. Not finding this method suitable on account of the cumbersome apparatus which it employs, he has now devised a new method which can be used with an apparatus similar to the butyrometer. He found that when certain criteria are adhered to in regard to decomposing casein, the casein may be dissolved in a special solution of borax (strength not given). If sulphuric acid and amyl alcohol are then carefully added, satisfactory results are obtained.

A number of analyses were made of cheese, the results of which are reported.

Estimation of fat in cheese by the "neu-sal" method, O. WENDLER (*Milchw. Zentbl.*, 41 (1912), No. 24, pp. 763-765).—A description of a new butyrometer for estimating fat in cheese. The solvent used is composed of a salicylate and hyposulphite. For clarifying the fat butyl alcohol is employed.

On the relationship between the weight of the sugar beet and the composition of its juice, J. A. HARRIS and R. A. GORTNER (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 3, pp. 192-195, figs. 3).—It is believed that the relation of the size of beet to sugar yield has been too little studied. The studies have been conducted, the authors believe, by inadequate methods, and consequently it seemed of importance to measure the intensity of this relationship on the -1 to +1 scale of the coefficient of correlation; also to write the regression equations showing the absolute change in solids, sugar, or purity, associated with a unit change in weight of the beet.

"Suitable published data seem all but wanting. In many series the weights given are averages, without specification as to the number of beets included. Analyses have been made by the thousands, and in some cases upon uniform material drawn from the same cultural conditions, but [the authors] have not been able to obtain such records, either published or in manuscript."

The data analyzed by statistical methods were obtained from Bulletin 39 of the Division of Chemistry of this Department (E. S. R., 5, p. 1004), and Bulletin 32 of the Nevada Experiment Station (E. S. R., 9, p. 349). The beets considered were Klein Wanzlebener, Improved Klein Wanzlebener, Vesbesserten Klein Wanzlebener, Vilmorin Ameliorée, and Desparez.

"Considering the shortness of the materials upon which they are based, these results are surprisingly consistent throughout. They show that composition and purity are very closely correlated with weight, and in such a way that as weight increases, total solids, sucrose, and percentage purity fall rapidly. The rate of fall on the relative scale of -1 to $+1$ is shown by the coefficient of correlation r , the rate in an absolute scale by the second term of the regression equation."

Graphs of most of the equations were prepared, and while the empirical means are very irregular, there is no evidence to show that the regression is other than linear.

The amount of nitrogen in beets and molasses during the years 1907-1911, SAILLARD (*Bul. Soc. Nat. Agr. France*, 72 (1912), No. 6, pp. 545-550).—The methods of sampling and analyzing beets are described. The beets harvested in 1911 were found to contain much more total albuminoid, ammoniacal, amido, and injurious nitrogen than has been observed in previous years. This is supposed to be due to the dry season. A large amount of nitrogen in beets has a tendency to reduce the sugar yield and to increase the yield of molasses. Certain technical difficulties are also encountered in the use of beets high in nitrogenous substances.

Quantitative determination of the bitter substances of hops, L. ADLER (*Ztschr. Gesam. Brauw.*, 35 (1912), No. 35, pp. 406-410; *abs. in Jour. Soc. Chem. Indus.*, 31 (1912), No. 20, p. 1003).—This is a modification of Lintner's method (*E. S. R.*, 11, p. 22), and consists of boiling 10 gm. of hops, previously disintegrated in a chopping machine, for 7 hours with 200 cc. of petroleum ether (boiling point 48° C.). After cooling, the extract is made up to 255 cc., and 50 cc. of the filtered liquid is titrated with tenth-normal potassium hydroxid solution, using 10 drops of a 1 per cent solution of phenolphthalein as the indicator. The titration is finished when the yellowish brown layer, after thoroughly shaking, has a carmin red tint. The volume of tenth-normal alkali solution used, multiplied by 2, gives the percentage of bitter substances present in the hops. If necessary, the boiling point of petroleum ether can be adjusted to 48° by adding benzin, etc. A variation of 10° in the boiling point, however, was found to make a difference of only 0.5 per cent in the bitter substances.

The detection and estimation of arachis oil, N. EYERS (*Analyst*, 37 (1912), No. 440, pp. 487-492).—The method recommended for the estimation of arachis (peanut) oil is as follows:

"Weigh out 5 gm. of the oil into a saponification flask, and 25 cc. of alcoholic potash (80 gm. potash dissolved in 80 cc. water and diluted to a liter with 90 per cent alcohol), and saponify for about 5 minutes under a reflux condenser. To the hot soap solution add 7.5 cc. of acetic acid (1 volume of glacial acetic acid to 2 volumes of water) and 100 cc. of 70 per cent alcohol containing 1 per cent (by volume) of hydrochloric acid, and cool to 12 to 14° C. for an hour. Filter and wash with 70 per cent alcohol containing 1 per cent hydrochloric acid at 17 to 19° , the precipitate being broken up occasionally by means of a platinum wire bent into a loop. The washing is continued until the filtrate gives no turbidity with water, the washings being measured. Dissolve the precipitate, according to its bulk in 25 to 70 cc. of hot 90 per cent alcohol, and cool to a fixed temperature between 15 and 20° . If crystals appear in any quantity, allow to stand at this temperature for 1 to 3 hours, filter, wash with a measured volume of 90 per cent alcohol (about half the volume used for crystallization), and finally with 50 cc. of 70 per cent alcohol. Wash the crystals with warm ether into a weighed flask, distill off the ether, dry at 100° , and weigh. If the melting point is lower than 71° , recrystallize from 90 per cent alcohol. Add the correction for the solubility in 90 per cent alcohol as in Renard's

process from the table given by Archbutt (Allen's Commercial Organic Analysis, 4. ed., vol. 2, p. 94), and also for the total volume of 70 per cent alcohol used in precipitating and washing (including the 100 cc. added in the first instance).

"If there are no crystals from 90 per cent alcohol, or if they are only in very small amount, add a sufficient quantity of water to reduce the strength of the alcohol to 70 per cent (31 cc. water to 100 cc. 90 per cent alcohol). Crystallize at 17 to 19° for an hour, filter, wash with 70 per cent alcohol, and weigh as before, adding the correction for 70 per cent alcohol. If the melting point is below 71°, recrystallize from a small quantity of 90 per cent alcohol, or again from 70 per cent alcohol.

"The following oils gave no crystals: Olive oils, including 'nice superfine,' 'nice seconds,' 'Malaga,' and 8 of unknown origin, almond, poppy, and rape oils."

A clinical method of estimating the amount of calcium in the urine and other physiological fluids, W. B. BELL (*Bio-chem. Jour.*, 6 (1912), No. 3, pp. 205-209, figs. 2).—Finding that the precipitates obtained with oxalic and acetic acids for many specimens of urine were pure calcium oxalate, providing the proper precautions as regards phosphates were observed, a method was devised for determining the calcium in urine and similar fluids.

"A sample from a 24 hours' specimen of urine is made faintly acid with hydrochloric acid to dissolve any insoluble phosphate present. It is then made faintly alkaline with ammonia, and filtered. Next 5 cc. of the filtrate is placed with a pipette in the special centrifuge tube, which is of the usual size and shape in the upper portion, but tapers at the lower end into a cylindrical extremity of even bore (1.25 mm.) and calibrated into 1 mm. divisions. A line, with 'urine' marked below it, encircles the upper part of the tube at the 5 cc. level. Any air bubbles which may collect in the calibrated portion are got rid of with a fine wire or strand of silkworm gut. Then 1 cc. of the reagent, consisting of a saturated solution of oxalic acid in a 5 per cent solution of acetic acid, is added. The correct quantity of reagent (1 cc.) is also indicated by a line round the tube, which is marked 'reagent.' Finally 2 cc. of alcohol or methylated spirit, as indicated by the line marked 'alcohol,' is added, and the contents of the tube are thoroughly mixed by shaking.

"The second tube is then taken, and 5 cc. of the standard solution (0.05 gm. of calcium phosphate, $\text{Ca}_3(\text{PO}_4)_2$, is dissolved in a little hydrochloric acid. Make alkaline with ammonia and acid with acetic acid. Add 2 gm. of urea to the solution, and dilute the whole up to 100 cc. with distilled water; specific gravity, 1.015) is run into it with a pipette that is up to the line marked 'solution,' and any air bubbles removed as before. Next the reagent and alcohol are added, as in the case of the first tube, and the whole is thoroughly shaken. Both tubes, with their calibrated end packed in wool, are then carefully placed in the opposite buckets of a centrifuge, and are centrifuged for about a quarter of an hour. On removing the tubes the precipitate will be found to stand at a certain height, say 10 mm. in the 'standard-solution' tube, while it may stand at 7 mm. in the other, which contains the urine to be examined. As a rule, there is a slight slant on the surface of the deposit. This can be obviated by stopping the machine at the end of 1 or 2 minutes and turning the tubes through half a circle."

When the method was compared with the usual chemical method for determining calcium it was found that the greatest difference never amounted to more than 1 per cent of the quantity present in the sample.

A new method for detecting methyl alcohol, P. N. RAIKAW (*Orig. Commun. 8. Internat. Cong. Appl. Chem. [Washington and New York], 25 (1912), Sects. I-Ve, pp. 417-419*).—The method is based on the behavior of nitromethan and

its immediate homologues toward sodium nitroprussid in an alkaline (ammoniacal) solution. If a few drops of sodium nitroprussid are added to a solution containing nitromethan an indigo blue coloration is produced.

A procedure for applying this test for the detection of denatured alcohol is also described.

METEOROLOGY—WATER.

On some meteorological conditions controlling nocturnal radiation, J. R. SUTTON (*Trans. Roy. Soc. So. Africa*, 2 (1912), pt. 5, pp. 381-393).—This paper is based upon observations at Kimberley during a period of 8 years with 2 radiation (spirit) thermometers, one placed upon the grass and the other mounted on a light brass stand 5 in. above the grass.

The general conclusion reached is "that after allowance has been made for the state of the sky and the movement of the air, the only factor of real importance determining the magnitude of the radiation-temperature gradient is the relative humidity. The absolute humidity, as such, is unimportant."

Some causes and effects of variation in the range of temperature, J. R. and ELIZABETH M. SUTTON (*Trans. Roy. Soc. So. Africa*, 2 (1912), pt. 4, pp. 341-356).—This paper presents the results of a study of what variation if any of the diurnal curve of barometric pressure accompanies a greater or less range of temperature as night follows day.

Nitrogen in rain and snow, N. KNIGHT (*Proc. Iowa Acad. Sci.*, 18 (1911), pp. 75-77).—The results of analyses with reference to the nitrogen content of 9 samples of snow and 8 samples of rain collected at Mount Vernon, Iowa, during 8 months, excluding May, June, July, and August, of 1910 are given. The total amount of nitrogen brought down to the soil by precipitation during this period was 13.71 lbs. per acre.

Dry season and droughts in Rhodesia, E. GOETZ (*Rhodesia Agr. Jour.*, 10 (1913), Nos. 4, pp. 538-544; 5, pp. 691-698; 6, pp. 828-832).—The rainfall throughout Rhodesia during the dry season for a number of years is summarized and the conclusion is reached that there is no useful rainfall from April to October, inclusive. Droughts of more or less severity also occur during the so-called rainy season, a fortnight or more without rain or 20 to 25 days with not more than $\frac{1}{2}$ in. of rain being considered a drought. The distribution of droughts throughout the year for a series of years is shown. Changes in farm practice better to adapt them to weather conditions are discussed.

The regime of underground waters in the neighborhood of Polesia, E. V. OPROKOV (*Pochvovîdîniye (Pédologie)*, 15 (1913), No. 2-3, pp. 29-57, pl. 1).—Nine years' observations are reported on ground water level and the factors affecting it made on three wells in the immediate neighborhood of Polesia in the Province of Minsk. The variations in ground water level and the effects of atmospheric precipitation, evaporation, and temperature on its position are graphically represented.

From his observations the author concludes that the atmospheric precipitations have a marked influence on the height of ground water level, which is manifested within a short time, generally not more than a month after precipitation during the warm months. He further concludes that the sinking of the ground water level during the dry years was due entirely to loss by evaporation, etc., that the rise of water level during the wet years was due to the recuperation of the average quantity of soil moisture during the rainy periods following the dry periods, and also that the excess water of a rainy year is held in reserve for the dry year or years following.

Water supplies, with special reference to underground water, L. K. WARD (*Jour. Dept. Agr. So. Aust.*, 17 (1913), No. 4, pp. 494-504).—Referring especially

to South Australian conditions the author briefly discusses rainfall, its use and loss, artesian water, artesian basins, the salt content of rain, ground water, well types, factors determining quantity and quality of water, well location and protection, tanks, and the use of the divining rod. Observations made in New Zealand are said to prove that every inch of rain falling over an acre of ground deposited $4\frac{1}{4}$ lbs. of salt.

The advice of a geologist is considered preferable to that of a diviner in locating underground water supplies.

SOILS—FERTILIZERS.

The geology of soils and substrata with special reference to agriculture, estates, and sanitation, H. B. WOODWARD (*London and New York, 1912, pp. XVI+366, pls. 4, figs. 44; rev. in Science, n. ser., 38 (1913), No. 983, pp. 626, 627*).—This book gives an outline of geology in its broader relations with agriculture and sanitation, and discusses the preparation of geological maps and soil surveys; soils, subsoils, and substrata; weathering of rocks and subsidences; the climatic conditions affecting soils and their handling; chemical composition and physical properties of soils; the use of mineral fertilizers and amendments; forests and woodlands, and their associated geological features; orchards, gardens, and vineyards; geological considerations concerning minerals and other economic materials; house sites, water supply, sewage, and drainage; and geological formations of England in their relation to the above subjects.

The object of the book is stated to be "to provide such information relating to the land-surface as will be useful to students and teachers of agriculture, to those occupied in the management of estates and farms, or in sanitary and engineering works, wherein it is important to consider the geological nature of different sites for residences and other purposes." Special emphasis is laid on the importance of a knowledge of the underlying formations in the study of soils. It is maintained that a soil map to be of most value must deal not only with the surface soil, but must take into account the subsoil and show the depth as well as the nature of the soil. "A map of the surface soils alone would give a very imperfect idea of the capabilities of the land. . . . A good subsoil map which shows the variations in the strata, whether drifts or the more regularly stratified formations, will always indicate the general distribution of the surface soils."

The germs of pedology in antiquity, A. JARILOW (*Internat. Mitt. Bodenk., 3 (1913), No. 2-3, pp. 240-256*).—This article reviews the ancient ideas regarding biology and physics of soils.

Progress in agricultural chemistry (especially soil chemistry) since the use of the newer results of physical chemistry, especially colloid chemistry, H. BREHM (*Kolloid Ztschr., 13 (1913), No. 1, pp. 19-35*).—This article discusses in some detail the significance of colloid chemistry in relation to soils, mineralogy, and geology. The chief soil colloids enumerated are humus, slime organisms, colloidal iron and aluminum hydroxids, weathered amorphous silicates, and bacteria and micro-organisms held in suspension. The chemistry of colloidal humus in soils and the influence of lime and humus on the adsorptive power of cultivated soils are taken up in turn, followed by reviews of numerous works on the quantitative determination of soil and decomposed rock colloids.

It is thought that colloids play an important part in the exchange of bases when plant food is added to the soil by entering into the so-called adsorption combinations which are essentially different from ordinary chemical combinations. These colloidal cementing substances or adsorption combinations are

considered to be the food bearers of the soil. Too much or too little of the colloidal substances is said to impair the agricultural value of a soil.

The possibility of judging soils by their natural vegetation on the basis of the theory of probability, P. VAGELER (*Pflanzer*, 9 (1913), No. 4, pp. 171-184; *abs. in Chem. Zentbl.*, 1913, II, No. 4, pp. 378, 379).—From a mathematical demonstration, based on the assumption that the quantitative relations between soil and plants depend primarily on the physical properties of the soil, especially its hygroscopicity, it is concluded that the theory of probability combined with rigorous adjustment of the errors of probability is applicable for judging soils whose types of physical structure and plant forms lie within certain extreme limits established by actual test. This method was tested using hygroscopic values of some of the representative extreme soil formations of German East Africa, having correspondingly distinct vegetation.

It is concluded in general, from results obtained, that plant forms are regulated by those physical properties of the soil which regulate the hygroscopic water, and that under the same conditions of climate and with the same plant forms the same soil properties will appear with a regularity which will vary practically as indicated by the numerical probability error. It is further concluded that this method not only places the judging of soils by their characteristic vegetation on an exact numerical basis and reduces the number of actual tests, but offers a useful method for tracing soils in open plain areas.

Soil texture, C. T. GIMMINGHAM (*Chem. World*, 2 (1913), No. 6, pp. 187, 188).—The opinion is expressed that from all points of view the mechanical analysis serves as a good basis for the classification of soils, but that the results of such analysis can be of use only with a full knowledge of local conditions since the textures of identical soil types often vary from field to field. In this connection it is suggested that the percentage of shrinkage of soils on drying be determined.

White soil (Molkenboden), R. HORNBERGER (*Internat. Mitt. Bodenk.*, 3 (1913), No. 4, pp. 353-357).—The author reports his own and reviews other investigations on a rather impermeable grayish white soil, which he concludes is derived from sandstone but is somewhat poorer in soluble potash and lime and richer in phosphoric acid than an ordinary sandy loam derived from sandstone.

Marsh of the southern Vendée.—The influence of inundation on the fertility, G. CHARTRON (*Bul. Soc. Sci. Nat. Ouest France*, 3. ser., 2 (1912), No. 3-4, pp. 125-132).—In discussing the fertility of the soils of these flats it is stated that in the spring a kind of alga grows in the stagnant drainage water on the flats, forming a slime coating on the soil after the water has disappeared which is said to vary in amount from 214 to 1,158 lbs. per acre. Analyses of samples show considerable nitrogen and lime but relatively little phosphoric acid and potash. Analyses of soils from the surrounding slopes and of the drainage water lead to the conclusion that the fertility of the swamp soils is due more to the drainage water than to the slime.

Preliminary report on the soils of the wine district of Arad-Hegyalja and of the Arad plains, P. TREITZ (*Jahresber. K. Ungar. Geol. Reichsanst.*, 1910, pp. 214-243).—A discussion of geology and meteorology in their relations to the soil formations of these regions is followed by descriptions of the different types of soil encountered in both hill and plains country. The soils of the hill country are divided into soils rich in humus and iron, calcareous soils, brown forest soils, and podzol soils. The plain soils are discussed as sand and gravel soils, light brown and dark brown desert soils, prairie clay, and alkaline soils.

The soils of the rocky deserts of Turkestan, S. S. NEUSTRUEV (*Pochvovedenie (Pédologie)*, 15 (1913), No. 1, pp. 1-19).—This article discusses in some detail the geological formations of the rocky deserts of Turkestan in their

relation to climate, vegetation, and soil formation. Analyses of some of the soils of these regions show large quantities of gypsum, less sodium sulphate, and some sodium chlorid. The quantity of sodium sulphate is said to be sufficient to limit the vegetation to desert plants. An abundance of gypsum is observed principally where excess moisture is contained in the soil. For this reason the salt deposits are said to be due to the evaporation of atmospheric water and not to subterranean waters, although the formation of underlying salt crusts under the influence of subterranean waters is frequent.

Tamar River soils, H. J. COLBOURN (*Agr. and Stock Dept. Tasmania, Rpt. 1912-13, pp. 18, 19*).—Analyses of basaltic and nonbasaltic soils from the Tamar River Valley are reported with brief comments on their fertilizer needs.

Soil formation in clays of humid regions, B. FROSTERUS (*Internat. Mitt. Bodenk., 3 (1913), No. 2-3, pp. 99-130, figs. 11*).—Investigations of the physical and chemical composition of podzol soils found in clay soil deposits in swampy regions are reported. These included a study and comparison of the different layers of these soils and the conditions which determine their character.

It was found that in many cases two genetically different divisions exist in podzol soils, an upper and a lower. The upper part, which may be considered the podzol proper, is divided into two zones, one composed of layers of humus and of kaolin, the other composed of sedimentary earth and ortstein (hardpan) formations. These layers are formed by the leaching down of the soils from above. The kaolin layer is in an advanced state of weathering and is characterized by a high silica content. The layers of the second zone are especially rich in humus, clay and iron, and leachings of magnesia and alkalis.

The location and condition of the lower part of the podzol soil is determined by the ground-water level, and in some cases this influence extends to the surface soil, giving rise to the so-called ground-water soils. In localities where the ground-water level is high and where forest swamps are common such soils take an important place, replacing the true podzol soils. Where they lie near the surface they exercise a bad influence on plant growth. The true podzol formation is directly opposed to the ground-water soil formation.

The constituents of clay which impart plasticity and cohesion, A. ATTERBERG (*Internat. Mitt. Bodenk., 3 (1913), No. 4, pp. 291-330, figs. 2*).—In a report of extensive investigations of the causes of plasticity, toughness, and firmness of clays of northern and southern Europe the author defines plasticity, consistency, and stickiness as applied to clay, reviews the investigations and conclusions of other experimenters, and reports the results of his own tests of a large number of mineral samples and chemical preparations made to determine the principal plastic constituents in these clays. The minerals biotite, hematite, and limonite, and mixtures of hematite or limonite with kaolin showed typical clay plasticity combined with a high degree of toughness, as did also ferric oxychlorid (dialyzed iron).

Those minerals and preparations which appeared plastic showed a leafy or scaly structure from which it is concluded that the particles of leafy or scaly form impart plasticity to a mineral. A high degree of toughness was found in washed products of biotite, hematite, and limonite, as was also a high degree of firmness on drying in fine washed products out of the same materials. Since firmness was not found in all of these products it is concluded that a high degree of firmness is a property only of the scaly shaped particles of colloidal size.

Since the clays of northern Europe contain biotite in both oxidized and unchanged form it is generally concluded that colloidal biotite washings form their chief constituent and explain their high plasticity. The clays of southern Europe apparently owe their plasticity to their high content of hematite and limonite and mixed hematite or limonite with kaolin.

Comparative investigations of the cohesive power of different kinds of soils, H. PUCHNER (*Internat. Mitt. Bodenk.*, 3 (1913), No. 2-3, pp. 141-239, figs. 2).—The author describes methods and apparatus used and gives the results of tests of the cohesive power of a large number of soil samples from different depths.

A summary of results indicates that the samples tested showed wide variations in cohesive power, which in the great majority of cases was more marked in the upper strata of soil than in the deeper ones. Investigations on the effect of mechanical composition of soils on their cohesive power showed that coherence increased with a decrease of the coarse sand and an increase of fine silt. The coarser silt (0.01 to 0.25 mm.) increased cohesive power in coarse-grained soils with an excess of sand. On the other hand, too large a proportion of the coarser silt in fine-grained soils decreased the cohesive power. The sand separates of different grades (0.25 to 3 mm.) generally decreased cohesive power. The cohesive power of dry soils was affected to a considerable extent by chemical and biological influences as well as by the physical properties of the individual soil constituents.

Physico-chemical studies of soils.—II, The hygroscopicity of soils, U. PRATOLONGO (*Staz. Sper. Agr. Ital.*, 46 (1913), No. 3, pp. 219-240, pls. 3, figs. 2).—In a systematic study of the hygroscopicity of six soils, it was found by physical and mechanical analyses and by a determination of variations in water vapor tension in the soil under fixed and variable temperatures that the physical and chemical structure as well as the humus content of the soils directly affected the processes of dehydration and rehydration.

Relation between the hygroscopicity and the chemical composition of certain Java soils, J. SCHUIT (*Meded. Proefstat. Java-Suikerindus.*, 4 (1913), No. 10, pp. 225, 226, table 1, pl. 1; *Arch. Suikerindus. Nederland. Indië*, 21 (1913), No. 24, pp. 713, 714, pl. 1, table 1; *abs. in Chem. Abs.*, 7 (1913), No. 21, p. 3635).—By hygroscopicity of the soil is here understood the number of grams of water which 100 gm. of oven-dry soil absorbs in 14 days in vacuum over 10 per cent sulphuric acid. With such of the soils as had hygroscopicity of less than 10.5 there was remarkable regularity in that the moisture, the organic matter, the nitrogen, and the lime rose with the hygroscopicity and the phosphoric acid soluble in hydrochloric acid and that soluble in citric acid fell, while the potash dissolved by these two solvents first rose, then fell. With soils showing a hygroscopicity above 10.5 the same relation was observed in the first named constituents, while with the phosphoric acid and the potash there was less regularity.

Quantitative determination of the absorbed bases in the soil, D. PRANISCHNIKOW (*Landw. Vers. Stat.*, 79-80 (1913), pp. 667-680, pl. 1, fig. 1; *abs. in Zentbl. Agr. Chem.*, 42 (1913), No. 5, pp. 296-298).—Under the assumption that soil constituents are in the form of available plant food only when in an absorbed condition, experiments were made to determine the efficiencies of ammonium nitrite, acetate, hydroxid, carbonate, and chlorid for determining the quantities of available potassium in soils. The nitrite showed a stronger reaction than the chlorid, but was considered unsatisfactory on account of its unstable character. In this respect the acetate and hydroxid gave better results than the nitrite, although the energies of reaction were about the same. The carbonate was less suitable on account of the organic matter in the soils.

For determining quantities of available ammonia four methods were compared, as already noted by Reschetnikov (*E. S. R.*, 28, p. 111).

A rich black soil, a loam, and a podzol soil were treated with ammonium nitrate to determine the quantity of absorbed lime. The rich black soil was

found to be fairly rich in lime while the other two were comparatively poor, especially the podzol.

In tests of certain potassium-containing silicates as sources of available potassium, biotite, muscovite, and nepheline when treated with ammonium chlorid and barium chlorid showed relatively large quantities of available potassium while orthoclase, sanidin, microclin, and leucite were very poor in this respect. However, it is stated that a quantitative comparison can not be made by these results since the different potassium silicates and zeolites are said to be in variable states of stability regarding potassium. An artificial sodium zeolite was treated with potassium and ammonium chlorids in order to get the corresponding potassium and ammonium zeolites. Pot tests with buckwheat of these and other silicates showed that the potassium in the zeolites, as also in the biotite and nepheline, was largely in available form, but this was not so when the zeolites were protected from contact and reaction with the other plant food salts, a strong fixation of the potassium being apparent. In this case the addition of calcium carbonate worked satisfactorily in converting the potassium compounds into available form as did also mixtures of the salts of other foods.

The so-called isolation method was used to test the effect of the various silicates when not in contact with other plant food compounds in the soil. In this method two concentric cylinders are used, the inner being much smaller and somewhat shorter than the outer. Some of the roots of the plant are placed in the inner cylinder which is filled with sand containing only the silicate to be tested. The rest of the roots are allowed to grow in the sand which fills the outer cylinder to the top and is supplied with all necessary elements of plant food except that added to the inner cylinder. The top of the latter is closed so that there is no interchange of plant food between the cylinders. In this way the plant was forced to draw its potash supply from the silicate in the inner cylinder without the aid of the solvent action of other fertilizing substances.

Experimental investigations on the question of precipitation of iron in podzol soils, B. AARNIO (*Internat. Mitt. Bodenk.*, 3 (1913), No. 2-3, pp. 131-140).—Experiments made to determine the movements of iron in podzol soils showed that it moves in such soils in ferrous forms reduced from ferric salts by humus solutions and as iron colloid solutions in soil solutions which are poor in electrolytes and show a high humus content, as is the case in sandy podzol soils. The iron sinks into the deeper layers of such soils and forms ortstein when conditions are favorable for precipitation. It is also shown that iron can be precipitated by electrolytes, of which sulphuric acid and silicic acid are the most prevalent in this soil, and by colloidal silicic acid and humus. The electrolytes and colloids are said to effect precipitation only within fixed limits of concentration of the solution to be precipitated. The colloid iron is said to diffuse through the upper part of the soil and is there precipitated by humus and electrolytes. This explains the presence of so much iron in the upper layers of podzol soils.

Iron in the ground water in the form of salts of mineral acids rises through capillarity and is precipitated in the upper layers of the soil.

Work of the chemical laboratory of the Ploti Experiment Station, 1912, S. SKALSKIĬ (*Godichnyi Otchet Ploti. Selsk. Khoz. Opytn. Stantsii*, 18 (1912), pp. 133-227, 349-380, pls. 3).—The work reported included bacteriological as well as chemical studies of the soil. The intensity of the process of the fixation of nitrogen in the soil under different cultural conditions; the intensity of the processes of nitrification and denitrification in tilled and untilled fallow; and the conversion of easily soluble phosphoric acid into insoluble form under the influence of chemical and microbiological factors were studied in field and

laboratory. In addition, a series of cropping experiments was conducted to determine (1) the influence of sterilized soils on the development of plants and (2) the proportions of nitrogen and phosphoric acid most favorable for plant development. Studies were also made of the relation of nitrogen and phosphoric acid to soil fertility.

The fixation of nitrogen by soil bacteria was found to depend on the cultural condition of the soil, the intensity of the process increasing with the degree of culture. It was higher in spring (tilled) fallow soil than in untilled, and higher in the surface soil than in the subsoil of all the soils tested.

Determination from time to time of nitric nitrogen in soil and subsoil indicated that the intensity of nitrification was much less in the cultivated top soil than in the subsoil of both tilled and untilled fallow except for a few days at the beginning of the tests, while the opposite was true of denitrification. Studies of the processes of nitrification and denitrification in identical samples of soil, however, indicated that when conditions were made favorable in the soil for the growth and activity of nitrifying bacteria a medium was formed with the resulting nitrates which was favorable to the growth and activity of denitrifying bacteria which in turn destroyed the nitrates already formed. It was further found that some of the nitric nitrogen formed was converted into albuminoids or into gaseous nitrogen. Some of the latter may be fixed by nitrogen-fixing organisms and pass into complex organic forms.

In addition to the results obtained in the preceding year in regard to the chemical and microbiological fixation of soluble phosphoric acid (E. S. R., 28, p. 417) it was found that the fixation of easily soluble phosphoric acid depends as much on chemical as on biological factors, and the intensity of this process depends directly on the cultural condition of the soil. The total fixation through both chemical and microbiological factors was found to be greater in subsoils than in cultivated top soils as was also the case where the fixation was due to chemical factors alone, but when due to microbiological factors alone the intensity was found to be the greater in the top soil.

Sterilization of soils with chloroform and with heat, as previously noted, increased the crop yield by converting the phosphoric acid and nitrogen into available forms. The crop yield increased with the nitrogen added; but with increased phosphoric acid there was first an increase, then a decrease. Increasing both fertilizers slightly increased the crop.

Fallow soil was found to be in the best physical and chemical condition, and phosphoric acid was more needed as a fertilizer in this soil than nitrogen, although both are considered indispensable in raising the soil to a high degree of fertility.

Bacterial action in the soil as a function of food concentration and of insoluble organic substance, O. RAHN (*Centbl. Bakt. [etc.]*, 2. Abt., 38 (1913), No. 19-20, pp. 484-494).—This work is a continuation and completion of studies previously noted (E. S. R., 29, p. 817), and is devoted chiefly to a study of the influence of porous spongy substances, such as cellulose, on bacterial activity in soils. Cellulose in the form of finely grated filter paper was mixed with sand, washed with hydrochloric acid, in different proportions. These mixtures and likewise sand without cellulose were moistened with a 5 per cent peptone solution, and a peptone solution without sand addition was also used in each series. These different combinations were sterilized in the autoclave and inoculated with a culture of *Bacillus mycoides*. The cultures were analyzed after 2, 4, 6, 10, and 20 days' incubation and the progress of decomposition and the different speeds of transformation in the individual combinations noted. The influence of the concentration of peptone and of variations in water content and of cellulose on the ammonification are specially noted.

From the results obtained it is concluded that the bacterial activity in soil depends on the size of soil grains, the water content, and the concentration of food. The speed and the final stage of decomposition vary with these three factors.

In order to obtain physiologically comparable results it is shown that the soil solution must contain the same food concentration in all experiments, which does not correspond with conditions in cultivated soil. With the same food concentration in the soil the decomposition of some substances shows approximately under all conditions the same final point of cleavage, so that only the speed of decomposition and not the final stage is influenced by the size of grain and water content. This was found to be the case in the decomposition of peptone by *B. mycoides*. However, with other bacteria in previous experiments the speed of decomposition and also the point of final decomposition were influenced by the physical properties of the soil.

Coarse spongy organic substances, such as decomposed cellulose, acted in dry soils as water absorbers and diminished the bacterial action, but in moist soils they increased ventilation and thereby increased the activity of aerobic bacteria.

Occurrence of *Azotobacter* in tropical soils, J. GROENEWEGE (*Meded. Proefstat. Java-Suikerindus.*, 4 (1913), No. 13, pp. 241-244; *Arch. Suikerindus. Nederland. Indië*, 21 (1913), No. 26, pp. 790-793; *abs. in Chem. Abs.*, 7 (1913), No. 21, p. 3635).—Contrary to the conclusions of De Kruffy, the author found *Azotobacter chroococcum* in all but one of a series of Java soils, and in this the chlorin content was 3.86 per cent, indicating sufficient sodium chlorid to kill the bacteria. *Bacillus radiobacter* was also found to be generally present in Java soils.

Methods in soil bacteriology.—VI, Ammonification in soil and in solution, F. LÖHNIS and H. H. GREEN (*Centbl. Bakt. [etc.]*, 2. Abt., 37 (1913), No. 22-25, pp. 534-562; *abs. in Jour. Chem. Soc. [London]*, 104 (1913), No. 609, I, pp. 797, 798; *Chem. Abs.*, 7 (1913), No. 19, pp. 3380, 3381).—This is a critical study of the factors affecting ammonification and nitrification of blood meal, flesh meal, and horn meal under laboratory conditions. It is considered that in determining the relative value of laboratory tests in soil and solution media the specific mode of application of methods must be clearly defined, since widely varying results may be obtained in both cases according to variation in the experimental conditions. "The most significant cause of variation appears to be that of aeration."

Ammonification, as well as nitrification, proceeded much more rapidly under aerobic than under anaerobic conditions. It is believed that aerobic conditions especially favor the later stages of breakdown resulting in the formation of ammonia itself. Under conditions of insufficient aeration, increasing the quantity of nitrogenous material used retarded the ammonification, but with adequate aeration it had little influence. In general smaller quantities of material experienced more complete ammonification although the chemical nature of the material used seemed to be the dominant factor. The duration of the experiment affected the apparent extent of ammonification, the rate of ammonification being in general greatest during the first ten days in both soil and solution. The three materials used showed very different rates of decomposition.

In solution tests the losses of ammonia by evaporation were highest and the relative extent of ammonia assimilation lowest with the larger quantities of material. In these tests the use of magnesium hydrogen phosphate effected marked conservation of ammonia only in the longer periods of decomposition. However, the ammonia not lost through evaporation was assimilated by the

bacteria. In solution tests the depth of liquid was found to be the chief factor in controlling aeration, while in soil tests the depth of soil layer and the degree of moisture exercised relatively little effect within comparatively wide limits. However, where the depth of the soil layer interferes with aeration marked differences are said to appear.

In solution nitrification was not observed in the presence of the three materials used, while in soil tests with liberal aeration and not too large an excess of ammonia it kept pace with ammonification. There was accumulation of ammonia with the larger quantities of material but not with the smaller. In the longer periods the ammonia accumulated during the earlier stages was partly nitrified and partly lost by evaporation. With inadequate aeration there was no formation of nitrate.

The metabolism of flesh meal proceeded almost as fast in solution as in soil, while horn meal and blood meal decomposed much more rapidly in soil.

Nitrate and nitrite assimilation, O. BAUDISCH (*Ztschr. Angew. Chem.*, 26 (1913), No. 83, *Aufsatzteil*, pp. 612, 613).—The author attempts to show in this article that the nitroxyl group plays an important rôle in nitrogen changes in green plants, and discusses the ways in which this is done.

Studies on the decomposition of cellulose in manures and soils, C. MÜTTERLEIN (*Studien über die Zersetzung der Zellulose im Dünger und Boden*. [Inaug. Diss.] Leipzig, 1913; *abs. in Centbl. Bakt. [etc.]*, 2. Abt., 39 (1913), No. 4-7, pp. 167-169).—The work of other investigators on this subject is reviewed and a series of experiments with different culture media and various inoculating materials is reported.

The effect of toluol and CS_2 upon the micro-flora and fauna of the soil, P. L. GAINES (*Missouri Bot. Gard. Ann. Rpt.*, 23 (1912), pp. 147-169; *abs. in Centbl. Bakt. [etc.]*, 2. Abt., 39 (1913), No. 4-7, p. 158).—The results of the investigations reported in this article are summarized as follows:

"(1) Small quantities of CS_2 , toluol, and chloroform, such as have been used practically and experimentally, when applied to the soils studied exert a stimulative rather than a diminishing effect upon the total number of bacteria present.

"(2) An application of such quantities of CS_2 and toluol does not have an appreciable effect upon the number of types of protozoa present in such soils as have been studied.

"(3) A very marked increase in yield may be noted following such an application when no evident change occurs in total number of bacteria present.

"(4) In the light of the recent work of Koch, Egorov, Goodsey, Fred, and others, with results presented in this paper, the theory advanced by Russell and Hutchinson to account for the increased yield following the application of such chemicals appears not tenable for general application."

The influence of fertilization on the condition of the soil and its fitness for certain crops, A. MAUSBERG (*Landw. Jahrb.*, 45 (1913), No. 1, pp. 29-101).—Studies conducted for 18 years on the relations between the properties of a soil and its fertilization and productiveness are reported, and methods of physical, mechanical, and chemical analyses, and of eliminating errors are reviewed. The tested soil was originally a medium heavy, deep loam, mostly fine grained, with a hygroscopicity of about 2.98 per cent and an absorption coefficient for ammonia of 72.5 mg. It contained relatively small quantities of plant food, although needing only moderate potash and very little phosphoric acid fertilization.

In experiments made to determine the influence of varied fertilization on the physical, mechanical, chemical, and biological properties, it was found that soil

not fertilized for a long period became rather dense in structure, suffered during drought, became saturated and sticky during wet weather, dried very slowly, and showed little useful bacterial activity. Its alkalinity was also low.

Continuous treatment with either sodium nitrate or kainit produced a dense, crusted structure and reduced the basicity and the useful bacterial action. Continued ammonium sulphate treatment had a detrimental effect on the soil reaction and bacterial activity. Continuous lime treatment produced all the characteristics of high fertility, with the exception of impoverishment in potash, as did also the magnesia treatment to a little less degree.

Complete fertilization without lime produced results in no way inferior to those produced by continuous lime treatment. There was a most marked exhaustion of potash with complete fertilization except potash. Mixed fertilization with stable manure, mineral phosphates, and potash produced only a medium physical structure and somewhat better bacterial activity, but reduced the alkalinity.

Rye, oats, peas, potatoes, and sugar beets were grown on differently fertilized plats. Winter rye appeared to thrive on all the soils regardless of fertilization, little difference being observed on different plats. Oats required an excess of easily assimilable nitrogen, which it preferred as sodium nitrate. Aside from nitrogen the oats required sufficient potash.

For a good yield of peas, both potash and lime were necessary, the absence of either causing the same shortage in yield as the absence of both. Potatoes thrived best with plenty of potash, and preferred ammonium sulphate to sodium nitrate as a source of nitrogen. A change in soil reaction affected them but little, as complete fertilization without lime and with magnesia did not decrease the yield. The highest yield of potatoes was obtained with mixed fertilization of stable manure, mineral potash, and phosphate fertilizers in spite of the low alkalinity of the soil.

For a good yield, sugar beets required each of (1) easily assimilable nitrogen, (2) sufficient potash, (3) high alkalinity in connection with a satisfactory soil structure, and the yield decreased in proportion to the deficiency of any of these three. The beets stood in direct contrast with potatoes, since, in spite of the presence of magnesia, they were badly affected by a deficiency of lime and preferred sodium nitrate to ammonium sulphate as a source of nitrogen.

Fertilization had a more lasting influence on the starch content of potatoes than on the sugar content of beets, but although both depended largely on potash, an excess of this reduced the quality of the potatoes and improved that of the beets. Phosphoric acid had little effect on the yield of either, but ammonium sulphate increased the carbohydrate formation in both.

Experiences with commercial fertilizers and manure, W. LONERGAN (*Ann. Rpt. Nebr. Corn Improvers' Assoc.*, 4 (1913), pp. 85, 86).—Experiments with manure and fertilizers on a good clay upland soil in Nebraska led to the conclusion that the use of manure was superior to all other treatments, and that there was little or no advantage in the use of commercial fertilizers on such soils.

Fertilizer experiments on peaty meadows in Hungary, J. GYÁRFÁS (*Köztelek [Budapest]*, 23 (1913), No. 43, pp. 1553, 1554; *abs. in Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 8, pp. 1194, 1195).—Cooperative experiments in different parts of Hungary showed in general that the use of a fertilizer containing phosphoric acid and potash gave highly remunerative results.

The results of experience with fertilizers during the last twenty-five years, LEMMERMANN (*Illus. Landw. Ztg.*, 33 (1913), No. 48, pp. 450, 451).—This is a brief review of German experience and shows that the free use of fertilizers

has been a large factor in increasing agricultural production in that country. In fact, 50 per cent of the increase, which has been very pronounced, is attributed to the rational use of fertilizers.

Bone products and manures, T. LAMBERT (*London, 1913, 2. rev. ed., pp. VII+167, figs. 17*).—This is a second revised edition of this work (E. S. R., 13, p. 634).

The solubility of soil constituents, H. FISCHER (*Internat. Mitt. Bodenk., 3 (1913), No. 4, pp. 331-337, fig. 1*).—In a comparison of the solubility of phonolite and biotite in water saturated with carbon dioxid according to the Mitscherlich method it was found that the potash of the latter was less soluble than that of the former. This, however, is not in accord with results of crop tests by other investigators which showed that the potash of biotite is more readily assimilated by oats than that of phonolite. Methods of rendering the potash of phonolite more assimilable by plants are briefly discussed.

Comparative manuring experiments with crushed phonolite and 40 per cent potash salts, F. WAGNER (*Prakt. Bl. Pflanzenbau u. Schutz, n. ser., 11 (1913), Nos. 4, pp. 52-53; 5, pp. 67-70; 6, pp. 77-82, fig. 1; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 4 (1913), No. 10, pp. 1534, 1535*).—Ground phonolite was compared with 40 per cent potash salt on hops grown on soils poor in potash. The phonolite was used in connection with a basal fertilizer of ammonium sulphate, Thomas slag, and lime, but the results from its use were in no way comparable with those obtained with the potash salt.

The possibility of replacing Stassfurt potash salts by finely ground phonolite, leucite, etc., LEMMERMANN (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 4 (1913), No. 10, pp. 1483-1495*).—Experiments with various natural silicates of potash are reviewed.

It is shown that the fertilizing effect of these is variable, but generally low. They are not comparable with potash salts. Various processes which have been proposed for the improvement of their assimilability are noted, but it is held that none of them offers a practical substitute for the German potash salts.

Influence of the condition of the soil on the utilization of different phosphates, H. R. CHRISTENSEN (*Fühling's Landw. Ztg., 62 (1913), No. 11, pp. 392-405*).—Experiments are reported which were conducted to determine the relative values of superphosphate, Thomas slag, bone meal, and Algerian phosphate fertilizers under varying conditions of cultivated and meadow soils, the variable factors being the power of the soils to set free acids, especially phosphoric acid, the moisture content, and the basicity.

On cultivated soils the effects of the superphosphate and Thomas slag were uniformly good, and both were utilized in practically the same quantities in acid and basic soils, the Thomas slag being utilized slightly the more. Using superphosphate as a standard, the results with bone meal and Algerian phosphate were poor. With a single exception it was found that the utilization of the phosphoric acid of bone meal as compared with that of superphosphate was very small in basic soils, while in nonbasic and acid soils the two were utilized to about the same extent. No definite relations were found to exist between the acid separating powers of cultivated soils and the utilization of the four phosphates.

In meadow soils superphosphate was utilized to a somewhat greater extent than Thomas slag, the utilization of Thomas slag being greatest in the basic soils. Bone meal, with one exception, was not utilized so well as superphosphate. Better utilization of bone meal was found on moist than on dry soils with greater acid separating powers. The effect of basicity on bone meal was not so marked as in the cultivated soils.

It is concluded that the utilization of slowly soluble phosphates is largely regulated by the amount of water present in the soil during the growing season, being greater in moist than in dry soil, and also that bone meal can not be satisfactorily used on basic soils. Although little tested, Algerian phosphate is classed with bone meal.

Origin of the hard rock phosphates of Florida, E. H. SELLARDS (*Fla. Geol. Survey Ann. Rpt.*, 5 (1912), pp. 23-80, pls. 10).—The nature and location of the hard rock phosphate deposits are described and theories of their origin are discussed.

As regards the origin of these deposits the author holds "that the matrix of the hard rock phosphate deposits is the residue of the formations that have disintegrated in situ, and that the phosphate itself is derived from the phosphate originally widely disseminated through these formations, circulating waters being the agency by which the phosphate has been carried to its present location."

An extensive bibliography of the subject is given.

Production of phosphate rock in Florida during 1912, E. H. SELLARDS (*Fla. Geol. Survey Ann. Rpt.*, 5 (1912), pp. 291-294).—The statistics of production of different kinds of phosphate rock in Florida in 1912 and several preceding years are summarized. A list of phosphate manufacturing companies operating in the State during that year is also given.

Consumption of superphosphates in Hungary, B. KOVÁCSY (*Közeleik [Budapest]*, 23 (1913), No. 42, pp. 1532, 1533; *abs. in Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intcl. and Plant Diseases*, 4 (1913), No. 8, p. 1201).—The data reported show a marked increase in the consumption of commercial fertilizers, especially superphosphates, which constitute 80 per cent of the total amount of chemical fertilizers employed. The use of superphosphate varies from $\frac{1}{2}$ to 72 lbs. per acre of cultivated area in different parts of the country.

Calcium pyrophosphate, A. MENOZZI (*Indus. Chim.*, 13 (1913), pp. 261, 262; *abs. in Jour. Soc. Chem. Indus.*, 32 (1913), No. 19, p. 953).—When phosphorite was heated with moist sulphur dioxide in presence of air there was obtained a fine white powder consisting of calcium sulphate and pyrophosphate. The properties of this product are described and it is stated that it is as effective as a fertilizer as superphosphate or basic slag. It is not proposed, however, that it be used as a fertilizer in this form, but that it be converted into superphosphate by treatment with sulphuric acid. By this treatment a product is obtained which is of lower acidity than ordinary superphosphate.

The degree of fineness of fertilizer lime, D. MEYER (*Illus. Landw. Ztg.*, 33 (1913), No. 84, p. 755).—The author concludes from the examination of a large number of samples of agricultural lime that not less than 70 per cent of such lime should pass a sieve with meshes 0.2 mm. in diameter, and that not more than 75 per cent of the particles passing a 0.5 mm. sieve should be larger than 0.2 mm. in diameter. The particles larger than 0.5 mm. but smaller than 1 mm. should not exceed 25 to 50 per cent.

Evolution of sulphur in the soil: A study of its oxidation, C. BRIOUX and M. GUERRET (*Compt. Rend. Acad. Sci. [Paris]*, 156 (1913), No. 19, pp. 1476-1479; *Ann. Sci. Agron.*, 4. ser., 2 (1913), II, No. 4, pp. 385-396; *abs. in Rev. Sci. [Paris]*, 51 (1913), I, No. 21, p. 668; *Jour. Chem. Soc. [London]*, 104 (1913), No. 609, I, p. 811; *Chem. Zentbl.*, 1913, II, No. 4, p. 379).—The author studied the influence of the character of the soil and of certain carbohydrates on the oxidation of sulphur.

Sugar and starch appreciably retarded oxidation, while peptone and other nitrogenous substances favored it to such an extent that 82 per cent of the sulphur was oxidized in 30 days. The oxidation of the sulphur was due to

a very complicated bacteriological process probably involving a number of different kinds of bacteria. The addition of calcium carbonate greatly accelerated oxidation, but sterilization almost entirely prevented it.

The composition of sediments from the Potomac and Shenandoah rivers, J. G. SMITH and W. H. FRY (*Jour. Indus. and Engin. Chem.*, 5 1913), No. 12, pp. 1009-1011).—Mineralogical and chemical analyses of a large number of samples of the sediments are reported.

The mineralogical character of the sediments of the two rivers was decidedly different. The chemical analyses showed no definite relation between the composition and the amount of sediment carried by the streams when the samples were taken, and no uniformity of chemical composition of the sediments as a whole. It was found, however, that the fine particles were comparatively high in potash, phosphoric acid, lime, organic matter, etc.

The production and consumption of chemical fertilizers in the world (*Production et Consommation des Engrais Chimiques dans le Monde. Rome: Inst. Internat. Agr.*, 1913, pp. VI+134, pls. 6; rev. in *Jour. Soc. Chem. Indus.*, 32 (1913), No. 15, pp. 801, 802).—This report gives detailed statistics as far as they are available of the production of raw materials supplying phosphoric acid, potash, and nitrogen in fertilizers, and of the consumption of commercial fertilizers in 62 different countries, with a statement of the sources from which the information was drawn.

It is estimated that the value of the fertilizers at present consumed in the world exceeds \$400,000,000. The average consumption is stated to exceed 178 lbs. per acre of cultivated area in Belgium, Mauritius, and Luxemburg, and to vary from 89 to 178 lbs. in Germany and the Netherlands; from 45 to 89 lbs. in Denmark, United States (southern States), France, England, Australia, Italy, and Switzerland; from 9 to 45 lbs. in Austria, Hungary, Spain, United States (northeast), Norway, Dutch East Indies, Portugal, and Sweden. "All the remaining countries consume less than 9 lbs. per acre or an unknown amount." As a rule the latest figures given are those for 1911.

Commercial fertilizers and their importance in the world's industry, K. KUBIERSCHKY (*Ztschr. Angew. Chem.*, 26 (1913), No. 97, Aufsatzteil, pp. 721-729, fig. 1).—A historical and general review of this subject, based in part upon the report noted above.

AGRICULTURAL BOTANY.

Department of botanical research, D. T. MACDOUGAL (*Carnegie Inst. Washington Year Book*, 11 (1912), pp. 49-76, pl. 1).—An outline is given of the work carried on by the members attached to the laboratories maintained by this institution and of investigations carried on under its auspices. These include studies on phyto-chemistry, the water relations of plants, and the environic reactions of organisms. Among some of the lines of work more or less briefly reported upon are the alterations in woody tissues and bacterial action in Salton water, the behavior of micro-organisms in brines, the floral elements of the Salton region, physical and botanical features of Sudanese and Libyan deserts, botanical features of the Algerian Sahara (*E. S. R.*, 29, p. 626), depth of water table as a factor limiting distribution of trees, the soil moisture evaporation index and its relation to vegetation, water relations of plants, physical relations of roots to soil factors, structural relations in xenoparasitism (*E. S. R.*, 28, p. 332), the determination of leaf temperatures, and chemical effects of radiant energy in plant processes.

A bibliography is appended.

Origin of species by mutation, A. W. SUTTON (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, pp. 158, 159; abs. in Bot. Centbl., 123 (1913), No. 10, p. 247*).—The author states that observations extending over 40 years have convinced him that, while permanent variations may appear and retain their distinctive characteristics when isolated and grown (some being, however, only fluctuating variations tending soon to lose their identity), there is nothing approaching a really new species which has arisen by so-called mutation in the plants observed.

On the principle of the coalescence of living plasmas and the origin of races and species, A. GAUTIER (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, pp. 79-90, fig. 1; abs. in Bot. Centbl., 123 (1913), No. 9, pp. 214, 215*).—The author sums up the results of studies extending over some years.

Observations on cross-fertilization, grafting, etc., are claimed to show that somatic plasma possesses a property similar to that of the germ plasma, namely the power to transmit to the bud and to the ovary of the plant a modification which is immediately apparent and which in some cases may be transmitted to the offspring. The step from one race or species to another corresponds to a modification of the chemical principles essential to the race or species, this chemical differentiation being the sign of a corresponding variation in the protoplasm, resulting in a sudden alteration of function, of product, and of growth as regards external form. The coalescence of vegetable or somatic plasma may be as effective as that of germ plasma in the production of new races, uniting species and even genera. The stimulus may originate from insects, microbes, etc., acting directly or indirectly toward these results.

The author concludes that it is by the union or symbiosis of plasmas, sexual or somatic, resulting from fertilization, grafting, or parasitic or traumatic action, that, either modifying the relation of certain ferments or preventing their formation, gives rise to those abrupt changes by which new races or species are produced; and that the variations of the individuals and of the races thus formed do not transgress the limits beyond which analogy with anatomical structures or with specific chemical principles no longer exists.

Studies of natural and artificial parthenogenesis in the genus Nicotiana, R. WELLINGTON (*Amer. Nat., 47 (1913), No. 557, pp. 279-306; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 4 (1913), No. 7, p. 1039*).—The author reports several hundred attempts with stimuli caused by foreign pollen, mutilations, fumigation, and infections on numerous species and varieties of *Nicotiana* to produce parthenogenesis in the seed without success, and concludes that it probably does not occur in the forms tested.

An extensive bibliography is given.

Periodicity of specific characters, P. VUILLEMIN (*Bul. Soc. Sci. Nancy, 3. ser., 13 (1913), No. 3, pp. 179-218, figs. 13*).—The author concludes an account of studies made by him on morphology in different stages, as noted in a number of plants, by stating that various forms of polymorphic plants or organs thereof may appear in a determinate order, which fact requires in such cases that these successive characters be employed to give a complete definition of the species. It is admitted that this habitual periodicity may be interfered with by external agencies, but it is still held that those teratological characters which exhibit periodic polymorphism are to be regarded as specific.

Biology and radio-activity, G. PETIT (*Rec. Méd. Vét., 90 (1913), No. 17, pp. 584-590, figs. 2*).—Besides brief mention of some work by other investigators, an account is given of recent studies by the author regarding the influence of radio-activity on rye grass, wheat, and corn. Some experiments on the last named showed a striking acceleration of growth, the results in general con-

firming previous conclusions reached by the author in connection with Ancelin (E. S. R., 29, p. 326).

The determination of the rays concerned in chlorophyll synthesis, P. A. DANGEARD (*Botaniste*, 12. ser., 1912, pp. XXI-XXVI; abs. in *Ann. Bot. [Rome]*, 11 (1913), No. 3, pp. 501, 502).—The author investigated further (E. S. R., 25, p. 221) the influence on chlorophyll synthesis of the different portions of the spectrum obtained from a Nernst lamp, employing in these later experiments a quartz prism.

It is stated that there exists a direct relation between the growth of a green alga and the absorption of radiations by its contained chlorophyll, the maximum effect appearing between the lines of wave length 660 to 670. The rate of absorption of chlorophyll in solutions by an alga or its rate of vegetative development therein corresponds closely to the concentration employed. Notwithstanding considerable absorption of xanthophyll below line 490, the energy absorbed is insufficient to cause chlorophyll synthesis in that part of the spectrum. It is also claimed that blue and violet rays do not appear to have any important influence on chlorophyll synthesis.

New observations on chlorophyll assimilation and reply to recent criticisms, P. A. DANGEARD (*Bul. Soc. Bot. France*, 60 (1913), No. 2-3, pp. 166-175).—Referring to results obtained from work above noted and calling attention to observations of other investigators, the author replies to certain objections offered to his previous conclusions.

Two years' experiments with static electricity as related to the growth of cultivated plants, P. TRNKA (*Zemědělský Arch. (Arch. Bodenkult. Böhmen)*, 4 (1913), No. 1; abs. in *Bot. Centbl.*, 123 (1913), No. 6, p. 138).—The author gives an account of experiments in which insulated wire nets stretched at a height of 4 or 5 meters above 36 hectares of growing beets were subjected to an electric current of from 50,000 to 70,000 volts and 0.7 to 0.8 milliamperes for 1,468 hours in 223 days of 1911, and 2,000 hours in 299 days of 1912.

The production of the field was sensibly increased, but the question as to the profitableness of the treatment was not fully settled. Differences in chemical composition were noted, both during the growing period and after maturity. These increased yields appear not to be explainable as due to differences in transpiration, stimulation, or assimilation processes, and this fact leads to the supposition that the electricity exerts its direct influence upon the soil rather than upon the plant. This mode of culture is thought to be better suited to plants having large assimilation surfaces.

On the growth of plants in partially sterilized soils, E. J. RUSSELL and F. R. PETHERBRIDGE (*Jour. Agr. Sci. [England]*, 5 (1913), No. 3, pp. 248-287, pls. 4, fig. 1).—For a number of years experiments have been in progress in growing plants in partially sterilized soils, and some of the observed facts are placed on record. The partial sterilization was effected by the use of toluene and by heating to 55 and 100° C.

The germination of seeds planted in these soils was sometimes hastened, at other times retarded. Retardation was almost always produced in soils heated to 100° or treated with toluene, while acceleration often followed the planting of seeds in soils heated to 55°. The retarding effect was generally more pronounced in moist than in dry soils and in rich than in poor ones.

In the seedling stages the plants produced on partially sterilized soils were sometimes indistinguishable from those on untreated soils. Seedling tomatoes grown on heated soils in comparison with those grown on untreated ones had smaller roots and smaller cotyledons of a darker green color, frequently showing some purple. The effect on the seedlings was most pronounced during the dull days of winter, and this has a practical application in the use of partial

sterilization for the growth of plants under glass. Later marked differences were shown, the purple color disappeared, and the plants began to show remarkable growth.

Sometimes soils treated with toluene behaved like those heated to 55°, but on rich soils early development was retarded. Other volatile antiseptics were found to behave like toluene.

Comparing partially sterilized with untreated soils, the authors found that there was generally a retardation in germination, although sometimes partial acceleration occurred. An acceleration in growth followed up to the time of the appearance of the third or fourth leaves, but sometimes a marked retardation was noticed, especially in rich soils heated to 100°. Where this retardation occurred it was accompanied by a very dark green leaf color and either the formation of a purple pigment or a tendency for the leaves to curl toward the underside. Later the purple color disappeared, the curling ceased, and rapid growth took place. The subsequent growth was finally proportional to the amount of food present. Plants grown on soils heated to 100° showed a remarkable development of fibrous roots, and, in comparison with those on untreated soils, had larger leaves of a deeper green color, stouter stems, usually shorter internodes, flowered earlier and more abundantly, and contained a higher percentage of nitrogen and sometimes of phosphoric acid in their dry matter. Plants grown on soils heated to 55° or treated with volatile antiseptics showed fewer of these effects.

Considering the chemical differences in the soils, it is stated that partially sterilized soils are characterized by an accumulation of ammonia, while untreated soils contain practically no ammonia. Soils heated to 100° are characterized by the presence of decomposition products, some of which possess characteristic colors and odors.

The authors present the data upon which their paper is based and give an extended discussion of their observations.

Some organic constituents of the culture solution and the mycelium of molds from soil, M. X. SULLIVAN (*Abstr. in Science, n. ser.*, 38 (1913), No. 984, p. 678).—An examination was made of the dried mycelium of mixed mold cultures from soil, of *Penicillium glaucum* grown on Raulin's solution, and of the filtered solution after a mold growth to determine the various organic constituents.

In the mixed molds a large number of organic substances were found, many of which were subsequently recognized in *P. glaucum*. In the alcoholic soda extract of *P. glaucum* the author found oleic and palmitic acids, a fatty acid melting at 54° C., a fatty acid which appears to be elaidic acid, hypoxanthin, guanine and adenine, histidine, thymine, and chlorin. In the direct alcohol extract, mannite, cholesterol bodies, hypoxanthin, and cerebrosides were found. Guanidine was determined from mold grown on Raulin's solution, to which peptone in small quantity was added. In the culture solution after a number of weeks' growth were found fatty acids, purine bases, a small quantity of a histidine-like body, pentose sugar, unidentified aldehydes, etc. Many of these compounds have been found in soil, and the conclusion is drawn that micro-organisms, such as yeast, bacteria, and molds, play an important part in their formation.

Polyatomic alcohols as sources of carbon for molds, R. E. NEIDIG (*Abstr. in Science, n. ser.*, 38 (1913), No. 984, p. 675).—A comparison was made of methyl alcohol, glycol, glycerol, erythrite, adonite, mannite, dulcitol, and sorbitol to determine their availability as sources of carbon for 8 species of molds representing 4 genera.

It was found that methyl alcohol produced no growth, glycol induced germination only, glycerol produced strong cultures, erythrite could be used by the

majority of molds, and adonite by only a few. All 3 of the hexatomic alcohols may be considered good sources of carbon.

The influence of starch, peptone, and sugars on the toxicity of various nitrates to *Monilia sitophila*, O. KUNKEL (*Bul. Torrey Bot. Club*, 40 (1913), No. 11, pp. 635-639).—Studies were made to determine whether or not the toxicity of various salts to *M. sitophila* is influenced by sugars, starch, or peptones.

The results show beyond question that the concentration at which the various inorganic salts are toxic depends on the kind of organic substance contained in the media to which those salts are added. The degree of toxicity of the nitrates of barium, aluminum, iron, and urea depends on the organic substance contained in the media in which these salts are offered. Barium nitrate is more toxic in peptone than in starch media, while iron and aluminum nitrates are more toxic in starch than in peptone media. The toxicity of iron nitrate is approximately the same in starch as in other carbohydrates, but it is much less toxic in peptone media. Urea nitrate was found to be four times more toxic in starch than in peptone media.

On the effect of chloroform on the respiratory exchanges of leaves, D. THODAY (*Ann. Bot. [London]*, 27 (1913), No. 108, pp. 697-717, figs. 15).—The author made a study to determine whether a close quantitative relation exists between the evolution of carbon dioxide and the absorption of oxygen under the influence of stimulating agencies. Sunflower, garden nasturtium, cherry laurel, etc., were subjected to the effect of chloroform, and in all the leaves examined treatment with a small dose of chloroform resulted in a stimulation of the respiration, and the absorption of oxygen and production of carbon dioxide apparently remained coordinated. When the concentration of chloroform vapor was large enough to bring about visible disorganization, the production of carbon dioxide was diminished and the absorption of oxygen was no longer closely correlated with the production of carbon dioxide.

In leaves of the nasturtium (*Tropæolum majus*), which contain no tannin, the absorption of oxygen was depressed still more than the production of carbon dioxide. In leaves of other species containing tannin the absorption of oxygen was very rapid for a short time, and though falling quickly, remained at a higher level than the production of carbon dioxide.

Tannin and starch in the assimilating organs of Leguminosæ, H. KLENKE (*Ueber das Vorkommen von Gerbstoff und Stärke in den Assimilationsorganen der Leguminosen. Diss., Göttingen, 1912, pp. 83; abs. in Bot. Centbl.*, 122 (1913), No. 18, pp. 446, 447).—As a result of studies on 208 different species of Leguminosæ, the author concludes that tannin is usually more plentiful in leaves or parts more exposed to sunshine, especially in summer, reaching a maximum for the leaves in the vascular bundles and the leaf edges. The stomatal cells vary in this respect less than do neighboring cells. The concentration of tannin is said, however, to be greater in the petiole and shoot than in the leaf. Cells without tannin have more starch than do those containing tannin.

The castor bean plant and laboratory air, E. M. HARVEY (*Bot. Gaz.*, 56 (1913), No. 5, pp. 439-442).—The author reports having found potted seedlings of castor bean, grown under ordinary greenhouse conditions until they had developed from 5 to 7 leaves, were unusually susceptible to gas impurities. One part of ethylene to 50,000 of air was found to result in proliferation and exudation at leaf scars. Leaf fall took place in concentrations as low as 1 part of ethylene to 500,000 of air, or even to 1,000,000 parts of air. A drooping of the youngest well-developed leaves could be taken as an index of the occurrence of still lower concentrations of the gas.

Osmotic pressure in potatoes, M. A. BRANNON (*Bot. Gaz.*, 56 (1913), No. 5, pp. 433-438, figs. 4).—This article has been previously noted (*E. S. R.*, 29, p. 133).

Imbibition studies on seeds of *Avena sativa*, F. PLATE (*Atti R. Accad. Lincei, Rend. Cl. Sci. Fis., Mat. e Nat.*, 5. ser., 22 (1913), II, No. 3, pp. 133-140).—Summing up studies carried out with beans in solutions of several acids, bases, and salts, the author claims that no exclusive part in imbibition is played by either cations or anions in this connection, and that most of these chemical agents promote germination even in high concentrations.

Influence of moisture relations on species of *Pinus*, B. HERGT (*Mitt. Thüring. Bot. Ver.*, 30 (1913), pp. 129, 130; *abs. in Bot. Centbl.*, 123 (1913), No. 9, p. 220).—The author notes a striking limitation in growth, during the dry year, 1911, of needles of *P. sylvestris* and *P. nigra* as compared with the 1912 growth on the same branches.

Defoliation: Its effects upon the growth and structure of the wood of *Larix*, A. G. HARPER (*Ann. Bot. [London]*, 27 (1913), No. 108, pp. 621-642, pls. 2, figs. 2).—A study has been made of trunks of larch trees that have been recently defoliated by the larvæ of the larch sawfly.

It was found that premature defoliation resulted in a greater or less degree of starvation, which was shown by the quantity of the growth and the structure of the wood formed. If starvation is severe, growth may cease over certain parts of the cambium mantle, while other regions are still active. The investigations showed that in larch trees killed by defoliation, growth ceased entirely at the base of the tree a year or more before the tree died. The first visible effects of defoliation in the structure of the wood is said to be the reduction of the proper thickening of the walls and cells of part or all of the zone of autumn wood, without much decrease in the breadth of the whole ring. The outermost cells of the autumn wood may have their walls unthickened on account of the lack of food supply at this period of the year. Abnormally formed resin ducts were found and they are considered possibly a pathological effect of starvation.

Root secretions of plants, E. A. MITSCHERLICH (*Landw. Vers. Stat.*, 81 (1913), No. 3-6, pp. 469-474).—This continues a somewhat controversial discussion by the author (*E. S. R.*, 28, p. 721), Rodewald (*E. S. R.*, 28, p. 722), and Pfeiffer et al. (*E. S. R.*, 28, p. 518), regarding the existence and expression of a law of minimum.

FIELD CROPS.

[Test work with forage and field crops], M. CALVINO (*Estac. Agr. Cent. [Mexico] Bol.* 66, 1912, pp. 3-23, 41-48, 67-72, pls. 22).—Trials in the production of forage crops are here reported.

Oats and white mustard grown together produced at the rate of 64,660 kg. of green fodder per hectare (28.77 tons per acre) in 3 months, and Thousand-headed kale yielded at the rate of 68,000 kg. in 5 months. *Dactylis glomerata*, *Phleum pratense*, and *Bromus inermis* made satisfactory growth, *Dactylis* being especially luxuriant and reaching 1½ meters at the flowering stage. Notes are given on variety tests of turnips and the value of turnips and oats sown together for forage. Tests of *Trigonella fœnum-græcum*, *Medicago arborea*, *Hedysarum coronarium*, and *Onobrychis sativa* are also mentioned.

Variety tests with potatoes produced yields ranging from 2,782 to 13,000 kg. per hectare. Whole tubers gave much better results as seed than cut tubers. Directions for seed selection of potatoes are given. Notes on the value, cultivation, harvest, and uses of buckwheat are given, as are also variety tests in which the yields ranged from 1,800 to 2,800 kg. per hectare.

[Crop experiments for 1912], E. LÓPEZ (*Bol. Ofic. Sec. Agr. Cuba*, 12 (1912), No. 6, pp. 673-681).—This report summarizes the experimental work done during the year with alfalfa, malanga (*Arum*), cassava, plantain, sugar cane, tobacco, peanuts, sweet potatoes, and maize.

[Crop experiments] (*Rev. Indus. y Agr. Tucumán*, 3 (1913), No. 10-11, pp. 477-487).—This paper reports results of variety and cultural tests of maize, rice, cowpeas, beggar weed, peanuts, and cotton.

Cooperative fertilizer and variety tests in Malmöhus County, 1912, L. FORSBERG (*Malmö, Ljans Hushåll. Sällsk. Körtlsskr.*, 1912, No. 4, pp. 330-1007).—This report covers 83 cooperative fertilizer trials conducted at 59 different farms with barley and oats, mixed cereals, sugar beets, other root crops, potatoes, and meadows. Thirteen lime experiments were also conducted as well as variety tests with winter wheat, barley and oats, potatoes, and root crops.

The results of 4 years' work indicated that 37.5 per cent of the sandy soils experimented with were alkaline, 20 per cent neutral, and 42.5 per cent acid, while the corresponding figures for clay soils were 52.5, 21.5, and 26 per cent.

Report on hemp and tobacco in Italy and Holland, KLUFTINGER ET AL. (*Ber. Landw. Reichsanst. Innern*, 1913, No. 26, pp. VIII+153, pl. 1, figs. 4).—This publication contains accounts of the cultivation and manufacture of hemp in Italy and of tobacco in Italy, Java, and Sumatra.

Report of the work of the moorland experiment department of the agricultural chemical experiment station at Dublany in 1912, E. ANSON (*Ztschr. Moorkultur u. Torferwert.*, 11 (1913), No. 2, pp. 50-68, figs. 4).—In testing the value of moorland for the production of hay, over 20 varieties of cultivated grasses were sown singly and in various mixtures without fertilizers. The yields of the pure cultures ranged from 34.68 to 84 quintals per hectare and the mixtures from 32.5 to 68.85 quintals (from 1.4 to 3 tons per acre).

Potatoes yielded as high as 294.5 quintals per hectare with 400 kg. of 40 per cent potash salt and 100 loads of barnyard manure. The use of 400 kg. each of 40 per cent potash salts and Thomas slag per hectare produced 355.66 quintals of potatoes, as against 242.3 quintals with an application of 200 kg. of flowers of sulphur.

Trials of sugar beets, summer and winter rye, hemp, vetch, seradella, lupines, summer and winter wheat, barley, flax, sunflowers, and oats are also reported.

Annual report of the Bankipur Agricultural Experimental Station, 1911-12, G. SHERRARD (*Ann. Rpt. Bankipur Agr. Expt. Sta. [India]*, 1911-12, pp. 12).—This report gives tabulated results of manurial experiments, with cost data, variety tests, and seeding and plowing experiments with rice and sugar cane. The profits were greatest when cow manure and castor cake were used.

Notes on forage in Java and India, C. V. PIPER (*Philippine Agr. Rev. [English Ed.]*, 5 (1912), No. 8, pp. 428-431, pl. 1).—This paper contains brief notes on *Paspalum conjugatum*, *Panicum numidianum*, *Polytrias præmorsa*, *Imperata exaltata*, *Paspalum marginatum*, *Andropogon annulatus*, *Pennisetum cenchroides*, and *Eleusine coracana* as native forage plants in these countries.

Magney (Cantala) and sisal in the Philippines, M. M. SALEEBY (*Philippine Agr. Rev. [English Ed.]*, 6 (1913), No. 4, pp. 183-188, pls. 4).—This article discusses the history, introduction, methods of cultivation, and preparation of the fiber of these two plants in the Philippines.

Tests of raw phosphates, P. E. GALZEW and I. W. JAKUSCHKIN (*Izv. Moskov. Selsk. Khoz. Inst. [Ann. Inst. Agron. Moscou]*, 19 (1913), No. 1, pp. 193-204, figs. 2).—These phosphates were derived from different geological formations, viz, golt, turon, and Rjasen, and showed varying values when applied to yellow lupines and buckwheat.

On variation in rust resistance of different forms of pure lines of spring wheat, spring barley, and oats, N. LITWINOW (*Trudy Būro Prikl. Bot. (Bul. Angew. Bot.)*, 5 (1912), No. 10, pp. 347-423).—This article gives data in tabular form, obtained from observations during 1910 and 1911, of 186 forms of pure lines of spring wheat, 49 forms of barley, and 50 forms of oats in regard to their behavior toward various rust forms (*Puccinia graminis*, *P. simplex*, *P. coronifera*, and *P. triticea*), including descriptions of leaf surface and dates of sending up shoots of each variety.

The laying down of permanent pastures and meadows, H. LANG (*Landw. Hefte*, 1913, No. 12, pp. 32).—This article describes the most important grasses, clovers, and other plants used in pastures and meadows, and gives directions for the selection of soils, varieties, and mixtures for certain purposes. Methods of preparing the seed bed, seeding, cover crops to use, and the care of new meadows and pastures are also discussed.

The care of permanent meadows and pastures, H. LANG (*Landw. Hefte*, 1913, No. 13, pp. 32).—This article discusses the artificial and natural methods of regulating the stand of grasses, combating pests, fertilization, irrigation, drainage, and the rejuvenating of permanent meadows and pastures.

The production of grass and hay, C. M. CONNER (*Philippine Agr. Rev. [English Ed.]*, 6 (1913), No. 2, pp. 81-85, pl. 1).—This paper gives descriptions of the production and uses of the native grasses, barit (*Leersia hexandra*), luyaluya (*Panicum repens*), and manimanian (*Alsicarpus*).

Propagating abacá (Manila hemp) from seed, M. M. SALEEBY (*Philippine Agr. Rev. [English Ed.]*, 6 (1913), No. 2, pp. 99-101).—Successful trials in propagating *Baguisanon lawaan* and the Pulajan and Tangongon varieties from seed are noted.

The renovation of the abacá (Manila hemp) industry, M. M. SALEEBY (*Philippine Agr. Rev. [English Ed.]*, 6 (1913), No. 4, pp. 167-182, pls. 5).—This article discusses suitable cultural methods, planting, renewal of old plantations, improvement of the quality of the fiber, and adjustment of relations between buyers and producers, with regard to Manila hemp in the Philippine Islands.

Experiments with alfalfa in 1910 at Turkestan Agricultural Experiment Station, P. SHREDER (*Turkest. Selsk. Khoz.*, 1911, No. 5; *abs. in Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.)*, 13 (1912), No. 3, pp. 444, 445).—In studying the influence of slope of the field on the yield of alfalfa it was found that results on a 4 to 5° slope were slightly better than on a 2 to 3° slope. Better yields were produced with barnyard manure than with superphosphate 4 years after application, and in comparing bone meal and ashes the latter was found to have made better yields on a 7-year-old field. In an experiment comparing superphosphate, Thomas slag, bone meal, and barnyard manure, superphosphate gave the best results the second year after application. It was found that alfalfa seed from England, France, Russia, and Germany produced better than native seed.

Barley, H. QUANTE (*Die Gerste. Berlin*, 1913, pp. 195, figs. 35).—This book treats of the morphological, anatomical, and chemical characteristics of barley, its history, development, botanical relations, and varieties; describes brewing valuations, according to the Vienna, Berlin, and Haase systems; and discusses methods of cultivation, harvest, storage, and artificial drying of the grain.

Svalöf golden barley, H. TEDIN (*Sveriges Utsädesför. Tidskr.*, 23 (1913), No. 1, pp. 27-50, pl. 1).—This article discusses the origin of this new variety of barley, the chief characteristics of which are its heavy yield of grain, resistance to smut (*Ustilago carbo*), and quick curing of the grain after harvest.

Cultural experiments at Stettin, K. STÖRMER (*Deut. Landw. Presse*, 40 (1913), Nos. 5, pp. 47, 48; 6, pp. 58, 59).—These articles report the results of

growing several varieties of barley on clay and sandy soils. The yields ranged from 811 to 2,150 lbs. of grain per morgen (1,285 to 3,410 lbs. per acre); 1,000 kernels weighed from 34.88 to 48.05 gm., and a hectoliter weighed from 63.9 to 69.65 kg.

New directions in the work of the selection of maize, I. ROSEN (*Khozâistvo*, 1912, No. 31, pp. 1013-1020; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 10, pp. 2156-2159).—This article discusses a system of producing and using the first hybrid generation to secure increased yields with maize, the objects of this system being to prevent self-fertilization and to keep the 2 parent strains pure. It is stated that the 2 strains may be kept pure by planting in alternate rows. The rows of 1 strain are topped the same year and from these the hybrid seed is obtained, while the plants of the other row supply the caryopses (for 2 years) required for the preservation and propagation of that strain; in the subsequent year the opposite plan is followed.

The following observations are noted: "The descendants of a self-fertilized plant are always less developed and productive than the descendants of plants naturally exposed in the fields to cross-fertilization; this is true both of superior individuals and individuals inferior in point of productivity to the average of the type to which they belong. The greatest diminution in the growth and yield in consequence of self-fertilization is found in the first generation, falling off gradually in the subsequent generations down to a constant value. The pure strains (or self-fertilized, coming from a single parent plant) are distinguished, among themselves, by transmissible morphological characters. The retrogression of the fluctuating characters is observed with greater frequency in proportion as we get farther away from the 'mean morphological type' characteristic of a 'pure strain.' The crossing between 'brothers' and 'sisters' (between male and female inflorescences, respectively, of 2 plants coming from a single parent plant and belonging to the same generation) presents no advantage over self-fertilization. Crossing between 2 self-fertilized strains of different types yields a progeny which is not inferior in force of growth and productivity to the plants never subjected to self-fertilization.

"In crossing 2 self-fertilized strains the results from the reciprocal crosses are identical. The seeds of F_1 obtained by crossing pure strains according to a determined scheme (combination) always exceed in yield the sowing material produced by irregular pollination in the fields, from which the 2 strains themselves were derived. The productivity and morphological characteristics of the hybrids of the first generation are therefore a function of that specified combination of pure strains, and are constantly repeated when the crossing is renewed. In the first generation of hybrids (F_1) the degree of variability of the individuals is not greater than that observed in the pure strains from which such generation sprang. In the second generation of hybrids (F_2) the degree of variability is higher than in F_1 . The productivity of F_2 is lower than that of F_1 ."

Variety tests of imported maize, A. H. ROSENFELD (*Rev. Indus. y Agr. Tucumán*, 3 (1912), No. 2, pp. 51-53).—Results are given of tests conducted with 16 varieties of maize. In general the yields were much better in 1912, ranging from 387 to 3,535 kg. than in 1911, when they ranged from 234 to 2,675 kg. of grain per hectare.

A new variety of maize, C. M. CONNER (*Philippine Agr. Rev. [English Ed.]*, 6 (1913), No. 2, p. 96).—This new variety is a cross between the Mexican June and a native white variety, and is named Moro. Preliminary tests have shown it to yield better than the small native varieties and to make good meal and

hominy. The ears average 19 cm. (7.4 in.) long and 5 cm. thick at the center and have 16 rows of grain.

Distance to plant maize, A. H. ROSENFELD (*Rev. Indus. y Agr. Tucumán*, 3 (1912), No. 6, pp. 231-235).—In this experiment plants spaced 125 cm. (about 49 in.) in rows 30 and 75 cm. apart gave better results than plants spaced 40, 75, or 100 cm. in rows spaced 30, 75, and 100 cm. apart. The check-row system, with hills of 3 or 4 plants about 1 meter apart, yielded about 30 per cent better than the row system.

Fertilizing maize (*Prog. Agr. y Pecuario*, 19 (1913), No. 818, pp. 258-260).—Results of the use of commercial fertilizers for corn in 3 different fields are given, in which increased yields were obtained at a profit by the use of the fertilizer.

The effect of water level on the yield of cotton (*Agr. Jour. Egypt*, 2 (1912), No. 1, pp. 37, 38, fig. 1).—The results of an experiment, in which the water level ranged from 0.8 to 2.2 meters (from 31 to 86 in.) below the ground surface, showed increased yields as the depth of water level increased.

A report on the production of new cottons, W. L. BALLS (*Agr. Jour. Egypt*, 2 (1912), No. 2, pp. 66-77, pls. 4).—This article gives the methods employed in crossing and the preventing of crossing, and discusses the time required for propagation, simple propagation of seed, a list of approximate constants, and possible rates of propagation. In some of the new cottons produced the mean maximum lint strength ranged from 27.7 to 33.5 mm.

Experiments in cotton cultivation at the experiment station of Karaiasi, Transcaucasia, V. DMITRIEVSKI (*Abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 11, pp. 2425, 2426).—This experiment was based upon the color of the cotton seeds, and as a rule the green seeds gave a more abundant and finer fiber than those of other colors. The results of planting seeds picked at different dates showed very little difference in yield or date of maturity, although the slight difference was in favor of the later picking.

Annual report of the government cotton station at Myombo (*Pflanzer*, 8 (1912), No. 6, pp. 323-334).—In a test of 6 varieties the yields of ginned cotton ranged from 52.6 to 213.2 kg. per hectare (46.8 to 189.7 lbs. per acre). Seed planted January 22 produced 196.4 kg.; that on February 3, 92.4 kg.; that on February 20, 34.8 kg.; and that on March 4, 10 kg. ginned cotton per hectare. When plants were thinned to 2 in a hill placed 100 by 80 cm. apart, the yields of ginned cotton were, on 2 plats, 129.2 and 138.4 kg. per hectare, respectively, and when thinned to only 1 plant per hill on 2 plats 53.5 and 42 kg. per hectare, respectively. Irrigation did not increase the yields.

Cowpeas, R. E. BLOUIN (*Rev. Indus. y Agr. Tucumán*, 3 (1913), No. 8, pp. 355-359).—Numerous varieties are described and methods of production, alone and in combination with maize and with cane, are discussed.

Don experiment field, I. KOLESNIKOV (*Abs. in Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.)*, 13 (1912), No. 3, pp. 448, 449).—The apparent increase in the yield of flaxseed for 9 years due to deeper plowing amounted to 14 per cent.

Fertilizers in the production of hemp, PALLADIUS (*Prog. Agr. y Pecuario*, 18 (1912), No. 770, pp. 261-264, figs. 4).—In these experiments it was found that the addition of potash to other fertilizers apparently increased the yield of fiber, in some cases more than 100 per cent. The yields ranged from 1,850 to 2,530 kg. per hectare (1,646 to 2,251 lbs. per acre).

Studies on hemp culture in Italy, W. F. BRUCK (*Tropenpflanzer*, 15 (1911), Nos. 3, pp. 129-141; 4, pp. 187-202; 5, pp. 244-264, figs. 6).—This article discusses the importance of the hemp industry in Italy, gives a brief historical review, including the development of hemp culture in different parts of the

country, and describes at greater length the Italian culture of the crop. The relation of hemp culture to farm management, farm labor, and export trade is also dwelt upon, and types of machines used in the different processes of preparing the fiber for market and for use are described.

New cover crop, F. G. SPRING (*Agr. Bul. Fed. Malay States*, 1 (1912), No. 1, pp. 13, 14).—This describes the horse gram (*Dolichos biflorus*), gives directions for its cultivation, and discusses its value as a cover crop for rubber plantations. Its chief value for this purpose lay in choking out weeds.

The Italian millet (*Setaria italica*) in Bengal, E. J. WOODHOUSE and A. C. GHOSH (*Dept. Agr. Bengal, Quart. Jour.*, 5 (1912), No. 4, pp. 180-186).—Detailed descriptions of several varieties of this millet are given, also the results of head selection during one season's work. It is noted that this crop seems well suited to Bengal conditions, producing yields when maize fails.

Philippine kapok: A promising new industry, M. M. SALEEBY (*Philippine Agr. Rev. [English Ed.]*, 5 (1912), No. 8, pp. 432-437).—This paper gives brief notes on the export trade of kapok in Java, the Philippines, and Dutch East India, and on the yield, value, and uses of the crop and its prospective cultivation in the Philippines.

Potato breeding, C. FRUWIRTH (*Deut. Landw. Presse*, 39 (1912), Nos. 47, pp. 551, 552; 48, pp. 565-567, figs. 4).—The author here relates his experience in hybridizing potatoes. Hand fertilization of the flowers proved unsuccessful. From a study of the plants produced from seed which was obtained from the balls produced by accidental crossing, or self-fertilization, it is noted that the offspring seldom, if ever, resembled the mother plant; that the long form was dominant over round; and that the red skin color of the tuber, the lilac color of the flower, and the yellow color of the tuber flesh were respectively dominant over white.

Notes on the propagation of Rhodes grass for hay, H. F. HUNGERFORD (*Philippine Agr. Rev. [English Ed.]*, 5 (1912), No. 8, pp. 438-443, fig. 1).—This paper suggests methods of propagation, irrigation, harvesting, and baling of Rhodes grass (*Chloris gayana*) for trial in the Philippines in the production of this grass for hay.

Selection of seed rice based on transparency, C. CREVOST (*Bul. Écon. Indochine, n. ser.*, 15 (1912), No. 96, pp. 388-392, figs. 2).—This article describes the method employed in seed selection of rice by passing before the rays of a lamp. Numerous varieties were thus selected and a maximum of 47 per cent, a minimum of 11.4 per cent, and an average of 22.3 per cent of inferior kernels were detected. Certain samples weighed 570 gm. per liter before selection and 620 gm. afterwards.

A description of the apparatus employed in this selection is given.

Data concerning varieties of rice, C. M. CONNER (*Philippine Agr. Rev. [English Ed.]*, 6 (1913), No. 2, pp. 86-92, figs. 4).—This paper records a continuation of work already mentioned (E. S. R., 28, p. 535), in which 279 varieties of white lowland rice grown in Indo-China were compared with a like number of lowland varieties grown in the Philippine Islands.

The greatest number of varieties matured within 6 months from sowing and the time to maturity had no relation to yield. It was found that the number of grains per head was in inverse ratio to the size of the grain, and that the size of the grain had little influence on yield. A distinguishing characteristic of the upland rice was that its average length and width of leaf was 41 and 20 per cent, respectively, greater than that of the lowland varieties.

Salt water rice, C. M. CONNER (*Philippine Agr. Rev. [English Ed.]*, 6 (1913), No. 2, p. 97).—Tests showed that a variety of rice found growing in sea water produced as well when irrigated with this water as it did with fresh water.

Samar (*Cyperus alopecuroides*) as a reclamation crop, J. D. SHEPHERD (*Agr. Jour. Egypt*, 2 (1912), No. 2, pp. 78-80, pl. 1).—A method of growing this crop (which is used to make mats, etc.) on land too wet for rice is described.

Magnesia fertilizer for sugar beets, F. STROHMER and O. FALLADA (*Österr. Ungar. Ztschr. Zuckerindus. u. Landw.*, 42 (1913), No. 2, pp. 221-231).—The results of fertilizing 3 plats with magnesium sulphate showed no variation in total yield, sugar content, or chlorophyll content of the beet leaves, over 3 untreated plats that could be attributed to the magnesium salt, which was applied at the rate of 150 kg. per hectare (133.5 lbs. per acre). A bibliography is appended.

Conditions of seed ball produced by stock beets of different sizes, T. REMY (*Zent. Ver. Rübenz. Indus. [Vienna]*, 51 (1913), No. 7, pp. 116, 117).—This article gives the results of experiments in producing seed from whole beets and divided beets (cuttings). It is noted that cuttings of from 100 to 150 gm. in weight, standing 70 by 80 cm. apart, produced as much seed as 10 times the same weight of whole beets standing 1 meter each way. The seeds from the cuttings seemed to have the same productive power as those from the whole beets.

The influence of light on sugar formation of beets, F. STROHMER (*Österr. Ungar. Ztschr. Zuckerindus. u. Landw.*, 42 (1913), No. 2, pp. 232-235; *Wchnschr. Zent. Ver. Rübenz. Indus. [Vienna]*, 51 (1913), No. 7, pp. 116, 117).—This article discusses further work (E. S. R., 28, p. 825) on the influence of light and shade on sugar-beet development in general, and gives results of the author's investigations. In these the percentage of sugar did not seem to change, but the total yield was considerably greater in direct sunlight than in shadow, ranging from 80.1 to 72.1 gm. per beet in the former and from 34.1 to 25.6 gm. in the latter case with 2 varieties.

Variety tests of sugar cane, A. H. ROSENFELD and J. A. HALL (*Rev. Indus. y Agr. Tucumán*, 3 (1913), No. 8, pp. 325-334).—This article gives the results of tests of over 70 varieties of cane in 1910-1912, in which the yields ranged from 88 to 6,774 kg. of sugar per hectare (78 to 6,029 lbs. per acre).

Tests in selection of sugar cane before planting, A. H. ROSENFELD (*Rev. Indus. y Agr. Tucumán*, 3 (1912), No. 1, pp. 1-5).—The methods of selection and cultivation are described. Germination in the field showed a ratio of the selected cane to the unselected of 153:44. The selected seed yielded 62,964 kg. of cane, which produced 3,425 kg. sugar per hectare, as compared with 51,216 kg. cane yielding 1,975 kg. of sugar per hectare. It is also noted that only about 37 per cent of the crop from the selected seed was injured by worms, as compared with 60 per cent of the unselected crop.

Sugar-cane experiments in Antigua and St. Kitts, 1910-11, H. A. TEMPANY (*Jour. Bd. Agr. Brit. Guiana*, 6 (1912), No. 2, pp. 58-60).—Results of variety and manurial tests are given. Nitrate of soda and sulphate of ammonia at the rate of 40 and 60 lbs. per acre in a single application apparently increased the yields, while phosphoric acid and potash gave no increase.

The crops on the experimental sugar-cane fields, 1911, J. B. HARRISON and F. B. STOCKDALE (*Jour. Bd. Agr. Brit. Guiana*, 5 (1912), No. 4, pp. 212-230).—In variety tests the yields ranged from 1.48 to 3.37 tons sugar per acre. In fertilizer tests better results followed the application of about 300 lbs. per acre of sulphate of ammonia than that of other fertilizers.

Experiments in the cultivation of sugar cane in 1912 and 1913, R. E. BLOUIN (*Rev. Indus. y Agr. Tucumán*, 3 (1913), No. 10-11, pp. 418-477).—This article gives notes and data on varieties tested, methods of cultivation, the use of fertilizer plus lime, selection, rotations, and distance in planting.

A new earth nut, O. W. BARRETT (*Philippine Agr. Rev. [English Ed.]*, 6 (1913), No. 2, pp. 104, 105).—It is noted that this new nut has been discovered in West Africa and is known as *Voandzeia poissoni*, or *Kerstingiella geocarpa*.

Xenia in wheat, L. BLARINGHEM (*Compt. Rend. Acad. Sci. [Paris]*, 156 (1913), No. 10, pp. 802-804, fig. 1).—The author describes a hybrid that he produced and which, it is claimed, showed the influence of the pollen in the size and shape of the caryopsis and in the morphological characters of the albumin. Tabulated measurements of kernels are given.

Notes on wheat, J. CASCÓN (*Bol. Agr. Téc. y Econ.*, 2 (1910), No. 22, pp. 373-382; 3 (1911), Nos. 25, pp. 86-91; 35, pp. 1041-1048; 4 (1912), No. 47, pp. 1035-1047, pls. 3).—These reports give the results of variety tests and other data on the measurements of wheat, barley, and oats grown in 1910-1912 in Spain. Improvements in yields and conditions in general are noted from year to year, especially with foreign introductions.

In 8 varieties of wheat grown in 1912 the average length of heads ranged from 9.4 to 16.3 cm. The weight of 10 heads ranged from 15.6 to 28.5 gm.; the average weight of individual heads from 1.56 to 2.85 gm.; the weight of grain from 10 heads of each variety, from 11.7 to 20.6 gm.; the number of kernels per head, from 29.5 to 49.4 gm., and the weight of 1,000 kernels, from 36.3 to 53.95 gm. The volume of 1,000 kernels ranged from 28.8 to 41.5 cc.; the volume of 1 liter, 525.4 to 681.7 cc.; the specific gravity from 1.25 to 1.62, and the number of kernels per liter from 16,137 to 22,746. The number of kernels per kilogram ranged from 18,533 to 27,548, and the weight of 1 liter of kernels from 824.6 to 880.2 gm. The yields of wheat per hectare ranged from 2,366 to 3,351 kg., and barley from 3,987 to 4,100 kg. Oats yielded 2,115 kg.

Results of fertilizer experiments with wheat, barley, and oats, and the analyses of wheat flours for 1912 are given in tabular form.

Observations on stooling in cereals at the Poltava Experiment Station, P. LESHCHENKO (*Khutorūnin*, 1911, No. 40; *abs. in Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.)*, 13 (1912), No. 3, pp. 478, 479).—Eight plants of winter wheat and 10 of spring wheat were selected and placed under observation, the time of appearance of the heads of each stem being noted in order to determine the relation to yield.

From the collected data it appears that the later the heads formed and developed the less was the yield. Determinations were made of the length and weight of each head and of the weight and number of kernels of each head. The author further observed that plants in cases of intense stooling lost enormous quantities of energy in producing barren stalks. None of the plants with an average of 20 stalks had more than 12 stalks which produced heads.

Determination of the germinative ability and germinative strength of seeds, W. OETKEN (*Deut. Landw. Presse*, 40 (1913), Nos. 24, pp. 287, 288; 25, p. 305; 27, pp. 329, 330; 28, p. 337, figs. 2).—The author first sets forth the difficulty of getting results with germination tests in the laboratory which correspond to field results with exactness, because of the "artificial" seed beds and other "artificial" conditions commonly used in the laboratory. It is noted that, to secure the desired results with seed germination, tests must be conducted with the 4 following points in view: To secure natural temperature conditions in order to promote rapid germination; to secure uniform resistance to vegetative energy; to cover a definite period of growth so as to determine the rate of development of the seedlings by weight of dry matter produced; and to determine the degree of health of the seedling as soon as it appears.

In a test with peas to determine the efficiency of sand and soil as germinating mediums, the percentage of germination in the sand ranged from 85 to 100 per cent, in the soil from 24 to 86 per cent, and in the field from 15 to 68 per cent. In testing the advisability of taking the weights of the seedlings at the end of a definite period, in order to determine the relative vegetative energy, it was found that samples of winter wheat showing 90, 71.25, 21, 36, 60, 48.25, and 46 per cent weighed, respectively, at the end of 10 days, 5.30, 3.79, 28, 1.65, 69, 2.27, and 57 gm. With spring wheat the variation between germinative ability and weight of seedling was even greater.

Report of the superintendent of the seed and weed branch, A. McKENNEY (*Ann. Rpt. Dept. Agr. Alberta, 1911, pp. 133-140*).—The methods described as being the most successful in the eradication of stinkweed are summer fallow and spring harrowing. For wild mustard, spraying with a 20 per cent solution of iron sulphate or a 2 per cent solution of copper sulphate is recommended, and for Canada thistle, continued cutting off at or below the surface of the ground.

Tabulated data of results of inspection of cars of seed supplied the farmers by the Dominion government are included.

Agrostemma githago and *Polygonum convolvulus*, N. SKALOSUBOW (*Trudy Būro Prikl. Bot. (Bul. Angew. Bot.), 4 (1911), No. 11, pp. 562-565*).—This article discusses the prevalence of these weeds in western Siberia and the value of the seeds and meal as feed for live stock.

HORTICULTURE.

The propagation and pruning of hardy trees, shrubs, miscellaneous plants, with chapters on manuring and planting, J. C. NEWSHAM (*London, 1913, pp. XIV+224, pls. 57*).—A practical treatise on plant propagation and pruning, in which consideration is given to fruit trees, ornamental deciduous trees and shrubs, and evergreen trees and shrubs, as well as to stove and greenhouse foliage and flowering trees and shrubs.

Practical tree repair, E. PEETS (*New York, 1913, pp. IV+265, pls. 16, figs. 62*).—A practical treatise on the physical repair of trees, such as bracing and the treatment of wounds and cavities. Chapters on boring insects and their control and rot fungi and their work are included.

The use of arsenicals for plant protection, with special reference to lead arsenate, L. FULMEK (*Arch. Chem. u. Mikros., 6 (1913), No. 6, pp. 347-408*).—A review of our knowledge relative to the use of arsenicals in various countries for the protection of plants. An extensive bibliography is appended.

The effect of bastard trenching on the soil and on plant growth, S. U. PICKERING and E. J. RUSSELL (*Jour. Agr. Sci. [England], 5 (1913), No. 4, pp. 483-496*).—The purpose of the experiments here reported was to determine the value of subsoiling without the addition of farmyard manure or other fertilizing material. The bulk of the experiments extended over the four seasons from March, 1909, to the end of 1912. Four distinct types of soil, including a light sand, two rather heavy loams, and a strong clay, were investigated. Trenching was effected by removing the first and second spades of soil. The third spade was broken up but not removed, and then the second and first spades were replaced in their natural order. Nothing was buried in the trench. Samples of soil were periodically taken for determinations of moisture and nitrates and observations were made on the growth of fruit trees on the plats.

Taking the evidence as a whole the effect of bastard trenching on the soil when unaccompanied by manuring is very small. Beyond a tendency to facilitate the drainage of water in the clays and the heavy loams and slightly to increase the nitrates no definite change seemed to be produced. As exemplified

by these experiments and by results obtained in some earlier experiments on the same plat of ground the effect on the growth of trees appears to depend largely on the character of the seasons following the trenching and planting. Generally speaking the author concludes that in the absence of a hardpan the main use of trenching seems to be that it affords an opportunity for adding manure or other fertilizer material to the soil.

An economic study of beans, E. M. LEDYARD (*Philippine Agr. and Forester*, 2 (1912), No. 4-6, pp. 66-85).—An economic and cultural test of a number of different species of beans is reported. The author concludes that on account of its wide adaptation as regards soil and its value as a garden and field bean, and also as a soil improver the cowpea is well adapted for general introduction into the Philippine Islands. The cowpea resembles the Philippine sitao which is a favorite bean for culinary use in the islands.

Supplementary studies on the differential mortality with respect to seed weight in the germination of garden beans, J. A. HARRIS (*Amer. Nat.*, 47 (1913), Nos. 563, pp. 683-700; 564, pp. 739-759, figs. 5).—In an earlier study of field cultures of *Phaseolus vulgaris* the author found that both large and small seed are less capable of developing into fertile plants than are those which do not deviate so widely either above or below the type (E. S. R., 28, p. 636). In order to substantiate these results greenhouse plantings in sand of some 46,000 individually weighed seeds, chiefly of the pedigrees employed in the field experiments, were made. The present paper discusses the results of this second study with special reference to the questions of the existence of a differential mortality and of its consequences in the population.

In general the results of the first study are fully confirmed. As a result of the more extended data secured from these greenhouse cultures, the author is led to conclude that there is strong evidence for varietal differences with respect to mortality. In some strains the heavier, in others the lighter, seeds seem less capable of development. From the data at hand no definite conclusion is drawn relative to the cause of this variation, but it is suggested that the reason for these differences may be sought in the inherent characters of the stocks used or the environment to which they have been subjected.

The author's studies are to be continued for the purpose of determining the causes of the observed differences in viability.

The pollination of fruit trees and its bearing on planting, C. H. HOOPER (*Gard. Chron.*, 3. ser., 54 (1913), Nos. 1406, pp. 393, 394; 1407, p. 420).—A review of recent European investigations on this subject, all of which tend to show that cross-pollination is the rule and that this is effected more by insects than by the wind. Honeybees and bumblebees are the best pollenizers. See also a previous note (E. S. R., 28, p. 237).

On the pruning and spacing of grapevines, J. L. VIDAL (*Rev. Vit.*, 39 (1913), Nos. 1013, pp. 689-693; 1014, pp. 713-720; 1015, pp. 752-756; 1017, pp. 814-819; *Bul. Agr. Algérie et Tunisie*, 19 (1913), Nos. 15, pp. 305-319; 16 pp. 321-331).—The author here reports a comparative test of various systems of pruning and spacing grapes as conducted with vines grafted to 24 different stocks. Information is also given relative to the value of these stocks for a limey soil.

On the behavior of various grape stocks on heavy calcareous soil, H. FAES (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 34 (1913), No. 50, pp. 743-746).—Summarized data are given showing the annual condition of Chasselas grapes grafted on various American and French-American grape stocks and set out on a heavy limey soil in 1909. Generally speaking the French-American stocks have been somewhat superior to the pure American stocks in their resistance to adverse soil conditions.

The hybrid direct bearers in the valley of the Rhone in 1912, A. DESMOLINS and V. VILLARD (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 34 (1913), No. 40, pp. 433-436).—In continuation of previous observations relative to hybrid direct bearing grapes (E. S. R., 27, p. 540) the results for the first season are given of observations which deal with the time at which the different varieties start growth in the spring. These observations are to be continued for a number of years.

Date growing in the Old World and the New, P. B. POPENOE (*Altadena, Cal.*, 1913, pp. XVIII+316, pls. 40).—In part 1 of this work the author gives a detailed account of commercial date growing in the Old World and in the United States, including methods of propagation, cultural operations, handling the crop, artificial ripening, diseases and pests, the classification of dates, profit of date growing, and uses of the date, with a chapter on its food value by C. L. Bennett. Part 2 contains a descriptive list of the important varieties which are now being grown in the United States.

Tea, EDITH A. BROWNE (*London*, 1912, pp. VIII+88, pls. 23).—A descriptive account of the tea industry in various countries.

Fertilizers and the freezing of nut trees (*Rev. Sci. [Paris]*, 51 (1913), II, No. 26, p. 813).—Brief reference is made to experiments in which the winter application of mineral fertilizers not only increased the vigor and yield of almond trees but apparently increased their resistance to cold to a marked extent.

Indoor gardening in room and greenhouse, H. H. THOMAS (*London, New York, Toronto, and Melbourne*, 1912, pp. 152, figs. 149).—A popular treatise on the culture of house and greenhouse ornamentals with a working calendar for the year. A chapter on the forcing of grapes is also included.

The hardy flower book, E. H. JENKINS, edited by F. W. HARVEY (*London and New York*, 1913, pp. XIV+143, pl. 1, figs. 50).—This work is offered as a complete guide to the methods of planting and cultivating hardy flowers. Part 1 deals with the principal uses of hardy flowers and discusses in detail some of the more important families as well as the proper grouping of plants for borders. Part 2 consists of an alphabetical list of all hardy herbaceous flowers considered worth growing, together with concise directions for their treatment. Part 3 consists of tabulated lists of hardy plants for all purposes.

The florist's bibliography: Supplement and index, C. H. PAYNE (*London*, 1912, pp. 79-100+VIII).—This publication, which supplements a handbook issued in 1908 (E. S. R., 21, p. 46) contains a list of recent references to books and treatises devoted primarily to florist's flowers and the flower garden.

FORESTRY.

Annual report on the progress, literature, and important happenings in the realms of forestry, hunting, and fishing for the year 1912, H. WEBER (*Allg. Forst u. Jagd Ztg.*, 1913, Sup., pp. VIII+199).—As in previous years (E. S. R., 27, p. 845), this supplement contains abstracts of the more important literature of the various phases of forestry, together with notes on the principal occurrences relating to forestry, hunting, and fishing during 1912. As in the last supplement, the international scope of the literature reviewed has been strengthened.

The present situation of forestry, H. S. GRAVES (*Proc. Nat. Conserv. Cong.*, 4 (1912), pp. 318-327).—An address on this subject delivered before the Fourth National Conservation Congress, Indianapolis, October, 1912, in which the author reviews the progress of federal and state forestry in the United States.

Forest map of Brazil, G. DE CAMPOS (*Relat. Min. Agr. Indus. e Com.*, Brazil, 1911, No. 3, pp. 1-98, pl. 1).—This comprises a map including descriptive text of the forest areas in Brazil, which has been prepared in connection with a proposed establishment of forest reserves in that country.

Reconnaissance in the Cotteswolds and the Forest of Dean, A. G. TANSLEY and R. S. ADAMSON (*Jour. Ecology*, 1 (1913), No. 2, pp. 81-89).—The results are given of a reconnaissance survey in the above-named forests with special reference to tree association and ground vegetation.

The forests and forestry of Germany, W. R. LAZENBY (*Pop. Sci. Mo.*, 83 (1913), No. 6, pp. 590-598, figs. 5).—A popular descriptive account.

Botanical and colonial economic studies of the bamboos, C. C. HOSSFUS (*Bot. Centbl., Beihefte*, 31 (1913), 2. Abt., No. 1, pp. 1-69, figs. 12).—This paper, which consists largely of a compilation of information relative to the economic uses of the bamboo, was prepared with special reference to the extension of bamboo culture in the German colonies.

The culture of *Manihot glaziovii* in East Africa, P. JANSSENS (*Bul. Agr. Congo Belge*, 4 (1913), No. 3, pp. 670-689, pl. 1, figs. 13).—A report on the development of the plantation rubber industry in East Africa with special reference to *Manihot* rubber. Information is given relative to general cultural practices, tapping operations, rubber coagulation, and preparation for market.

On the economic value of sal (*Shorea robusta*), R. S. PEARSON (*Indian Forest Mem., Econ. Ser.*, 2 (1913), No. 2, pp. VI+76, pls. 8).—This work deals with the economic uses of the sal tree. The subject matter is discussed under the following general headings: The physical and mechanical properties of sal timber; the durability of sal timber; uses of sal timber and minor products obtained from the tree; sal fuel; and outturn and prices of sal timber.

The wild plants of the South Kamerun forests used by the natives, J. MILDBRAED (*Notizbl. K. Bot. Gart. u. Mus. Berlin*, 1913, App. 27, pp. 43).—This comprises a descriptive account of a large number of plants which are utilized by the Bulus in South Kamerun for various purposes.

The present status of the forest seed origin question, A. ENGLER (*Naturw. Ztschr. Forst u. Landw.*, 11 (1913), Nos. 10, pp. 441-463; 11, pp. 481-491).—A popular review of the author's long-continued investigations, previously noted (*E. S. R.*, 29, p. 841).

Coast sand dunes, sand spits, and sand wastes, G. O. CASE (*Surveyor*, 44 (1913), Nos. 1129, pp. 352-358; 1130, pp. 388-393; 1131, pp. 424-427; 1132, pp. 460-463; 1133, pp. 496-499; 1134, pp. 536-538; 1135, pp. 576-580; 1136, pp. 616-620; 1137, pp. 660-662; 1138, pp. 696-699, figs. 43).—This comprises a résumé of the work accomplished and the methods employed in various countries in the fixation of sand dunes and the reclamation of sand wastes, including many references to the literature on the subject.

Forest fires in North Carolina during 1912 and national and association cooperative fire control, J. S. HOLMES (*N. C. Geol. and Econ. Survey, Econ. Paper* 33, 1913, pp. 58, fig. 1).—In this paper the author gives a record of forest fires in North Carolina during 1912 with comparative data for previous years, together with a general account of the progress made in the control of forest fires by the federal and state agencies and by private associations.

In North Carolina the State has no organized fire protective system. The total loss from forest fires during the past 4 years is estimated at over \$2,500,000.

Practical experiences in the use of fluorids for wood preservation, R. NOWOTNY (*Ztschr. Angew. Chem.*, 26 (1913), No. 93, Aufsatzteil, pp. 694-700).—The author here presents data showing the results secured in different parts of Austria in the use of various fluorid compounds for preserving telegraph poles, etc. Summarizing the results as a whole the zinc fluorid and sodium fluorid compounds have proved to be strongly antiseptic against wood-destroying fungi and much superior to copper sulphate and zinc chlorid.

A number of references to the literature on the use of fluorid for preservative purposes are cited.

DISEASES OF PLANTS.

The fungus diseases of agricultural plants, J. ERIKSSON, trans. by A. Y. GREVILLIUS (*Die Pilzkrankheiten der landwirtschaftlichen Kulturpflanzen. Leipsic, 1913, pp. XVI+246, pls. 3, figs. 130*).—This is a German edition of a book previously noted (E. S. R., 28, p. 345).

Annual report on plant diseases, 1911, M. HOLLRUNG (*Jahresber. Pflanzenkrank., 14 (1911), pp. VIII+410*).—This report, published in 1913, continues the general plan of its predecessors (E. S. R., 28, p. 345), the literature cited for 1911 including 2,360 titles.

A preliminary host index of the fungi of Michigan, exclusive of the Basidiomycetes, and of the plant diseases of bacterial and physiological origin, G. H. COONS (*Rpt. Mich. Acad. Sci., 14 (1912), pp. 232-276*).—Lists are given of parasitic fungi observed as occurring on various host plants in Michigan.

Report on the work of the phytopathologist at Wageningen for 1911, J. RITZEMA BOS (*Meded. Rijks Hoogere Land, Tuin en Boschbouwsch. [Wageningen], 6 (1913), No. 3, pp. 105-163*).—This is an account of observations and experiments reported in relation to plant disorders due to inorganic agencies, attacks by plant or animal enemies, or undetermined causes.

Report of the botanical laboratory and laboratory for plant diseases, L. LINSBAUER, F. ZWEIFELT, and H. ZUDERELL (*Programm u. Jahresber. K. K. Höh. Lehranst. Wein u. Obstbau Klosterneuburg, 1912-13, pp. 159-178, figs. 3*).—A report is given on various investigations on plant diseases and insect pests, together with means adopted for their control. The principal investigations were carried on with those pests attacking orchard fruits, grapes, berries, potatoes, vegetables, and ornamentals.

Plant diseases observed in 1912 at the agricultural academy at Kolozsvár, B. GROF (*Kísérlet. Közlem., 16 (1913), No. 2, pp. 271-277, pl. 1*).—*Phoma fœniculina* is reported from the same locality as in the previous year. *Puccinia malvacearum* is said to infest not only *Althæa rosea nigra*, but also seriously *A. officinalis* in the neighborhood and sporadically *Malva sylvestris* and *M. vulgaris rotundifolia*, which are suspected to constitute a medium for the probable adaptation of this fungus for living on *A. officinalis*. *Plasmopara nivea* was noted on leaves of *Conium maculatum* living through the winter, appearing about May 15 and showing oospores about August 15. *Puccinia bullata* appeared about the same time on leaves, petioles, and twigs of the same host, showing its fruiting bodies about the same time and evidently inflicting considerable injury.

Agricultural botanical notes from the experimental plats at Ultuna, 1912, E. HENNING (*Sveriges Utsädesför. Tidskr., 23 (1913), No. 2, pp. 129-141, fig. 1*).—Discussions are given of the development of the winter wheat plants in the late fall of 1911, the size of leaves of the wheat varieties at time of blooming, mealy and glassy winter wheat kernels, the appearance of yellow and black rust (*Puccinia glumarum* and *P. graminis*) on small grains, and infection experiments with loose smut of barley (*Ustilago nuda*).

A contribution to the mycological flora of Russia, N. NAOUMOFF (*Bul. Trimest. Soc. Mycol. France, 29 (1913), No. 2, pp. 273-278, pl. 1; abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 4 (1913), No. 7, p. 1115*).—Preliminary to publication of a fuller list of collections in Russia, the author notes three species of fungi obtained in the summer of 1912, which are described under the respective names of *Bremia graminicola* n. sp. (on leaves of *Arthraxonis ciliaris*), *Cicinnobolus bremiphagus* n. sp. (pycnidia of which were attached to fruiting organs of *B. graminicola*), and *Rhodoseptoria ussuriensis* n. g. and sp., destroying leaves and fruit of the Manchurian plum.

Amygdalase and amygdalinase in *Aspergillus niger* and related Hyphomycetes, M. JAVILLIER and MME. H. TCHERNOROUTZKY (*Ann. Inst. Pasteur*, 27 (1913), No. 6, pp. 440-449).—The authors state, as the result of a study of *A. (Sterigmatocystis) niger* and some related fungi, that most of these are unequally rich in the two diastases, amygdalase and amygdalinase, a low percentage of zinc in the culture medium corresponding to a deficiency of both; also that in most of the fungi studied, the first named enzym predominates, the proportions varying somewhat with the age of a given culture.

Morphological alterations in *Aspergillus niger* grown in various acids and acid salts, A. KIESEL (*Ann. Inst. Pasteur*, 27 (1913), No. 6, pp. 481-488, pls. 2).—Pursuant to previous reports (E. S. R., 29, p. 734), the author figures and describes numerous alterations in mycelial growth and in cellular size, form, vacuolation, granulation, etc., noted in case of *A. niger*, grown in various media.

Some factors which influence the development of *Penicillium glaucum*, H. I. WATERMAN (*Over eenige factoren, die de ontwikkeling van *Penicillium glaucum* beïnvloeden. Proefschr. Tech. Hoogeschool Delft, 1913, pp. 157*).—Summarizing the results of an extended study of factors affecting the development of *P. glaucum*, the author states that the number and variety of organic compounds which in suitable concentration may serve as the carbon source in the development of *P. glaucum* is very large, but that highly oxidized compounds take no part in its development. The compounds which are harmless in moderate concentration are not all assimilable. A few aromatic compounds may serve as exclusive sources of organic nutriment for this fungus.

The occurrence of smut on the seed of some grasses, H. M. QUANJER (*Tijdschr. Plantenziekten*, 19 (1913), No. 5, pp. 137-152, pls. 2).—The author describes the occurrence of *Ustilago bromivora* on species of brome grass, particularly *Bromus unioloides*. It has been claimed that the beetle *Phalacrus curruscus*, through eating the spores of this smut, aids materially in keeping the disease under control, but the author believes that it is not so efficient as has been reported. For the control of the disease he recommends soaking the seed in a solution of copper sulphate or treating with hot water. Both of these methods have reduced the amount of smut, but the best results were obtained with the hot water treatment. Formaldehyde has also been recommended and has been used with some success.

The occurrence of rust spores in the interior of seeds of grasses, J. BEAUVERIE (*Compt. Rend. Acad. Sci. [Paris]*, 157 (1913), No. 18, pp. 787-790).—The author reports having observed pustules containing spores of rust in wheat, barley, *Bromus mollis*, and *Agropyron* spp. The presence of the rust in these seeds is believed by him to be of great importance when considered from the standpoint of the propagation of rusts.

Injury from rust fungi, D. HEGYI (*Kísérlet. Közlem.*, 16 (1913), No. 4, pp. 544-553).—Experiments are said to show that several common treatments for smut fungi are ineffective, but that treating the seed with either 1 per cent copper sulphate or 0.13 per cent formalin is safely protective. It is also stated that injury due to stinking smut is probably much greater than has hitherto been thought, requiring a more thorough study of this fungus.

Longevity of loose smut of barley in case of infected seed, H. ZIMMERMANN (*Ztschr. Pflanzenkrankh.*, 23 (1913), No. 5, pp. 257-260).—Reporting on a continuation of work previously noted (E. S. R., 25, p. 244), the author gives tabular results of experimentation with 18 varieties of barley during 1908 to 1912. He concludes that the ability of *Ustilago hordei* to develop loose smut in barley appears to depend largely upon the stage of development of the variety in question, the time as well as the violence of attack varying in dif-

ferent seasons; also that the smut may remain capable of development for about five years.

Effects on winter rye and wheat of treatment with corrosive sublimate, L. HILTNER (*Prakt. Bl. Pflanzenbau u. Schutz, n. ser.*, 11 (1913), No. 8, pp. 101-104).—Continuing previous reports (E. S. R., 28, p. 846), the author gives the results of numerous practical experiments reported by farmers with the corrosive sublimate treatment. This is said to have been beneficial to both wheat and rye against *Fusarium*, but not against loose smut of wheat.

Corrosive sublimate as treatment for rye, K. GRÄF (*Prakt. Bl. Pflanzenbau u. Schutz, n. ser.*, 11 (1913), No. 8, pp. 97-101, figs. 4).—Very favorable results are reported as following the use of corrosive sublimate against *Fusarium* on seed grains of winter rye in 1912 as recommended by Hiltner. The effects of Sublimiform on the spring planting were not very decided, possibly on account of weather unfavorable to the development of the fungus.

The effect of formalin and copper sulphate solution on the germination of wheat, C. C. BRITTELBANK (*Jour. Dept. Agr. Victoria*, 11 (1913), No. 8, pp. 473-476, figs. 2).—The results are given of an experiment undertaken to ascertain the effect of time on the germination of wheat after treatment with formalin and copper sulphate solutions. Equal quantities of seed were soaked for 5 minutes in a solution of formalin, 1:300, and for 1 minute in a 2 per cent solution of copper sulphate. The seed was then removed from the solutions, dried, placed in clean bags, and tested at weekly intervals for 54 weeks.

Marked differences in vigor and growth of the plants were noted from the first. The control lot was the quickest to germinate, and gave an average of 95 per cent germination for the entire period. Next in germination and vigor was the seed treated with formalin solution, for which an average germination of 91 per cent was found. The highest percentage of germination for copper sulphate was 95 per cent at the end of the first week. Following this there was a gradual reduction in viability until at the end of the period only 32 per cent germinated.

This experiment indicates that seed should be sown as quickly as possible after treatment.

Connection between the acidity of the cell sap and rust resistance in wheat, O. COMES (*Atti R. Ist. Incoragg. Napoli*, 6. ser., 64 (1912), pp. 418-441; *abs. in Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 7, pp. 1117-1119).—This work, dealing with results obtained previously by the author and others, is believed to justify the general conclusion that the biochemical factor which constitutes the means of resistance of an organ to disease may be estimated from the acidity of the cell sap; that this acidity, rather than density and compactness of tissues, enables plants to resist parasitic fungi; and that the normal production of sap more or less rich in sugars or in acid is hereditary, but capable of modification by cultivation, manuring, and elevation. It is claimed that the farmer should give attention to biological means, such as hybridization and selection, in order to increase the resistance of improved plants, in this way seeking to discover the varieties resistant for a given district. In order to preserve the highest degree of acidity in the cell sap and at the same time maintain fertility of soil the phosphatic fertilizers, especially superphosphates, should be used instead of nitrogenous manures.

Foot disease of wheat, REUTHER (*Deut. Landw. Presse*, 40 (1913), No. 65, p. 780).—This brief discussion of the appearance, predisposing conditions, and probable causes of foot or stalk disease of wheat, concludes with recommendations looking to protection therefrom, the principal of which are included in

careful selection and preventive treatment of seeds, sparing use of nitrogenous manures, suppression of weeds, rotation, and proper drainage.

Observations on foot disease of wheat, REUTHER (*Illus. Landw. Ztg.*, 33 (1913), No. 65, pp. 589-591).—The main substance of this report is contained in the article noted above.

Nematode disease of wheat, J. APPL (*Wiener Landw. Ztg.*, 63 (1913), No. 69, p. 787, figs. 3).—The author reports briefly on infection and other studies carried out on wheat in relation to *Tylenchus tritici* in Austria.

The nematodes are said to invade the seedling from the soil when very young and to be carried upward with its growth, breeding in immense numbers in the galls found in the heads. It is supposed, however, that they can infect young plants only at short distances (probably not over 10 cm.) from the original host plants. The galls, however, which are said to be almost the sole means of spreading the infection, are distributed and sown with the seed wheat, but it is suggested that by winnowing and other means they may be largely removed, lessening greatly the danger from nematodes.

A disease of peanuts, A. A. L. RUTGERS (*Dept. Landb., Nijv. an Handel [Dutch East Indies], Meded. Afdeel Plantenziekten*, 1913, No. 6, pp. 5, pls. 2).—A description is given of a disease of peanuts in Java that is believed to be identical with that described by Zimmerman from German East Africa (E. S. R., 19, p. 448). No organism has been definitely determined as causing the disease, and experiments on its transmission and control have given negative results.

In addition to the peanut, the mungo bean (*Phaseolus mungo*), *Dolichos biflorus*, *Crotalaria verrucosa*, and probably *Triumfetta rhomboidea* are believed to be subject to this disease.

A contribution on changes in fleshy organs of plants due to micro-organisms, L. HAUMAN-MERCK (*Ann. Inst. Pasteur*, 27 (1913), No. 7, pp. 501-522).—As the result of a study of the relations between several fleshy plants and the organisms attacking them, the author states that in Argentina, as in North America, winter potato rot is caused by *Mucor stolonifer*; that infection, though ordinarily easy and quick in case of contused wounds, is unlikely in case of cut though unbruised tissues exposed to air, on account of rapid cicatrization in such cases; that whatever prevents or hinders such cicatrization in roots, tubers, leaves, etc., favors their immediate infection and possibly the development also of substances unfavorable to suberization; that, therefore, attack of an organ through a wound or bruise seems to depend upon the relative rate of development of the saprophyte in the superficial layers of contused cells and of suberin in the layers immediately beneath.

Leaf roll of potatoes, VI, G. KÖCK, K. KORNAUTH, and O. BROŽ (*Ztschr. Landw. Versuchsw. Österr.*, 16 (1913), No. 3, pp. 89-140, pl. 1, fig. 1; *abs. in Bot. Centbl.*, 123 (1913), No. 8, p. 200).—The authors give results of their 1912 studies on potato leaf roll, which are said to confirm those previously given (E. S. R., 27, p. 447). The trouble is claimed to be due to a parasitic *Fusarium*, which may invade the plant directly from the soil (primary infection), spreading in the vascular bundles to or throughout the tubers and developing in varying degree in the plants produced therefrom (secondary infection); or, not reaching the tubers but interfering with their nutrition, may simply dwarf these and successive crops therefrom. This trouble is claimed to be distinct from some others which wither or crinkle the leaves. It appears either early or late in the growing period. Numerous infection studies succeeded in reproducing the disease. No close relation to weather has been determined.

A list of the 1912 literature on this subject is appended.

Disorders and parasites of rice, L. GRANATO (*Bol. Agr. [Sao Paulo]*, 14. ser., 1913, No. 1, pp. 1-17).—This is a somewhat systematic general account of rice disorders as observed in Sao Paulo in recent years, including some observations on animal and cryptogamic parasites.

A sclerotial disease of rice, F. J. F. SHAW (*Mem. Dept. Agr. India, Bot. Ser.*, 6 (1913), No. 2, pp. 11-23, pls. 3).—The author states that *Sclerotium oryzae* has recently been demonstrated on rice in India, the attack manifesting itself through extensive tillering from the base of the infected culm. Inoculated laboratory plants died, while infected field plants were only weakened, failing to produce good seed. The fungus is said to show, according to the various substrata used, decided differences, these being most marked in the color and form of the hyphae. No trace of a perfect stage was observed. The sclerotia are thought to winter in the soil and to be practically beyond the reach of ordinary remedies. The breeding of resistant varieties of rice is suggested.

A bibliography is appended.

A disease of rice (*Agr. News [Barbados]*, 12 (1913), No. 298, p. 318).—This is a summary of the article above noted.

History of root rot or red rot of beets, A. STIFT (*Bl. Zuckerrübenbau*, 20 (1913), No. 15, pp. 225-230).—The author gives a condensed account of efforts to check this disease and of related writings during the last 60 years, closing with a reference to the means recommended by Eriksson (*E. S. R.*, 29, p. 50) for its control.

Recent studies with fertilizers as protective to beets against dry rot, heart rot, and nematodes, R. SCHANDER (*Bl. Zuckerrübenbau*, 20 (1913), No. 11, pp. 169-173; *Deut. Zuckerindus.*, 38 (1913), No. 7, pp. 154, 155; *abs. in Centbl. Bakt. [etc.]*, 2. Abt., 38 (1913), No. 7-12, pp. 246, 247).—The author states that calcium sulphate was ineffective as used against heart rot and dry rot of beets; that the free use of potassium, nitrogen, and phosphorus fertilizers increased considerably the yield of the beet crop on ground infested with nematodes; that shallow plowing as protection against nematodes was ineffective, proving also injurious to the beet crop where the above-named rots prevailed, and that the Kühn method of trap plants seems to be of limited adaptability for this purpose.

Protection against nematode injury, W. KRÜGER (*Centbl. Zuckerindus.*, 21 (1913), No. 15, p. 515; *abs. in Centbl. Bakt. [etc.]*, 2. Abt., 38 (1913), No. 7-12, pp. 167, 168).—In continuation of previous notes (*E. S. R.*, 27, p. 152) the author, discussing nematode injury to the beet crop and some difficulties of protection therefrom, states that field experiments have been continued at the experiment station at Bernburg to test the effects, as regards protection, of variations in soil absorptivity, in case particularly of phosphorus and potassium and in general of the more available compounds. It is held that loss as regards quantity and quality of the product is less when the supply of available nutriment is more plentiful.

Tomato diseases, T. C. WEBB (*Jour. Agr. [New Zeal.]*, 7 (1913), No. 1, pp. 46-52, figs. 2).—The results of experiments for the control of tomato diseases on plants grown under glass are given.

The tomatoes were sprayed with different fungicides, and from January until April were kept free from disease by the use of either Bordeaux mixture or Burgundy mixture. After April 5, owing to other work, a period of 3 weeks elapsed without spraying, when the tomato spot (*Cladosporium fulvum*) appeared on all the plants. Spraying with Bordeaux mixture at 10-day intervals held the disease in check, but the use of Burgundy mixture after April 5 was without any advantage.

The relation of fertilizers, temperature, and humidity to the disease are discussed and descriptions are given of nematode attacks, tomato spot, a disease called black stripe, and white fly injury.

Regarding the relation of fungus attack upon the foliage of trees to disturbances in roots and lower trunk, R. FARNETI (*Riv. Patol. Veg.*, 6 (1913), No. 4-5, pp. 97-107).—Discussing numerous examples cited, the author claims that functional disturbances, debility, and bad constitutional conditions generally do not necessarily predispose trees to fungus attack.

Diseases of the orchard, L. CAESAR (*Ann. Rpt. Fruit Growers' Assoc. Ontario*, 44 (1912), pp. 22-25, figs. 4).—Notes are given on black rot canker, apple scab, and pear blight, with suggestions for their control.

The transpiration of apple leaves infected with *Gymnosporangium*, H. S. REED and J. S. COOLEY (*Bot. Gaz.*, 55 (1913), No. 6, pp. 421-430, fig. 1).—Substantially noted from another source (*E. S. R.*, 29, p. 647).

The apple rust (*Rpt. W. Va. Dept. Agr.*, 1913, No. 29, pp. 20-24, fig. 1).—In a paper presented before the twentieth annual meeting of the State Horticultural Society attention is called to the rust of apples and its related form on cedars, with the object of reducing the occurrence of the disease as much as possible by the removal of cedar trees in the vicinity of orchards. It is stated that the disease can be controlled by proper spraying, but as the period when the application of the fungicide should be made is quite limited a more practical method of control is believed to be the elimination of the cedar trees.

The collar blight of apple trees, N. J. GIDDINGS (*Rpt. W. Va. Dept. Agr.*, 1913, No. 29, pp. 15-19, fig. 1).—In a paper presented before the twentieth annual meeting of the State Horticultural Society, the author states that three troubles of apple trees, collar blight, winter injury, and root rot, are frequently met with and often confused.

The collar blight disease, it is said, may be detected in its early stages by a close inspection of each individual tree. The affected trees usually show a discolored area of bark just above the ground, and the bark is frequently sunken. By cutting into the bark it is found to be dead and black, and a reddish discoloration is observed where the wood and bark come together. At later stages in the progress of the disease the dead bark often becomes broken up and rot fungi easily gain access. An examination was made of a number of orchards, and a considerable proportion of trees of bearing age was found affected.

The only remedy at present known is that of cutting out and treating the diseased areas. Differences are noted in the susceptibility of varieties of this trouble, and it has been suggested that double working nursery stock has given relief.

A bacterial canker of plum twigs, I. M. LEWIS (*Trans. Amer. Micros. Soc.*, 31 (1912), No. 3, pp. 145-149, pl. 1).—The author states that a disease of plum trees, popularly known as canker, is quite prevalent in portions of Texas and is apparently identical with that which has been reported from Nebraska and Delaware (*E. S. R.*, 18, p. 244; 19, p. 445). Small cankers are observed on the wood of the first season's growth, and these enlarge until finally the twigs may become completely girdled.

A bacterium (*Pseudomonas pruni*) has been isolated and cultivated, and inoculation shows that it is responsible for the trouble. In addition it was found possible to produce typical cankers on young peach trees with the organism taken from the plum.

Physiopathological observations on the stigma of the olive flower, L. PETRI (*Mem. R. Staz. Patol. Veg. Roma*, 4 (1913), pp. 139-160, figs. 7; abs. in

Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 4 (1913), No. 7, pp. 1113, 1114).—It is stated that among the external causes which may provoke alteration in the stigmatic papillæ and bring about their death are rain and mist, which act by wetting the stigma and causing arrest or excessive reduction of the activity of respiration, transpiration, and assimilation, by bringing about a toxic accumulation of oxalic acid.

The biology of *Cycloconium oleaginum*, L. PETRI (*Mem. R. Staz. Patol. Veg. Roma*, 1913, pp. 136, figs. 37; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 7, pp. 1116, 1117).—The author gives results of studies carried on since 1905 with cultures of *C. oleaginum*, and discusses artificial nutritive media, germinating conditions of the conidia, enzym action of the fungus upon the cuticle of the olive leaves, and localization and development of the disease as related to conditions of receptivity in the leaves.

It is stated that *Cycloconium* can grow saprophytically, forming in cultures its chlamydospores and microsclerotia, the conidia forming only in case of an acid substratum. Conidia are said to germinate at temperatures between 2 and 32° C., but cultures may live at -15°.

Two enzymes, pectin and lipase, were isolated from the cultures, but no toxic substances were shown to be elaborated by the mycelium. This fungus does not develop on leaves which are about to fall. Its germination at low temperatures and the physiological conditions of the leaves in winter render infection at that season possible, especially in southern and littoral districts.

Diseases and enemies of cacao, L. BEILLE (*Jour. Agr. Trop.*, 13 (1913), Nos. 144, pp. 167-172; 145, pp. 193-197; 146, pp. 236-238).—Besides a brief notice of general disorders which may be more or less common to roots, stems, branches, leaves, and fruit of cacao trees, a discussion is given of certain diseases peculiar to each part, including more or less of the history, cause, symptoms, remedies, etc. A section is devoted to animal pests of the cacao tree.

Premature leaf fall of currant bushes, E. NOFFRAY (*Jour. Agr. Prat.*, n. ser., 26 (1913), No. 35, pp. 272, 273; *Rev. Hort. [Paris]*, 85 (1913), No. 18, pp. 426, 427).—The author discusses briefly an attack of *Glæosporium ribis* on leaves of currant bushes, causing their early fall, followed by the development on the fallen leaves of *Pseudopeziza ribis*, said to be the perfect form of *G. ribis*.

Raspberry yellows and cane blight, J. E. HOWITT (*Canad. Hort.*, 36 (1913), No. 10, pp. 237, 238).—Descriptions are given of two serious diseases of raspberries that are said to be prevalent in Ontario.

The first, the cause of which is not determined, is called raspberry yellows from the general appearance of the affected plants. The first indication of the presence of this disease is said to be the curling downward of the margin of the upper leaves which later become mottled with yellow. As the disease progresses the plants become stunted and yellow and the berries dry up without ripening. This disease spreads rapidly through a plantation, and as yet no definite remedy is known.

The cane blight is due to a fungus, but it is not so widespread nor so serious as the yellows.

For both diseases the planting of healthy plants and the removal and burning of diseased specimens are about the only methods of control that are promising. The use of Bordeaux mixture or other sprays having failed to hold the diseases in check.

Treatment of court-noué with coal tar, LAMOUROUX (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 34 (1913), No. 40, pp. 417-421, figs. 2).—A brief account is given with illustrations of the method and results of applying coal tar to grapevines

dwarfed by court-noué. The vines showed improvement the first year, and more decidedly the second year. After the third year's treatment the recovery is considered to be complete, the new growths being apparently normal as to development and product.

Development of downy mildew as related to conditions of the medium, O. MENDEL (*Compt. Rend. Acad. Sci. [Paris]*, 157 (1913), No. 4, pp. 292-294).—Observations made at the station for agricultural meteorology at Perpignan are said to show that in this region, where the winds predominant in periods of mildew outbreak are from the sea, the localities of greatest infection are the elevations most exposed to sea winds presumably bearing comparatively few spores; this is apparently because of the greater humidity and warmth, favoring germination. In the observation period in question it is held that the two days of northwest showers conferred receptivity upon the grape stocks and that three days of warm moist winds from the northeast and southeast developed the infection.

Summarizing the conclusions arrived at from recent studies, the author concludes that the presence of mildew and degree of its attack depend upon general causes, such as variations of atmospheric conditions, which may be widespread; upon secondary causes, including such factors as the nature and vitality of the stock, the composition of the soil, and exposure of the situation; and upon accidental causes, such as fertilizers, dressings, and the presence of overflow water.

The white rot of grapes and its treatment, L. DEGRULLY (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 34 (1913), No. 36, pp. 289-291, pl. 1).—According to the author, the white rot due to *Coniothyrium diplodiella* is particularly destructive to the fruit of certain varieties of grapes. The fungus is considered to be semiparasitic, usually attacking the fruit and vine through wounds.

Spraying for black rot or mildew will at the same time protect against the occurrence of the white rot. The fungicides for this purpose should contain a large amount of copper.

This fungus, unlike the *Botrytis* which causes the gray rot, is said not to produce any oxidizing enzymes, and as a result does not affect wine.

Diseases of *Azalea indica*, H. BEHNSEN (*Gartenwelt*, 17 (1913), No. 36, pp. 499, 500).—A brief discussion is given of the injury to *A. indica* by *Fuligo septica*, requiring the removal of the slime mass and application of potassium nitrate; by *Septoria azaleæ*, Bordeaux mixture of 1 per cent strength being recommended as a preventive measure; by an *Exobasidium* of undetermined species, no remedy being prescribed; and by leaf fall ascribed to means used for securing rapid growth. Several injurious animals are briefly discussed.

Carnation stem rot, H. W. ANDERSON (In *Floriculture Research at the Experiment Station. Urbana: Univ. Ill.*, 1912, pp. 15-22).—This is a paper presented before the annual meeting of the Illinois State Florists' Association and consists of an account of observations and experiments on the carnation stem rot due to *Rhizoctonia*. An outline is given of experiments in progress relating to this disease, and a number of other fungus troubles are briefly mentioned.

Infection experiments with *Phoradendron villosum*, K. VON TUBEUF (*Naturw. Ztschr. Forst u. Landw.*, 11 (1913), No. 3, pp. 171, 172; *abs. in Bot. Centbl.*, 123 (1913), No. 12, p. 294).—Attempts to grow *P. villosum* on several European trees named gave no further results in any case than germination of the mistletoe seed. See also a previous note (E. S. R., 29, p. 243).

Notes on black canker of chestnut, E. BARSALI (*Riv. Patol. Veg.*, 6 (1913), No. 4-5, pp. 107-110).—Referring to recent reports by Petri (E. S. R., 29, p. 156) and others on black canker of chestnut, the author contributes some observations

regarding the presence and effects of *Coryneum* and other fungi on chestnut trees, stating no absolute conclusion at this time, but insisting on early attention being given to the root system in this connection.

Cryptogamic leaf diseases of Hevea in America, V. CAYLA (*Jour. Agr. Trop.*, 13 (1913), No. 144, pp. 186-188).—The author, noting briefly several studies made on the parasitism of *H. brasiliensis*, states that *Dothidella ulei* appears to attack most readily and severely plants reduced in vitality by unfavorable conditions. The disease is reported from the upper Amazon, but not in very severe form.

A blight of the mesquite, F. D. HEALD and I. M. LEWIS (*Trans. Amer. Micros. Soc.*, 31 (1912), No. 1, pp. 5-10, pl. 1).—A disease of mesquite (*Prosopis glandulosa*) has been under the authors' observation for several years. It is said to be quite abundant in the vicinity of Austin, Tex., and thought probably to occur throughout the range of this species.

The leaves are affected soon after the leaflets attain mature size, and in the early stages the leaflets show a form of chlorosis which begins at the margin and tip and advances until the midrib is reached. The general condition is such as is popularly designated as rust.

The fungus could not be referred to any known genus, and the authors have proposed for it the name *Scleropycnium aureum* n. g. and sp., a technical description of which is given.

The occurrence of the larch canker on Corsican pine, A. D. HOPKINSON (*Quart. Jour. Forestry*, 7 (1913), No. 4, pp. 287-290, pls. 2).—The author reports on the prevalence of the larch canker (*Dasyscypha willkommii*) on the Corsican pine. Of 100 trees examined, 90 showed signs of having been attacked by the fungus, but a few of the larger specimens that had been infected had overcome the disease and the wounds had begun to heal. In addition to the Corsican pine (*Pinus laricio*), this fungus is said to attack also the Scotch pine (*P. sylvestris*) and the Austrian pine (*P. austriaca*) in the same neighborhood.

An adherent spraying liquid, A. LECOMTE (*Rev. Vit.*, 40 (1913), No. 1027, pp. 225-228).—Noting the contributions of Vermorel and Dantony (*E. S. R.*, 29, p. 850) in regard to employment of casein to promote adherence in fungicidal sprays, the author reports the successful use for this purpose of this substance in its natural solution, milk. The mixture, it is claimed, was found to be entirely homogeneous when made with the percentage of copper usual in such sprays. A mixture of 2 per cent copper sulphate, 1 per cent lime, and 2 per cent milk in the aqueous solution is said to be satisfactorily adherent and not prohibitively expensive under favorable circumstances.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

A text-book of agricultural zoology, F. V. THEOBALD (*Edinburgh and London*, 1913, 2. ed., rev., pp. XX+536, figs. 257).—A revised edition of this work (*E. S. R.*, 11, p. 427).

The present status of the heath hen, G. W. FIELD (*Bird Lore*, 15 (1913), No. 6, pp. 352-358, figs. 9).—This paper relates to the occurrence of the heath hen, which has been exterminated except upon Marthas Vineyard. It is stated that 6 years' experience proves that the protected reservation is an efficient method for increasing the numbers of this grouse without artificial propagation.

The destruction and dispersal of weed seeds by wild birds, W. E. COLLINGE (*Jour. Bd. Agr. [London]*, 20 (1913), No. 1, pp. 15-26).—In order to determine to what extent birds are instrumental in disseminating weed seeds, droppings were collected and placed upon sterilized soil and covered with a little fine soil. One hundred and thirty-three plants representing 7 species developed from 54

droppings of the house sparrow; 52 plants representing 7 species developed from 38 droppings of the greenfinch; and 96 plants representing 9 species developed from 50 droppings of the bullfinch.

In the discussion the author reviews and quotes from the literature on the subject.

The food of some British wild birds, W. E. COLLINGE (*London, 1913, pp. VII+109*).—This work is based upon investigations extending over many years, during which period numerous observations were made in the field and of the stomach contents of upwards of 3,000 adult birds and 300 nestlings. Among the more important subjects dealt with are methods of examination, including observations of the food of nestling birds (E. S. R., 28, p. 450); results of studies of the food of 29 species of birds; birds as destroyers and as distributors of weed seeds, as noted above; birds in relation to forestry; legislation; protective measures; etc.

A bibliography of 114 titles is appended and an index is included.

[Animal pests, etc., in Colorado] (*Off. State Ent. Colo., 1913, Circs. 7, pp. 85, figs. 10; 8, pp. 13, figs. 3; 9, pp. 8, pl. 1, fig. 1*).—Of these circulars (E. S. R., 28, p. 450), No. 7 consists of the Fourth Annual Report of the State Entomologist for the year, 1912, by C. P. Gillette and G. P. Weldon; No. 8, a Report on Prairie Dog Investigations in Colorado, in continuation of work previously noted (E. S. R., 28, p. 652); and No. 9, a discussion of The Wyoming Spermophile or Ground Squirrel (*Citellus elegans*), the last two circulars being by W. L. Burnett. Reports upon the orchard, nursery, nursery stock, and apiary inspection work during the year, and papers on the fruit tree leaf roller in Colorado (E. S. R., 28, p. 450) and upon rodent investigations for 1912 (E. S. R., 28, p. 652) are included in the entomologist's report.

[Notes on insects of economic importance in Germany], K. ESCHERICH and W. BAER (*Naturw. Ztschr. Forst u. Landw., 11 (1913), Nos. 2, pp. 98-109, figs. 3; 3, pp. 121-128, figs. 2; abs. in Rev. Appl. Ent., 1 (1913), Ser. A, No. 10, pp. 371-373*).—These notes relate to the sawfly *Pachynematus montanus* as a new enemy of the pine; the pine as a food of *Lophyrus hercyniæ*; the number of eggs deposited by *Lyda stellata*; injury of *Hepialus humuli* to the hickory (*Carya alba*); the longicorn beetle *Ergates faber* as a pest of pine fence posts, etc.; and a heavy infestation by *Palæococcus fuscipennis*.

Insects injurious to sugar cane in British Guiana, and their natural enemies, G. E. BODKIN (*Jour. Bd. Agr. Brit. Guiana, 7 (1913), No. 1, pp. 29-32*).—This paper lists 32 species of insects injurious to sugar cane in British Guiana and their natural enemies.

Insects attacking the pine, P. LESNE (*Jour. Agr. Prat., n. ser., 25 (1913), Nos. 6, pp. 179-182, pl. 1; 7, pp. 213-215, fig. 1*).—This is a brief account of the more important insect enemies of the pine in France.

Insects and disease, C. WELLMAN (*Amer. Jour. Trop. Diseases and Prev. Med., 1 (1913), No. 5, pp. 346-350*).—A brief discussion with references to the literature.

Infectious diseases and invertebrate transmitters, F. MESNIL (*Bul. Inst. Pasteur, 11 (1913), Nos. 5, pp. 185-196; 6, pp. 233-244*).—This paper presents a list of the invertebrates concerned, and a review of the infectious diseases conveyed by insects and other invertebrates and of the invertebrates and the micro-organisms which they convey. A bibliography of 61 titles is appended.

[Plant inspection in Florida], E. W. BERGER (*Univ. Fla. Off. Insp. Nursery Stock, 1911, Circs. 1, pp. 8; 2, p. 1; 1912, Circs. 3, pp. 15, fig. 1; 4, p. 1; 1913, Circ. 5, pp. 2*).—These circulars relate to the rules and regulations governing plant inspection work in Florida.

East African termites, H. MORSTATT (*Pflanze*, 9 (1913), Nos. 3, pp. 130-141, pls. 3; 9, pp. 443-464, pls. 3).—The first part of this paper consists of a general discussion of termites; the second part relates to the Natal termite (*Termes natalensis*) and other species which attack rubber trees.

The croton bug (*Ectobia germanica*) as a factor in bacterial dissemination, W. B. HERMS and Y. NELSON (*Amer. Jour. Pub. Health*, 3 (1913), No. 9, pp. 929-934, fig. 1).—It is pointed out that the croton bug (*E. germanica*), which feeds by preference upon the food of man, is commonly found in situations where infective sputum or excrement exists, and that it is structurally equipped to collect filth and bacteria upon its appendages, though this equipment is not as effective as in the house fly. It has the ability to pick up bacteria on its feet and mouth parts and deposit these on human food. The bacterial population of a single croton bug was found to be a minimum of 13,370 bacteria.

"The croton bug carries more bacteria upon its hind pair of legs than on its middle and fore legs combined. The croton bug is normally nocturnal in habit though it may be active during the day, and is more or less omnivorous in food habit. The eggs of the roach are laid in pairs (13 pairs usually) in an egg case which is carried for several months by the female. The young roaches require evidently not less than one year to mature and probably more.

"The usual trapping methods are not very effective in the control of the croton bug. Sweet mixtures containing borax or flour and plaster of Paris with water available are recommended as good remedies."

Monograph of the Gryllidæ of Formosa with a review of the Japanese species, T. SHIRAKI (*Monographie der Grylliden von Formosa, mit der Uebersicht der Japanischen Arten. Taihoku, Formosa: Govt., 1911, pp. 129, pls. 2*).—A synopsis of the family in which a large number of species are described as new.

Nine new Thysanoptera from the United States, J. D. HOOD (*Proc. Biol. Soc. Wash.*, 26 (1913), pp. 161-166).—Of the nine species here described as new *Liothrips montanus* from the currant and gooseberry at Bozeman, Mont., is of economic importance.

The thysanopterous cecidia of Java and their inhabitants, H. KARNY and W. and J. VAN LEEUWEN-REIJNVAAN (*Bul. Jard. Bot. Buitenzorg*, 2. ser., 1913, No. 10, pp. 126, figs. 86).—The authors first discuss the cecidia from a botanical standpoint (pp. 1-54), following which they deal (pp. 55-123) with the 47 species and subspecies of thrips concerned, of which 20 forms are described as new.

Froghoppers, J. C. KERSHAW (*Dept. Agr. Trinidad and Tobago Bul.*, 12 (1913), No. 72, pp. 3-12, pls. 3).—These miscellaneous notes make up Special Circulars 3 to 7.

The vermilion egg parasite of the froghopper has not been reared in captivity during the dry season in sufficient numbers to give any great encouragement that it will check the froghopper. In addition to the use of the green muscardine fungus, which has given good results in the past and is now being used on a large scale, the author suggests 3 other means of combating the pest, (1) the application of nitrolim (calcium cyanamid); (2) kerosene-lysol emulsion (lysol 3 oz., kerosene 9 oz., and water 4 gal.); and (3) the removal and destruction of dry leaves on which the eggs may have been deposited. The notes include a discussion of the male genital armature of *Tomaspis*.

The sugar cane froghopper and biological notes on some cercopids of Trinidad, F. W. URICH (*Dept. Agr. Trinidad and Tobago Bul.*, 12 (1913), No. 72, pp. 12-51, pls. 7, figs. 9).—This report reviews records of froghoppers in other countries; gives a discussion of the origin and distribution of the sugar cane froghopper, its life history and habits, natural enemies, and artificial

control; and biological notes on *Tomaspis rubra sororia*, *T. pubescens*, *T. guppyi* n. sp., *T. postica*, and *Clastoptera lanata*.

[Froghoppers in Trinidad], J. C. KERSHAW ET AL. (*Dept. Agr. Trinidad and Tobago Bul.*, 12 (1913), No. 73, pp. 95-106, pls. 2, figs. 12).—These notes relate to mating, oviposition, estivation of eggs, manner in which the froghopper feeds, the green muscardine fungus, etc.

Rearing of the vermilion froghopper egg parasite, F. W. URICH (*Bd. Agr. Trinidad and Tobago, Circ.* 7, 1913, pp. 7; *abs. in Rev. Appl. Ent.*, 1 (1913), *Ser. A*, No. 4, pp. 116, 117).—The methods employed in rearing the egg parasite of this froghopper in Trinidad are described.

The froghopper egg parasite (*Oligosita giraulti*) and its colonization in the cane fields, F. W. URICH (*Bd. Agr. Trinidad and Tobago, Circ.* 11, 1913, pp. 9).—This paper presents additional data on the froghopper egg parasite, which has been described by Crawford as *O. giraulti*. It embodies the results of rearings of the parasite under laboratory conditions from February to June, including notes on its life history, habits of the adult parasite, multiplication, etc.

On a remarkable gall-producing psyllid from Syria, R. NEWSTEAD and B. F. CUMMINGS (*Ann. and Mag. Nat. Hist.*, 8, ser., 11 (1913), No. 63, pp. 306-308, pl. 1, fig. 1).—The author describes a pod-shaped gall, found some 8 miles from Beyrout on a twig of what is thought to be a tamarind, and the larvæ and pupæ of a species of psyllid belonging to the subfamily Trioziinæ, which it contained.

The rosy apple aphid (*Aphis sorbi*), serious pest, H. F. WILSON (*Better Fruit*, 7 (1913), No. 12, pp. 17, 18).—This aphid is said to be by far the most serious plant louse attacking fruit trees in Oregon. The species, a native of Europe, probably imported to this country on nursery stock, has now spread to most of the apple-growing sections of the United States, and is said to be generally distributed in Oregon.

In this paper the author reports studies of its life history and habits so far as determined during 2 seasons' work. The winter is passed in the egg stage, the stem mothers hatching out just as the buds begin to open in the spring. The aphids usually attack the leaves surrounding the fruit clusters, but in years when the crop is light may be found almost anywhere on the leaves. Their attacks result in the production of deformed apples, this apparently being due to the extra supply of juices drawn into the leaves and absorbed by the aphids. Unlike the green apple aphid this species seldom attacks the young growing shoots.

In experiments conducted during the spring of 1911 applications of blackleaf 40 and of blackleaf 40 combined with lime-sulphur have been found to be efficient, but lime-sulphur (1:10) alone failed to have any effect upon the aphids. It is stated that spray thoroughly applied at the time the buds are commencing to open will prevent from 95 to 100 per cent of aphid infestation.

Report on the distribution of the grape phylloxera (*Phylloxera vastatrix*) in Austria in 1910, 1911, and 1912, as well as on the work and results secured in reestablishing infested vineyards, together with the laws, orders, and exemptions dealing with the phylloxera (*Ber. Verbr. Reblaus Österr.*, 1910-1912, pp. 332, pl. 1).—This report, which covers the various grape growing centers of Austria, is in continuation of the report previously noted (E. S. R., 25, p. 341).

The beet plant louse in northern France, A. MALAQUIN and A. MOITIFÉ (*Vie Agr. et Rurale*, 2 (1913), No. 24, pp. 696-699, figs. 7; *abs. in Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 7, p. 1125).—*Aphis papaveris* has appeared in large numbers in northern France during the

last few years, especially in 1911, and has been a source of considerable damage to beets. The authors confirm the observations of Mordwilko, who considers this species to be the same as that found on *Euonymus europæus* in spring and known as *A. euonymi*.

Notes on coccids which attack the coconut palm and other plants cultivated on a large scale in Mahé, Seychelles, P. R. DUPONT (*Abs. in Rev. Appl. Ent.*, 1 (1913), Ser. A, No. 4, pp. 129, 130).—Seven species of *Lecanium* are mentioned as occurring in the Seychelles. A species of fungus of the genus *Hypocrella* is said to attack these scales; a species of *Microcera* attacks *Diaspis pentagona*, which injures the leaves of plum trees and the trunks of papaws; and *Cephalosporium lecanii* parasitizes *Lecanium viride*, which has caused the disappearance of almost all the thorn-bearing trees in the Colony.

Some field notes on a soft gray scale known locally as the "longulus" scale, D. KELL (*Mo. Bul. Com. Hort. Cal.*, 2 (1913), No. 8, pp. 617-619).—Biologic notes and a brief report in tabular form upon experimental fumigation work are given. See also a previous note (E. S. R., 28, p. 452). The results indicate that there is a good chance of obtaining a fairly high destruction of this scale by fumigating between July 20 and the end of August.

The tobacco caterpillar (*Prodenia litura*), C. R. JONES (*Philippine Agr. Rev. [English Ed.]*, 6 (1913), No. 9, pp. 425-432, pl. 1, figs. 2).—This noctuid is said to be the greatest pest of tobacco in the Philippines, the larvæ attacking growing tobacco, both young and old, but causing the greatest damage to the young leaves. This paper presents an account of its life history and habits with remedial measures.

The cotton worm in Egypt, G. C. DUDGEON (*Bul. Imp. Inst. [So. Kensington]*, 10 (1912), No. 4, pp. 584-620, pl. 1, fig. 1).—A summarized account of *Prodenia litura* (*litoralis*) including its synonymy, distribution, life history, control, etc.

Recent work on the polyhedral body disease of caterpillars, K. ESCHERICH (*Naturw. Ztschr. Forst u. Landw.*, 11 (1913), No. 2, pp. 86-97, fig. 1).—This is a critical review of recent literature on the wilt disease of caterpillars.

The rice caterpillar (*Laphygma frugiperda*), G. E. BODKIN (*Jour. Bd. Agr. Brit. Guiana*, 6 (1913), No. 4, pp. 172-183).—In British Guiana the fall army worm is an extraordinarily destructive pest, occurring in countless numbers in the young rice nurseries when the plant is at the most critical stage of its growth. If control measures are not immediately taken it destroys the entire nursery in a short time. In this paper the author deals with its distribution, life history, natural enemies, and means of control.

A serious Philippine orange moth (*Prays citri*), E. O. ESSIG (*Mo. Bul. Com. Hort. Cal.*, 2 (1913), No. 11, pp. 722, 723, fig. 1).—The larvæ of this pest is said to live just beneath the rind next to but not in the pulp of the cajel, a variety of the native orange, and to produce gall-like swellings which remain opened at the outside but do not seem to penetrate the pulp at all.

A pest of oranges (*Agr. News [Barbados]*, 12 (1913), No. 302, p. 378).—A small moth, apparently a tortricid, is reported to have become a pest of oranges in Dominica through penetrating the skin and living and feeding in the pulp.

The gunworm of the grape (*Sciopteron regale*), F. MASKEW (*Mo. Bul. Com. Hort. Cal.*, 2 (1913), No. 10, pp. 677-679, figs. 2).—This paper presents descriptions of the stages of a lepidopteran reared from grape twigs collected in the Orient and intercepted at quarantine.

The transmission of verruga by *Phlebotomus*, C. H. T. TOWNSEND (*Jour. Amer. Med. Assoc.*, 61 (1913), No. 19, pp. 1717, 1718).—The author reports the results of a preliminary transmission experiment in which 2 hairless dogs of the species *Canis caraibicus* were used. One cc. of serum containing the triturated bodies of 20 females of *Phlebotomus verrucarum*, a biting gnat occurring in

the verruga zones of the Peruvian Andes, was injected in the right shoulder of one of the dogs, the other dog being reserved as a check. The symptoms resulting showed the disease to have been transmitted to the injected dog, while the check animal showed nothing abnormal.

This is said to be the first experimental demonstration of insect transmission of the disease.

The gall midge fauna of New England, E. P. FELT (*Psyche*, 20 (1913), No. 5, pp. 133-147).—Of some 900 species of gall midges known from America, the author lists 137 as occurring in the New England States.

The box cecidomyiid (*Monarthropalpus buxi*), J. CHAINE (*Ann. Sci. Nat. Zool.*, 9. ser., 17 (1913), No. 5-6, pp. 269-359, pls. 3, figs. 26).—This paper relates to the morphology, biology, injury, and remedial measures for this cecidomyiid, which burrows in the leaves of the box (*Buxus sempervirens*).

The life history of *Thrypticus mühlenbergiae* n. sp., O. A. JOHANNSEN and C. R. CROSBY (*Psyche*, 20 (1913), No. 5, pp. 164-166, fig. 1).—The larva of this dipteran lives in the stems of *Muhlenbergia sylvatica* in the vicinity of Ithaca, N. Y.

The biology of *Tabanus striatus*, the horsefly of the Philippines, M. B. MITZMAIN (*Philippine Jour. Sci.*, Sect. B, 8 (1913), No. 3, pp. 197-221, pls. 7).—"The eggs of *T. striatus* have been found in masses of from 270 to 425, laid mainly on particles of wood. The incubation period has been determined to be from 3 to 5 days. The behavior of the larva indicates that it is essentially an aquatic form. The insect in this stage has been found to be extremely cannibalistic. In some instances as high as 85 per cent of the brood has been destroyed by this means. They apparently prefer their kind to any other food; at least there is no diminution of the practice even when an abundance of other food is present. There is shown to be a marked diversity in the development of larvæ of the same age. The larval period covers 6 weeks or longer.

"In the ecdyses of *T. striatus* there are 3 distinct molts; the final one, coming a considerable time after the larva is full grown, results in the unveiling of the puparium. The puparium is formed beneath the molting skin of the full-grown larva. This stage lasts from 3 to 7 days, with an average of 5½ days, in the male; and from 4 to 9 days, with an average of 6 days, in the female. In this period the male can be distinguished by the arrangement of the short spines anterior to the terminal teeth of the abdomen. These form a continuous serrated border of from 10 to 12 short spines. In the female these spines occur in 2 groups of from 4 to 6 each. Evidence of development of the adult fly is had in the changes of coloration visible through the puparium. . . . In from 14 to 20 minutes after emergence the imago takes flight. . . .

"All of the draft animals of the Philippines serve as hosts for *T. striatus*. The carabao appears to be the host of choice. The rain trees of this locality serve to harbor great numbers of resting horseflies. In considering methods of eradication, this fact should be considered."

The mechanical transmission of surra by *Tabanus striatus*, M. B. MITZMAIN (*Philippine Jour. Sci.*, Sect. B, 8 (1913), No. 3, pp. 223-229; *Philippine Bur. Agr. Bul.* 28 1913, pp. 11).—"T. *striatus* for the first time recorded has been found to play a rôle in the transmission of surra. Bred horseflies have been employed for the first time in such experiments. Errors resulting from naturally infected wild flies have thus been eliminated. Three experiments were successful in the direct or mechanical transmission by 'interrupted' feeding when only a short interval was allowed between the bites on infected and healthy animals. In 16 experiments the minimum number of flies with which the infection could be transmitted was 2.

"Trypanosomes of surra were not found to be transmitted hereditarily in *T. striatus* Fabricius. The contaminated labellum of the fly does not appear to be a factor in the conveyance of infection. The maximum length of time that *Trypanosoma evansi* has been demonstrated microscopically in the gut of this species of fly after feeding on infected blood is 30 hours; the organisms were found in the fly's dejecta 2½ hours after biting the infected animal; and suspensions of flies, when injected subcutaneously, were found infective for animals for a period of 10 hours after the flies had fed on infected blood."

Stages in life history of warbles, C. VANEY (*Abs. in Jour. Roy. Micros. Soc. [London], 1913, No. 5, p. 480*).—The author distinguishes 4 larval stages in species of Hypoderma, (1) the boring larva which emerges from the egg, traverses the mucous membrane of the alimentary canal, and lodges in the submucosa; (2) the migratory larva which develops in great part in the submucosa of the gullet, migrates in the connective tissue to the subcutaneous tissue, and finally perforates the dermis; (3) a short third stage, sedentary in the skin, and breathing atmospheric air; and (4) the final stage, which lasts for 3 months and is sedentary until the host is left.

It is concluded that all the facts regarding *H. bovis* confirm the theory of Hinrichsen and Curtice that the parasite enters cattle by the alimentary tract exclusively.

Flies as carriers of *Lambliia* spores.—The contamination of food with human excreta, C. W. STILES and W. S. KEISTER (*Pub. Health Rpts. [U. S.], 28 (1913), No. 48, pp. 2530-2534*).—The authors present evidence to show that the house fly is capable of carrying *Lambliia* spores. "If flies can carry *Lambliia* spores measuring 10 by 7μ, and bacteria that are much smaller, and particles of lime that are much larger, there is no ground to assume that flies may not carry *Entamoeba* and *Trichomonas* spores."

Flies and disease in the British army, S. WESTCOTT (*Jour. State Med., 21 (1913), No. 8, pp. 480-488*).—This general account includes observations made by the author.

Control measures for the olive fly, CHAPELLE (*Bul. Mens. Off. Renseig. Agr. [Paris], 11 (1912), No. 12, pp. 1703-1707*).—This is a summary of the results of observations and experiments by the Oleaculture Service in France during 1912.

The Anthomyidæ, J. SCHNABL and H. DZIEDZICKI (*Abhandl. K. Leopold. Carolin. Deut. Akad. Naturf., 95 (1911), No. 2, pp. 55-358, pls. 35*).—A revision of the family Anthomyidæ taken in its widest sense. Special consideration is given to the male genitalia, the plates consisting of drawings of the hypopygia. Descriptions of a large number of new species are included.

A synopsis of the dipterous groups Agromyzinæ, Milichiinæ, Ochthophilinæ, and Geomyzinæ, A. L. MELANDER (*Jour. N. Y. Ent. Soc., 21 (1913), No. 4, pp. 283-300, pl. 1*).—A continuation of the paper previously noted (*E. S. R., 29, p. 657*).

The importance of the rat flea in determining the distribution of bubonic plague, S. KITASATO (*Berlin. Klin. Wchnschr., 50 (1913), No. 41, pp. 1881-1884; abs. in Jour. Amer. Med. Assoc., 61 (1913), No. 21, p. 1939*).—The author confirms the efficacy of the method of collecting rat fleas by turning guinea pigs loose in the infected buildings. During the course of work at Kobe in 1909-10 guinea pigs collected infected fleas in 11 of 42 houses supposed to have been thoroughly disinfected after cases of plague, thus proving that the disinfection had not been complete. One hundred and twenty-two guinea pigs which were turned loose in 36 other houses from which rats had been exterminated and the buildings made absolutely rat proof collected but one flea and no signs of infection were found.

The western twig borer (*Amphicerus punctipennis*), E. O. ESSIG (*Mo. Bul. Com. Hort. Cal.*, 2 (1913), No. 10, pp. 681-684, figs. 3).—A brief summarized account of this coleopterous borer, which attacks the algaroba (*Prosopis juliflora*), apricot, pear, etc.

Two ladybirds injurious to potato plants, R. W. JACK (*Rhodesia Agr. Jour.*, 11 (1913), No. 1, pp. 77-82, pl. 1).—The author states that two species of *Epilachna* (*E. dregci* and *E. hirta*), which normally feed on certain wild species of solanaceous plants in Southern Rhodesia, have developed a taste for the potato and are a common source of injury.

Psylliodes attenuata, the hop or hemp flea beetle (*Verhandl. K. K. Zool. Bot. Gesell. Wien*, 63 (1913), Nos. 1-2, pp. 1-25, figs. 15; 3-4, pp. 98-136, figs. 20).—This paper consists of 2 parts. The first by F. Tölg deals with the morphology and biology of the immature stages; the second by F. Heikertinger with the imago, including injury and preventive measures.

The Mexican cotton boll weevil (*Anthonomus grandis*), E. W. BERGER (*Univ. Fla., Off. Insp. Nursery Stock, Circ.* 6, 1913, pp. 24, pls. 7, figs. 4).—A general account of the boll weevil, including means of control.

Utilization of entomophagous parasites in combating disease conveying insects, E. BRUMPT (*Abs. in Ann. Méd. Vét.*, 62 (1913), No. 7, pp. 402-410).—In discussing the importance of *Ixodiphagus caucurtei*, a parasite of ticks recently described as new (E. S. R., 27, p. 564), the author states that he has met with considerable success in the experimental infestation of several species of ticks. At Chantilly, Department of Oise, as high as 17 per cent of the nymphs of *Ixodes ricinus* on deer were found to be parasitized by it, and at Fontainebleau under similar conditions as high as 10 per cent. At the latter place two nymphs of *Hæmaphysalis concinna* were also discovered to be parasitized. Experimentally he succeeded in parasitizing 95 per cent of *I. ricinus*, 90 per cent of *Dermacentor reticulatus*, 90 per cent of *Rhipicephalus sanguineus*, and 100 per cent of *D. venustus*.

Notes on the biology of this parasite, of which the author has reared four successive generations in five months, are included.

The life history and habits of *Spalangia muscidarum*, a parasite of the stable fly, H. PINKUS (*Psyche*, 20 (1913), No. 5, pp. 148-158, pl. 1, fig. 1).—It is stated that the adults of this parasite, recently described as new (E. S. R., 29, p. 359), are scavengers from habit, preferring to feed on the remains of the host, and that it is not necessary to furnish prepared food in rearing cages. It is said to be a simple parasite, and does not usually deposit a second time in a single host. In addition to the stable fly, the house fly, horn fly, *Helicobia quadrisetosa*, and *Pseudopyrellia cornicina* have been parasitized experimentally. That the stable fly is the principal host of this parasite appears to be due to its breeding habits. Breeding is said to progress well at 70° F. and somewhat higher temperatures. The adults become inactive at from 55 to 60°.

It is possible to propagate these parasites artificially in large numbers throughout the winter and liberate them early in the spring. By this means the first generation of flies may be cut down to a great extent, and this aids in the control of the flies throughout the year.

A breeding cage, modeled by the author and found to be quite practical for the breeding of this parasite, is described and illustrated.

Descriptions of ten new genera and twenty-three new species of ichneumon flies, H. L. VIERECK (*Proc. U. S. Nat. Mus.*, 44 (1913), pp. 555-568).—Among the more important species described as new are *Apanteles laspeyresiae*, reared from *Laspeyresia torenta* on *Pinus ponderosa* at Shasta, Cal.; *A. phycodis*, a parasite of *Phycodes radiata*, and *A. plusiæ*, a parasite on *Plusia agamma*, both at

Bangalore, India; *Meteorus laphygmae*, reared from the fall army worm at Brownsville, Tex., and which may prove to be only a race or variety of *M. hyphantriae*; *Perilitus eleodis*, reared from *Eleodus suturalis* at Argonia, Kans.; *A. congregatus*, reared from *Ceratonia catalpæ* at Greenville, S. C.; *A. empretiæ*, reared from (*Empretia*) *Sibine stimulea* at Washington, D. C.; *Opius anastrephæ*, reared from *Anastrepha* sp. at Mayaguez, Porto Rico; *Enicospilus heliothidis*, a parasite of *Heliothis obsoleta*, at Deli, Sumatra; *Mesochorus plusiæphilus*, which is a hyperparasite and probably parasitic on *Apanteles plusiæ* or on a *Meteorus*, at Bangalore, India; *Pezomachus perniciosus*, reared from cocoons of *Meteorus laphygmae* at Brownsville, Tex.; *Phygadeuon epochræ*, a parasite on *Epochra canadensis* at Bozeman, Mont.; etc.

Descriptions of six new genera and twelve new species of ichneumon flies, H. L. VIERECK (*Proc. U. S. Nat. Mus.*, 44 (1913), pp. 639-648).—The new species include two fruit fly parasites from India, namely, *Asobara orientalis* n. sp. and *Diachasmimorpha comperei* n. g. and n. sp.

Another red species of the genus *Oligosita*, J. C. CRAWFORD (*Canad. Ent.*, 45 (1913), No. 9, pp. 311, 312).—A parasite reared from the eggs of *Tomaspis varia* in Trinidad is described as *Oligosita giraulti* n. sp.

The egg parasite of the small sugar-cane borer, G. E. BODKIN (*Jour. Bd. Agr. Brit. Guiana*, 6 (1913), No. 4, pp. 188-198, pls. 4).—A species of *Trichogramma*, closely related to *T. pretiosa* and *Chætosicha nana*, is deemed the most effective of the several parasitic enemies of *Diatræa saccharalis* in British Guiana. In the present paper the author deals with its life history and habits.

As many as 5 parasites may develop in a single egg of the sugar-cane borer, 3 being an average number. The author confirms previous observations, which show that the female *Trichogramma* is capable of producing a parthenogenetic generation, the progeny invariably being males. Eighty adults which developed from 100 ovipositions was the maximum number of parasites produced by a single female.

Introduction to the study of the myriapods, C. E. PORTER (*Introduccion al Estudio de los Miriápodos. Santiago, Chili, 1911, pp. 68, figs. 22*).—This is an illustrated account of the morphology, biology, classification, and economic importance of myriapods. It includes a list of the 64 species described from Chili and a bibliography of the more important literature.

FOODS—HUMAN NUTRITION.

The meat supply of the German Empire—an investigation of the causes and effects of the increased cost of meat and means of overcoming it, J. B. ESSLEN (*Die Fleischversorgung des Deutschen Reiches. Eine Untersuchung der Ursachen und Wirkungen der Fleishteuerung und der Mittel zur Abhilfe. Stuttgart, 1912, pp. 224; rev. in Ztschr. Agrarpolitik, 11 (1913), No. 10, p. 322*).—As the subtitle indicates, this book is a study of the conditions leading to the increased cost of meat in Germany and of means of increasing the supply so that the per capita consumption need not fall below the Voit dietary standard. The reduction of duties on cereals as a means of encouraging home production of meat, and the dependence of Germany on Argentina for meat in case of war, are among the topics discussed.

The price of meat in Paris, P. VINCEY (*Le Prix de la Viande. Paris, 1912, pp. 151, pls. 6, figs. 57*).—This book, privately printed, gives the results of a study of meat prices as shown in the official market reports of the Prefecture of the Seine and of the Police. The three points especially investigated were, the variations in the wholesale and retail prices of meat; the rise in price brought about by the retail sale of meat in small city shops; and the distribution among

producers and intermediaries of the proceeds of the sale of meat products in Paris.

The author estimates that of the price paid by the retail buyer, 76 per cent goes to the original producer, while, of the remaining 24 per cent, 2 per cent goes to the railways, 1 per cent to the cattle commissioners, 5 per cent to the city of Paris (for duties, slaughterhouse fees, market facilities, etc.), 3 per cent to the wholesale dealers, and 13 per cent to the retail dealers.

The appendix includes plates showing the method of cutting meats and the names of cuts in vogue in the Parisian markets.

The red color developed when meat is boiled in water, KLUT (*Mitt. K. Landesanst. Wasserhyg. Berlin-Dahlem*, 1913, No. 17, pp. 36-39; *abs. in Chem. Zentbl.*, 1913, II, No. 13, p. 1162).—The red color was noted in meat cooked in soft to medium hard water flowing from zinc-coated pipes and containing variable quantities of free carbon dioxid and occasionally very small quantities of nitrates.

The experiments showed that the presence of minute quantities of N_2O_3 in the water was sufficient to cause a red color and explained the observed red color in boiled meat as due to the presence of minute quantities of N_2O_3 produced by the reduction of nitrates by zinc in the presence of free carbon dioxid. The author recommends that water which has stood in the pipes for a long time should not be used for cooking purpose but allowed to run for a time before using.

The Tellier method of preserving dried meat, LALLIÉ (*Deut. Schlacht u. Viehhof Ztg.*, 13 (1913), No. 43, pp. 655, 656).—In this summary of an article in *La Nature* a method of preserving meat is described which consists essentially of drying it in vacuum until about 20 per cent of the water is removed, which requires from about 12 to 24 hours. The process is said to be inexpensive, while the nutritive value and culinary quality of the meat are unchanged.

The author states that such partially dried meat keeps well under ordinary conditions.

Seasonings and bouillon cubes, K. MICKO (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 26 (1913), No. 7, pp. 321-339).—Analytical data are reported and discussed.

The chemical composition of rye and its milling products—the distribution of the materials in the grain, M. P. NEUMANN, H. KALNING, ET AL. (*Ztschr. Gesam. Getreidew.*, 5 (1913), No. 2, pp. 41-50).—Determinations were made of the composition of specially selected typical samples of the whole grain and the various milling products of rye. The proportions of soluble to insoluble protein and of various sugars and pentosans to the total starch, nonnitrogenous extractives, crude fiber, phosphoric acid, etc., found in the different milling products are noted in detail.

The chemical composition of wheat and its milling products—the distribution of the materials in the grain, H. KALNING and A. SCHLEIMER (*Ztschr. Gesam. Getreidew.*, 5 (1913), No. 7, pp. 199-207).—This work is carried out on the same lines as that of Neumann on rye, noted above.

The authors suggest the importance of a more extended knowledge of the various milling products for the sake not only of making technical improvements in the milling processes, but also of a better understanding of nutritive value. The significance of ferments in the grain during both storage and bread making is also indicated.

The bread making qualities of domestic [German] and foreign wheats, M. P. NEUMANN (*Ztschr. Gesam. Getreidew.*, 5 (1913), No. 8, pp. 223-229, figs. 11).—Bread making tests were made to determine the behavior of characteristic mixtures of German and foreign wheats. In general, the addition of the hard foreign wheats increased the bread making qualities of the domestic flour.

Indian edible swallows' nests, H. ZELLER (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 86 (1913), No. 2, pp. 85-106).—Analytical data are reported, particularly with reference to the nitrogenous constituents present.

Grecian honey and wax, E. I. EMMANOUËL (*Ber. Deut. Pharm. Gesell.*, 23 (1913), No. 6, pp. 395-410; *abs. in Chem. Zentbl.*, 1913, II, No. 14, p. 1249).—This article reports in a more accessible form material previously published in Greek (*E. S. R.*, 28, p. 862). (In this note the author's name was incorrectly spelled.)

The manufacture of chocolate, R. VALLIER (*Rev. Gén. Chim.*, 15 (1912), No. 12, pp. 213-223, *figs.* 8).—This article, which is illustrated with cuts of machinery, deals with the raw materials utilized in the manufacture of chocolate, the usual methods for manufacturing this commodity, the manufacture of soluble cocoa and various other specialties, and the amount of chocolate consumed in various countries. In 1905 the United States consumed the largest quantity of these products.

Modern fruit ethers, E. WALTER (*Pure Products*, 9 (1913), No. 11, pp. 543-549).—The character and uses of fruit ethers are discussed and formulas are given for making "the most commonly used [artificial] fruit ethers."

[Inspection of foods, dairy products, and feeding stuffs], W. D. SAUNDERS ET AL. (*Quart. Rpt. Dairy and Food Comr. Va.*, 1913, June-Aug., pp. 60).—Data regarding the analysis of miscellaneous samples of foods and beverages, inspection work, and other activities are reported.

Extracts from the report of the inspection service, etc., C. H. KETNER (*Chem. Weekbl.*, 10 (1913), No. 37, pp. 806-812).—This article is taken from official reports for the year 1912 regarding the examination of foods and other materials as conducted by the Office of Public Health in Holland. The subjects mentioned include milk, bread, Rangoon beans, lemonade sirups, jams, saccharin, preservatives, distilled liquors, etc.

The adulteration of sugar products as defined by Italian legislation, L. GABELLI (*Ann. R. Accad. Agr. Torino*, 55 (1912), pp. 255-292).—A discussion of Italian laws, municipal regulations, etc., relating to the adulteration of foods made with sugar.

Scientific standards for the governmental regulation of foods, J. R. MURLIN (*Pop. Sci. Mo.*, 83 (1913), No. 4, pp. 344-354).—A plea that the scope of governmental control over food materials be so extended as to make it necessary for all those offered for sale to bear on their labels their energy value and percentage of protein.

What the Department of Agriculture is doing for the housewife, A. D. HOLMES (*Alumni Bul. Univ. Va.*, 3. ser., 6 (1913), No. 4, pp. 546-554).—The activities of the Department which are of interest to the housewife, particularly the nutrition investigations of the Office of Experiment Stations, are discussed in this address, which was delivered before the Rural Life Conference, University of Virginia, July, 1913.

Division of labor between country and city in the production of animal food materials as an aid to the regulation of the cost of living, F. FALKE (*Mitt. Ökonom. Gesell. Sachsen*, 1912-13, pp. 167-197, *figs.* 11).—This address, delivered before the Saxon Society of Economics, February, 1913, gives a description and discussion of the cooperation which has been successfully organized between a rural association of hog breeders and the cities of Ulm and New Ulm (Bavaria).

The breeders' association agreed to furnish a given number of hogs of given average weight at a fixed price. The 2 cities provided land and buildings for a fattening station, made a loan to the association for the feed used in fattening, and regulated the sale of the fattened animals in the

2 cities. The hogs thus supplied furnished about one-seventh of the amount annually consumed and were regularly distributed in different districts by arrangements with the butchers' associations and retailed at a price below the prevailing one. The profits to both dealers and breeders are considered just, though the latter naturally varied with the price of feed.

Retail prices, 1890 to June, 1913, F. C. CROXTON (*U. S. Dept. Labor, Bur. Labor Statis. Bul. 132, 1913, pp. 134*).—This publication, which is No. 10 of the Retail Prices and Cost of Living Series, contains a summary of data regarding retail prices of food in different States in the United States from 1890 to June, 1913.

Data are also given regarding the scaling weight (i. e., weight of dough before baking) as well as the prices of the principal brands of baker's wheat bread as reported by representative bakeries, and some statistics regarding the cost of coal and gas.

[Storage and the housekeeper's problems] (*Proc. Amer. Warehousemen's Assoc., 21 (1911), pp. 160-163, 232-258, pls. 2, figs. 2*).—Among the papers presented at the annual meeting held in Chicago in December, 1911, several are of interest to housekeepers, namely: Cold Storage for Household and Personal Effects, by Aspinwall; Economic Results of Cold Storage, by G. K. Holmes; and Effects of Temperature on Changes in the Flesh of Poultry, by Mary E. Pennington.

Exhibiting, classifying, and judging homemade products, J. B. S. NORTON (*Hyattsville, Md., 1913, pp. 32*).—This pamphlet, which was prepared while the author was in charge of the home products exhibit of the Maryland Horticultural Society, discusses the management of exhibits and related topics, awards, and rules for judging, and gives some directions regarding the preparation of fruit products and a collection of score cards for canned fruits, jellies, preserves, and other fruit products.

The economy administration cook book, edited by SUSIE R. RHODES and GRACE P. HOPKINS (*Hammond, Ind., 1913, pp. 696, pls. 46*).—It has been the purpose, in collecting material for this volume, to include recipes for inexpensive dishes and to present other data which would aid the housewife in economical as well as good living. The recipes have been contributed by a very large number, including many women of prominence. A considerable number are quoted from the Wilson Family Cook Book. Many menus are included, as well as discussions of preparing and preserving food and other topics, such as an expensive and an inexpensive luncheon regarded as equally attractive and palatable and of practically the same nutritive value, by Mrs. T. R. Marshall, home luncheons and lunch box combinations, by Emma S. Jacobs, and a list of articles which should be served with the proper items in a menu.

The twentieth century book for the progressive baker, hotel confectioner, ornamenteer, and ice cream maker, F. L. GIENANDT (*Boston, 1913, 2. ed., pp. 274, pls. 58, figs. 127*).—This volume, which consists largely of recipes and directions for the preparation of food, is designed especially for the use of bakers and professional cooks. The author has summarized his experience in various matters, among others the use of powdered milk, which he has found in general to be satisfactory.

Diet in health and disease, J. FRIEDENWALD and J. RUHRÄH (*Philadelphia and London, 1913, 4. ed., rev. and enl., pp. 857+16*).—The authors state that in preparing this edition (*E. S. R., 17, p. 579*) several new sections have been added, including those dealing with the mechanism of digestion, salt metabolism, duodenal alimentation, and the use of the soy bean, while other sections have been revised, including those on metabolism and the prescribing of diet, infant feeding, and several sections dealing with diet in disease. New tabular

matter and diet lists have been prepared and other changes made. These and other matters are discussed at some length in the preface to this edition.

The child—its care, diet, and common ills, E. M. SILL (*New York, 1913, pp. VIII+207, figs. 34*).—A brief but fairly complete guide in the intelligent care of infants and small children. The 40 or more pages devoted to feeding outline the general principles regarding the diet of children and give definite practical suggestions as to their application. The relation of diet to the more common disorders of childhood is also noted.

The proper diet in the Tropics, with some pertinent remarks on the use of alcohol, A. C. EUSTIS (*Amer. Jour. Trop. Diseases and Prev. Med., 1 (1913), No. 4, pp. 288-293*).—The author holds that there is greater danger from an excessive use of meat in tropical than in temperate regions, because "ptomaines", which may be produced from undigested meat by the action of putrefactive bacteria in the colon, and which under ordinary conditions would be "rendered inert by the liver cells", would not, in his opinion, be so taken care of where there is little severe exercise, as is the case with most residents in warm regions.

He believes further that in such regions "there is little need of internal combustion to maintain the body temperature."

Similar arguments are given against the use of alcohol.

In the author's opinion, not more than 40 gm. of protein per day should be eaten in the Tropics. He believes that the energy value of the daily diet should be from 2,000 to 2,500 calories, depending upon the muscular work done, fats being taken in moderation and the energy supplied largely from carbohydrates; that vegetable proteids are preferable to animal proteids; and that the diet should contain an abundance of fruits and vegetables.

The desirability of limiting the amount of meat in the diet is illustrated by a case cited in which symptoms of toxemia in a patient were overcome by reducing the meat consumption and which the author considers typical of many which he states have come under his observation.

Meat feeding experiments with mice and their value as a means of determining the harmfulness of suspected meat upon the health, R. REINHARDT and E. SEIBOLD (*Ztschr. Infektionskrank. u. Hyg. Haustiere, 12 (1912), No. 4, pp. 332-350*).—The literature relating to feeding experiments with diseased meats is reviewed and the results are given of a series of experiments in which white mice were fed upon meat which had been infected in some instances with *Bacillus paratyphosus* and in others with *B. enteriditis*, the infections having undergone various stages of development.

From the results of these experiments, the authors conclude that white mice are not suitable subjects for such experiments and that neither positive nor negative results of the feeding of suspected meat to white mice will permit the drawing of conclusions relative to the fitness for human food of the meat in question.

Creatin and creatinin in total and partial fasting, V. SCAFFIDI (*Arch. Ital. Biol., 59 (1913), No. 2, pp. 161-172*).—Studies were made of creatin and creatinin and of total nitrogen exchange in feeding laboratory animals (dogs) on a mixed diet, in total fasting, and in a diet in which the nitrogen was replaced by fats.

During fasting a variable quantity of creatin appeared in the urine, while under normal conditions of nitrogen equilibrium little or none was found. The quantity of nitrogen eliminated in these experiments and derived from the combustion of tissue was greater than that eliminated during maintenance upon a mixed diet sufficient to maintain body weight. More creatinin was elimi-

nated than under normal conditions. The percentage of creatinin nitrogen decreased with the increase of total nitrogen; consequently, the elimination of this substance is not proportional to the total nitrogen. If, however, creatin nitrogen be considered as creatinin nitrogen, the total of such nitrogen is nearly that of the normal percentage of creatinin nitrogen.

When the nitrogen of the normal mixed diet is replaced with fat, the organism tends to retain nitrogen which is eliminated in smaller proportions than in mixed feeding or in total fasting. The quantity of creatinin eliminated is also smaller, but the appearance of small quantities of creatin is not prevented. The daily percentages of creatin nitrogen and creatinin nitrogen vary less than in complete fasting. There appears to be a relation between endogenous nitrogen and creatin and creatinin. Therefore, the quantity of creatin eliminated is not proportional to the amount of nitrogen ingested.

Purin metabolism with diminution of the processes of oxidation in the organism, V. SCAFFIDI (*Arch. Ital. Biol.*, 59 (1913), No. 2, pp. 172-179).—The experiments here noted were made with 2 types of laboratory animals, those (dogs) in which the uric acid eliminated is the result of oxidation and those (ducks) in which it is of synthetic origin. In both groups, the animals were previously kept on a purin-free diet and then made to inhale air containing different amounts of carbon dioxide and oxygen.

When the conditions determining a temporary variation in the processes of oxidation had thus been controlled, it was found that they had no influence on the uric acid metabolism of the dogs. In the experiments with ducks, however, temporarily limiting the oxidation of the tissues caused an increased formation of uric acid. This fact is to be explained by assuming either that the slight uricolytic power of the ducks is lessened by the conditions of the experiment or that the synthesis of uric acid is facilitated by the products of the breaking down of the protein molecule.

Purin metabolism during fasting, V. SCAFFIDI (*Arch. Ital. Biol.*, 59 (1913), No. 2, pp. 180-192).—Ducks and dogs were used in these experiments as types of animals in which the uric acid eliminated was formed by synthesis and oxidation, respectively.

In the case of ducks, the author concludes that the uric acid eliminated represents from 42 to 53 per cent of the total nitrogen metabolism. During fasting and overfeeding it follows closely the variations of total nitrogen. The proportion of total to uric nitrogen rose during high feeding and fell during complete fasting.

In the case of dogs, fasting produced only slight modifications in the purin metabolism, the quantity eliminated diminishing without any apparent relation to the total nitrogen.

The problem of intermediary purin metabolism.—I, The storage of purin in the liver and its relation to the excretion of uric acid, H. ROSENBERG (*Ztschr. Expt. Path. u. Ther.*, 14 (1913), No. 2, pp. 245-254, fig. 1).—This article describes experiments made with the surviving livers of dogs and planned to show the effect of atophan on the storage and metabolism of purin bodies in the liver. Its effects in cases of gout, etc., under different dietary conditions are also touched upon.

The problem of intermediary purin metabolism.—II, Concerning uric acid puncture, E. MICHAËLIS (*Ztschr. Expt. Path. u. Ther.*, 14 (1913), No. 2, pp. 255-261, fig. 1).—These experiments were made with rabbits on which the operation known as the Claude Bernard sugar puncture had been performed. The operation increased the allantoin and also the total nitrogen content of the urine notably.

The conclusion is drawn that the center affected controls the purin metabolism as well as that of sugar, and indirectly influences the secretion of nitrogen. Hence, the operation might be correctly designated as uric acid puncture.

The effect of water ingestion on the fatty changes of the liver in fasting rabbits, M. R. SMIRNOW (*Amer. Jour. Physiol.*, 32 (1913), No. 6, pp. 309-314).—This paper, delivered before the Washington meeting of the American Association of Pathologists and Bacteriologists, May, 1913, describes experiments made with fasting rabbits to some of which no water was given. The author summarizes the changes in the livers as follows:

"Fasting, unwatered rabbits, from 4 days and upwards, show a decided fatty infiltration of the liver, apparent in gross and microscopically. Fasting, watered rabbits, from 10 days and upwards, may show similar changes in the liver, but the percentage of incidence is very low as compared with that of the unwatered animals.

"In half the number of fasting, watered rabbits under observation, microscopic vacuolation was observed. This vacuolation may be interpreted as a fatty change, but the picture is by no means comparable to that seen in the nonwatered animals."

The problem of fermentation and putrefaction in the human intestines during the administration of different types of diet as indicated by chemical analysis of the feces, H. FISCHER (*Ztschr. Expt. Path. u. Ther.*, 14 (1913), No. 2, pp. 179-244).—The studies on which this article is based were made with patients suffering from chronic constipation and receiving special diets, viz, a milk diet, vegetable and fruit diet, diet unusually rich in protein, diet unusually rich in fat, and the so-called Schmidt intestinal test diet (a simple mixed semi-invalid diet). The acidity or alkalinity of the feces was determined and also their content of volatile fatty acids, free and total ammonia, neutral fats, sulphuric acid, amino acids, mercaptan, etc., the hope being thus to throw light on the bacteriological conditions of the intestines as the result of the different diets.

Among the more significant points in the author's summary is the fact that the milk diet, the fruit and vegetable diet, and those rich in protein or in fat all yielded feces with noticeably high ammonia content. This indicates that the latter is not due simply to the decomposition of protein in the food, but may be caused, as in the case of the fruit and vegetable diet, by the prolonged retention of cellulose in the intestines and the increased putrefactive changes therein, or, as in the case of the fat diet, by the stimulation of the pancreas and other glands by the higher fatty acids and soaps and the irritation of the intestinal mucus by the lower fatty acids.

Calcium and phosphorus in growth at the end of childhood, HERBST (*Ztschr. Kinderheilk., Orig.*, 7 (1913), No. 3-4, pp. 161-192; *abs. in Zentbl. Expt. Med.*, 4 (1913), No. 10, p. 446).—Of the 2 subjects (14-year old boys) studied one was strong and the other less well developed.

Calcium and phosphorus metabolism were determined during long intervals. With the stronger subject there was a calcium oxid retention of 0.4543 gm. per day, equivalent to 165.8 gm. per year. With the less well developed boy the retention was 0.2172 gm. daily, or 79.3 gm. per year. These values are about the same as those calculated on theoretical assumptions.

Phosphoric acid retention in growth is apparently dependent upon calcium and also upon nitrogen retention.

Calorimetric observations on man, J. S. MACDONALD (*Rpt. Brit. Assoc. Adv. Sci.*, 1912, pp. 286-290).—These experiments were reported by the committee appointed by the British Association for the Advancement of Science to make calorimetric observations on man in health and in febrile conditions. They

were made with the calorimeter previously described (E. S. R., 27, p. 367). The usual temperature readings were made at 5-minute periods.

From these observations "the heat output of the subject (plus any heat arising from a subsequent conversion of mechanical work into heat) was calculated for each 5-minute period and the results platted as curves. By correction from observation these curves, altered by allowances for the storage of heat in the subject, were converted into heat-production curves—that is to say, curves representing the total transformation of energy within the calorimeter." These curves of heat output are "parallel to the surface temperature curves obtained simply by one set of observations during the first half-hour of each 'work experiment,' that is to say, so long as the observations of surface temperature are not complicated by the accumulated presence of surface moisture, and in some of the extremely light 'work experiments' continue in parallel fashion to the end of the experiment whilst showing corresponding variations at nodal points. . . .

"It would thus seem as if the transformation of energy per unit of mechanical work performed was a quantity that increased up to a certain value which was then maintained, and that the 'efficiency' of man as a machine varied in this fashion with the time spent in work. . . .

"If it is not the case, then two other lines of explanation have in addition to be examined. Thus it may be that the 'deep temperature' (rectal) is not a satisfactory criterion of the mean temperature of the human body and does not therefore provide a proper basis for corrections representing its average storage of heat during any short period (5 minutes) of time. It might, on the other hand, be the case that energy liberated during the performance of mechanical work as the outcome of oxidation processes developed as fully at the commencement as at the end of the experiment might be stored within the body, possibly within the musculature, in some form other than heat, as, for example, in the form of electrical energy, and therefore not discoverable by reference to changes of temperature."

In view of these considerations, the data obtained after the first hour were used in estimating the maintained efficiency of the subjects. The total transformation of energy in calories per subject per hour was calculated.

Previous calibration experiments with the cycle ergometer as driven by a special motor furnished the data for estimating the value in calories of the mechanical work performed by the subjects. Comparing the figures for the second and the fifth hours, an increment of work performance of 29.5 calories per hour was found in the subjects, the increment of increase in their total energy transformation for the same period being 119, 121, and 120 calories, respectively.

"It is clear, in the first place, that the 'efficiency' of these 3 different persons of different ages (45, 24, 36) and of quite different physical appearance and habits is almost the same, and in the second place that it is at least . . . of the magnitude of 24.6 per cent."

The energy produced by the processes of oxidation in the organism; physiology of muscular work, R. HÖBER (*Ztschr. Elektrochem.*, 19 (1913), No. 19, pp. 738-746).—This paper, delivered at the meeting of the Bunsen Society of Applied Physical Chemistry, Breslau, August, 1913, is a summary of the advance made in the knowledge of the chemo-dynamics of muscle from the time of Fick to the present.

According to the author, a muscle is to be regarded as a chemodynamical and not a thermodynamical machine, since it has so high an effectiveness that one would have to take into account extremely high temperatures if a thermodynamical explanation were offered.

The chief work reaction which causes contraction depends upon the formation of lactic acid. As yet the origin of the lactic acid is not known. Probably it does not come directly from glycogen or from dextrose. When muscle is stimulated and fatigued, the lactic acid disappears, oxygen being taken up and carbon dioxid given off, not, however, by means of simple combustion but through the regeneration of the lactic-acid-yielding substances coupled with an oxidative process. Muscular contraction is apparently brought about by a swelling which is itself brought about by the presence of the acid. The laws of the increased volume phenomena are the same as those for the dilution of concentrated solutions. In this case, as in the case of the muscle, practically all the energy changes can be noted as work.

A discussion follows the paper.

The influence of the temperature of the surrounding air upon carbon dioxid excretion in man—a contribution to the subject of heat regulation, L. SJÖSTRÖM (*Skand. Arch. Physiol.*, 30 (1913), No. 1-3, pp. 1-72, figs. 13).—Extended investigations are reported which led to the following conclusions:

Variations in the carbon dioxid excretion of a fasting man at rest, though not absolutely without muscular movement, are not influenced by surrounding temperature, so long as shivering is absent. Shivering causes an increase in the oxidation processes of the body for the purpose of maintaining constant body temperature, the increase being proportional to the intensity of such movement. The increased heat production caused by such means is not sufficient to maintain constant temperature in the body when heat is withdrawn in large quantities. Shivering is probably brought about, too, by nervous reaction in which the temperature condition of the skin plays a part. Whether or not higher temperatures than the surrounding air, 30 to 31° C., caused changes in the intensity of metabolism could not be determined from the experimental data reported. The author is of the opinion that possibly individual peculiarities had an effect upon this.

The influence of body position upon respiration in man, G. LILJESTRAND and G. WOLLIN (*Skand. Arch. Physiol.*, 30 (1913), No. 1-3, pp. 199-228, figs. 3).—According to the conclusions drawn by the authors from their investigations, respiration is influenced in a typical way by the body position, even in a condition of muscular rest and fasting.

Both the frequency and the volume per minute are greatest when standing, less when sitting, and still less when lying down. The number of respirations per minute was lower when lying upon the stomach than when lying upon the back. The changes in ventilation are in large measure directly dependent upon the change in frequency of respiration. The changes in frequency and in ventilation when frequency was constant for different body positions were not caused by variations in carbon dioxid production.

ANIMAL PRODUCTION.

Problems of genetics, W. BATESON (*New Haven, Conn., and London, 1913*, pp. IX+258, pls. 3, figs. 11).—The chapters included in this volume are as follows: The problem of species and variety; meristic phenomena; segmentation; the classification of variation and the nature of substantive variation; the mutation theory; variation and locality; local differentiation; climatic varieties; the effects of changed conditions; the causes of genetic variation; and the sterility of hybrids.

Experimental studies of the inheritance of color in mice, C. C. LITTLE (*Carnegie Inst. Washington Pub.* 179, 1913, pp. 11-102, pls. 5).—The conclusions of

the author of this treatise, which is divided into 2 parts, are based on personal observations made on more than 10,500 mice, the experiments dating from November, 1907, to May, 1912.

Part 1 (pp. 11-46) is a consideration of the factors producing color in mice. These are classified as formative and distributive color factors. The 3 general pigment-producing regions in mice were found to be the eye, the skin, and the hair, the pigments produced being limited to yellow, brown, and black. Color is attributed to the formation of melanin pigment, the product of an oxidation process. It is explained that "the presence of certain distributive factors, or modifications of them, determines what color varieties of mice shall be formed. These distributive factors determine either the total amount of pigmentation or the relative amounts of yellow, brown, and black that are visible."

Relative to the inheritance of spotting the author states that "experimental evidence does not support a theory which postulates the common origin of white produced by spotting and that produced by albinism." It is further explained that "present knowledge of spotted forms is too scanty to decide whether spotting is due to a process of loss of the factor for uniformity of pigmentation, or to a hypostatic restrictive factor. It seems, however, that such spotting as one encounters in guinea pigs, hooded rats, and in many mice, is a unit character subject to enormous quantitative fluctuation, and that it may be considered due to a modification of the factor *Y* or *U* which is hypostatic to unmodified or 'self' forms."

The observation of Morgan that "in crosses between self and spotted forms, in mice, the spotting seemed modified or contaminated by the cross," was corroborated. In crosses with Japanese waltzing mice, "the spotted individuals of F_2 have been contaminated by the cross, having their dorsal pigmentation increased on the average more than 50 per cent over the average of the pure Japanese race." Relative to "whether the various characters are completely independent of each other or whether coupling or gametic association of any sort exists between some of them," it was observed that experiments show no sign of association in the gametes between the several factors or between the 4 conditions characteristic of their absence.

Part 2 of this treatise (pp. 47-102) treats in detail of the experimental data obtained.

Heredity of tricolor in guinea pigs, H. D. GOODALE and T. H. MORGAN (*Amer. Nat.*, 47 (1913), No. 558, pp. 321-348, figs. 145).—Investigations carried on by the authors since 1908 to determine how the different types of tricolor in guinea pigs behave when mated to each other are reported.

With regard to the question of the heredity of black and white somatic areas, it is concluded that such an area or spot is "a center from which color, if present, is more likely to spread, and, if we assume somatic segregation in an early stage of the embryo the extent of the spot will be a measure of the extent to which a given cell containing the color factor multiplies as compared with neighboring areas that have the white factor. In pigeons the dark wing-bar of some breeds may be white in other breeds, although pigment is present elsewhere. We can not assume, of course, a pigment producer to be absent from the germ. It seems more probable that there are special color producers, which if present in the germ, and therefore in all the body cells, give a definite reaction in that region where a white band is formed. In this case there is no localization factor inherent as such, i. e., there is no need to assume somatic segregation, but only germinal segregation of a particular special factor that is realized in a special part. The substitution of a white area for a colored one in guinea pigs might

be looked at in the same way; but the extent to which the spot develops is a more difficult, and perhaps, a different problem."

Reversion in guinea pigs and its explanation, W. E. CASTLE (*Carnegie Inst. Washington Pub.* 179, 1913, pp. 1-10).—The author summarizes the results of his investigation as follows:

"The agouti coat characteristic of wild cavies and of most other wild rodents is dependent upon the presence in the fur of black pigment disposed in a definite pattern with red (or yellow). The factors which control, respectively, the development of black pigment and the production of the agouti pattern are independent of each other. The agouti coat is obtained only when both these factors are possessed by an individual. Only such agouti individuals as are homozygous in both factors breed true under all circumstances."

"An agouti animal which is homozygous in A (the agouti factor), but heterozygous in B (black pigmentation), may produce agouti young and red ones, but not black. An agouti animal which is homozygous in B, but heterozygous in A, may produce agouti young and black ones, but not red. An agouti animal heterozygous in both A and B may produce 3 sorts of young, agouti, red, and black. All F₁ (reversionary) agoutis produced by crossing black with red are of this sort. Agoutis of the other 3 sorts are obtained only in the second or later generations of agouti young."

Reciprocal crosses between Reeves pheasant and the common ring-neck pheasant producing unlike hybrids, J. C. PHILLIPS (*Amer. Nat.*, 47 (1913), No. 563, pp. 701-704, fig. 1).—It is shown that, unlike the case of many birds (fowls, pigeons, canaries, and doves) which give evidence of sex-linked characters, the pheasant hybrid shows "merely a different appearance of male sexual plumage character in the F₁ hybrids of a reciprocal cross between Reeves pheasant and the common ring-neck pheasant." This phenomenon evidently does not occur in the reciprocal crosses of other species of pheasants. No explanation is offered for the present case.

Some points of genetic interest in regeneration of the testis after experimental orchectomy in birds, C. J. BOND (*Jour. Genetics*, 3 (1913), No. 2, pp. 131-139, pls. 2, figs. 5).—In investigations of the results of unilateral oophorectomy in rabbits, the writer observed that "the removal of one ovary in the female rabbit is followed by a compensatory overgrowth in the remaining ovary, and further that this hypertrophy affects both the Graafian follicles or ova-bearing cells and the internal secretion-forming cells." It was found that in birds "the same process occurs in the remaining testis after unilateral orchectomy."

It was further observed "in both male fowls and pigeons that when one or both testes were removed intracapsularly—that is to say, when the testicular substance had been apparently wholly removed and the capsule alone left, a regeneration of the secreting tissue of the testis and the tubuli seminiferi took place within the capsule so evacuated. . . . This regeneration must take place either from the capsule, or more probably from microscopic fragments of secreting tissue which are left adhering to the capsule at the time of the operation." The testis of the domestic fowl apparently has greater powers of structural and functional regeneration after partial removal than exists in mammals.

With regard to "whether the gametes which are formed in this tissue resemble, in their hereditary characters, the gametes which are formed by the original gland before removal," the author's investigation seems to indicate "that the cell divisions of the motor sperm cells which provide the new spermatozoa formed during regeneration of the testis do not take place in exactly

the same order, or are not exactly of the same kind as those which form the sperm cells before removal of the sex gland."

It is suggested that further experiments should be made to confirm these conclusions and to determine other relations existing in the reproductive system of the fowl.

The segregation of fecundity factors in *Drosophila*, E. N. WENTWORTH (*Jour. Genetics*, 3 (1913), No. 2, pp. 113-120).—With a view to studying the effects of inbreeding upon fecundity and general vigor, the author conducted breeding experiments with flies. Four lines of breeding were started. "The largest and most vigorous males were mated with the largest and most vigorous females, the rather weak and small flies were mated together, and 2 lines of medium type, 1 based on size and the other on apparent vigor were also established."

After 9 generations, the breeding record of line 1 (a line lacking in vigor and high fecundity) presented a mean of 29.5 and a standard of variation of 7.31; line 2 (strongly vigorous), mean 135.86 and standard deviation 18.3; and line 3 (medium in size) and line 4 (medium in vigor), mean 72.06 and standard deviation 37.1618. From this the author concludes that "a segregation of fecundity factors is clearly evidenced and the supposed weaknesses from inbreeding are shown up in their true light as the mere segregation of factors for lower vigor."

It was further observed that "the male, whether he come from high or low lines, apparently in nowise influences the eggs laid by the female with whom he pairs, though marked differences, apparently due to segregation, may occur among his female descendants." The reciprocal crossing of strains high and low in fecundity, instead of resulting in 3 single groups, which might have been expected from previous calculations, showed at least 7. No evidence of sex linkage of fecundity factors appeared.

Determination of sex, E. TANSKY (*Hoard's Dairyman*, 46 (1913), No. 15, pp. 420, 421).—After an investigation of the 3-year records of over 600 head of cattle, to determine the percentage of males and females born by months, the author concludes that the month of birth favors no special sex.

Chemical composition of Roumanian and Russian sunflower seed cake, M. GÓRSKI (*Ztschr. Landw. Versuchsw. Österr.*, 16 (1913), No. 3, pp. 141-145).—Comparative analyses were made at the experiment station at Dublany, near Lemberg, of 2 varieties of sunflower seed cake, as follows: Roumanian cake, protein 27, fat 12.51, nitrogen-free extract 21.14, crude fiber 24.39, and ash 5.64 per cent; Russian cake, protein 33.01, fat 11.33, nitrogen-free extract 22.59, crude fiber 18.21, and ash 6.21 per cent.

On Perilla cake and Mowrah meal, F. HONCAMP, M. REICH, and H. ZIMMERMAN (*Landw. Vers. Stat.*, 78 (1912), No. 5-6, pp. 321-347, pls. 4).—Analyses of Perilla cake are reported as water 12.3, protein 36.31, fat 7.05, nitrogen-free extract 19.74, crude fiber 16.28, and ash 8.32 per cent. In sheep-feeding experiments for a period of 10 days, in which meadow hay and Perilla cake were fed and complete digestibility tests made, it was estimated that the digestible nutrients in Perilla cake were protein 36.02, fat 7.05, nitrogen-free extract 10.96, and crude fiber 1.3 per cent.

Analyses were also made of 3 grades of Mowrah meal, one of them showing the following composition: Water 14, protein 17.12, fat 2.17, nitrogen-free extract 53.55, crude fiber 5.62, and ash 7.54 per cent. Mowrah meal is used as a filler in feeds for domestic animals, especially molasses feeds and similar products. The presence of saponin in Mowrah meal and its resulting toxic effect upon animals being fed the meal is noted.

[Results of the examination of stock feeds], W. D. SAUNDERS (*Ann. Rpt. Dairy and Food Comr. Va.*, 4 (1911-12), pp. 67-99).—Results are given of the examination of stock feeds, misbranded, adulterated, or otherwise illegal.

Feeding stuffs (*Ber. Grossh. Bad. Landw. Vers. Anst. Augustenb.*, 1912, pp. 18-35).—Analyses are given of the pressed cake and meal of the following materials: Peanut, coconut, linseed, corn, poppy seed, palm nut, rape seed, sesame, soy bean, and sunflower seed.

Fresh meat supply of western Norway, R. M. RASMUSEN (*Daily Cons. and Trade Rpts. [U. S.]*, 16 (1913), No. 273, p. 958).—It is reported that the market for fresh meat is growing rapidly, owing to the industrial expansion, and that due to the high prices prevalent for the past few years stock raising is being revived. The natural conditions about Bergen are deemed unexcelled for stock raising, especially sheep.

Annual meeting of the Cattle Raisers' Association of Texas (*Cattle Raisers Assoc. Tex. Proc.*, 37 (1913), pp. 169).—A compilation of addresses and discussions relating to the cattle industry of Texas, and including the by-laws, rules and regulations, and list of members of the Cattle Raisers' Association of Texas.

A comparison of the observed and computed heat production of cattle, H. P. ARMSBY (*Jour. Amer. Chem. Soc.*, 35 (1913), No. 11, pp. 1794-1800).—Calorimetric investigations were made upon herbivorous animals, and in particular upon ruminants, to determine the difference between the actual and computed heat production. Previous experiments with carnivora and man had shown a close agreement, but it was thought that the physiological differences in the digestive operations of the ruminant might introduce factors tending to alter these calculations. Observations made during 8 years, 1902 to 1909, inclusive, embracing 57 experiments covering 48 hours each, are reported.

The results of these investigations show an average difference in the observed and computed heat production of cattle of +0.4 per cent, which corresponds very closely to results of previous investigations. It is concluded that "the same equivalencies between chemical energy, heat energy, and mechanical energy obtain in the bodies of herbivorous animals as in those of carnivora or of man, and, as a rule, elsewhere in nature."

Studies of the endogenous metabolism of the pig as modified by various factors, E. V. MCCOLLUM and D. R. HOAGLAND (*Jour. Biol. Chem.*, 16 (1913), No. 2, pp. 299-325).—This article is discussed under 3 headings, as follows:

I. *The effects of acid and basic salts, and of free mineral acids on the endogenous metabolism* (pp. 299-315).—In these experiments young pigs were brought to their lowest level of nitrogen elimination through several weeks of starch feeding. Daily analyses were made of samples of urine for the total creatinin, creatin, ammonia, and urea nitrogen. The author's conclusions are summarized as follows: "The endogenous metabolism of the pig reaches its lowest level when the animal has an abundant supply of carbohydrates together with a salt mixture of an alkaline character. The total output of nitrogen derived from endogenous sources can be greatly increased without changing the output of creatinin. The additional nitrogen which is eliminated on an acid over what appears on an alkaline diet is in the form of ammonia. The animal is not able to use the nitrogen of the urea fraction to neutralize the acids present in the diet, but draws additional nitrogen from the tissues for ammonia production."

II. *The influence of fat feeding on endogenous nitrogen metabolism* (pp. 317-320).—"Feeding fat as the sole source of energy does not lead to a sustained rise in the nitrogen output of pigs which have been reduced to their

lowest possible level of nitrogen metabolism by long continued starch feeding. Fat feeding may produce a considerable elimination of creatin. The total creatinin (creatinin+creatin) may be greatly increased without a corresponding rise in the total nitrogen output. The possibility of the acid or basic character of the ration having an influence on the creatin production is suggested."

III. *The influence of benzoic acid on the endogenous nitrogen metabolism* (pp. 321-325).—"A considerable amount of the nitrogen which appears in the form of urea in pigs reduced to the endogenous level of protein metabolism may be converted into glycocholi when benzoic acid is fed for the purpose of hippuric acid synthesis. When the quantity of benzoic acid ingested is not excessive, there is no noticeable rise in the total nitrogen excreted over that which is eliminated on the same diet without benzoic acid.

"When the quantity of benzoic acid ingested is very large, there is a marked increase in the output of total nitrogen catabolized. The urea nitrogen can not be reduced to a lower level than about 20 per cent of the total. No change in the creatinin output is observed when the protein catabolism is stimulated by excessive doses of benzoic acid. Endogenous protein metabolism appears to consist of at least 2 types. One can be stimulated greatly for ammonia production by the introduction of mineral acids, or for hippuric acid when benzoic acid is introduced; the other, measured by creatinin, remains unaffected by the methods we have described."

Value of potatoes as the basal feed for swine, F. LEHMANN (*Jour. Landw.*, 61 (1913), No. 3, pp. 361-397, pls. 2).—Four lots of 12 weeks' old pigs weighing approximately 20 kg. each were fed during a period of 22 weeks a basal ration of gram feed, fish meal, and chalk. In addition, lot 1 received during the period approximately 171 kg. of corn; lot 2, 671 kg. potatoes; lot 3, 717 kg. potatoes and 4.78 kg. rye chaff fed during the first 8 weeks of the experiment; and lot 4, 63 kg. potatoes, 36.5 kg. rye chaff, and 8.8 kg. meat meal, the meat meal being fed during the last 14 weeks of feeding.

The average daily gain per pig of lot 1 was 0.552 kg. (1.2 lbs.), with a total net profit at the close of the experiment of 10.68 marks (\$2.54); lot 2, 0.496 kg., net profit 6.91 marks; lot 3, 0.553 kg., net profit 14.11 marks; and lot 4, 0.553 kg., net profit 14.84 marks. From this it is concluded that a basal ration of potatoes supplemented with prepared feeds and balanced with a protein feed as meat meal is profitable.

The electro-cardiogram of the horse, J. NÖRR (*Ztschr. Biol.*, 61 (1913), No. 4-5, pp. 197-229, pl. 1, figs. 45).—This is a description of a specially prepared apparatus which when in contact with various parts of the body of the horse registers graphically the comparative duration and intensity of the heart's movements. There are included charts showing the heart action of the horse as determined by a number of trials.

On the variations in the growth of the exterior of the grade horse of East Prussia, W. VÖLTZ (*Landw. Jahrb.*, 44 (1913), No. 3, pp. 409-436, pl. 1, figs. 2).—Measurements and comparisons were made of the various bones of the limbs, head, breast, back, and general exterior of foals at one-half, 1½, and 2½ years of age, and the relative growth during these ages determined. Complete tabular data are given showing the measurements and percentages of growth at these ages.

Heredity studies in the royal stud at Trakehnen, B. SCHMIDT (*Arb. Deut. Gesell. Züchtungsk.*, 1913, No. 16, pp. X+363+XVI, pls. 22).—Parts 1 and 2 of this volume treat in detail of the improvement of some of the permanent Trakehnen stud strains by various methods of inbreeding. Part 3 deals with

the problem of the heredity of color, with a discussion of the Bunsow, Struwe, Crampe, and Walther theories on color inheritance and of the relation of these to the principles of Mendelian inheritance. Part 4 treats of hereditary diseases, including periodic ophthalmia, cribbing, roaring, and foal lameness.

The author's observations led to the conclusion that a pathologic fold of the eyelids is hereditary, especially in the maternal line. Periodic ophthalmia was found to be hereditary in some cases, and not in others. Roaring was proved to be hereditary. Spavin, navicular disease, and broken windedness were not transmitted; however, it is thought that the first 2 diseases can be transmitted by animals that are much affected by them.

Breeding and raising horses for the United States Army, M. F. DE BARNEVILLE (*Jour. U. S. Cavalry Assoc.*, 24 (1913), No. 99, pp. 411-415).—A general account of the horse-breeding and training operations in use at the Front Royal Remount Depot, Va., and at other remount depots.

How to buy a horse, C. W. GAY and D. S. MILLER (*Penn. Live Stock Sanit. Bd. Circ.* 24, pp. 9).—This circular briefly treats of the general principles to be observed in selecting and buying a horse.

The Shetland pony, C. and ANNE DOUGLAS (*Edinburgh and London, 1913*, pp. XI+176, pls. 25).—A very complete volume treating of the early history of the Shetland pony, present day types, and the care and management of this breed. There is appended a detailed account, by J. C. Ewart, of the physiological changes incident to the origin and development of ponies in general and this breed in particular.

The Grevy zebra as a domestic animal, G. M. ROMMEL (*Amer. Breeders Mag.*, 4 (1913), No. 3, pp. 129-139, figs. 5).—This is an account of the attempts to cross the Grevy zebra on the common mare. In one case there was a marked aversion on the part of the zebra, although no difficulty was experienced in mating with a jennet. In another case there was less antipathy on the part of the male zebra, but no mating resulted. Finally a number of mares were artificially bred, with one live foal resulting.

It was found that zebra semen does not contain relatively so many spermatozoa as does that of the stallion, and this is thought to account in part for the difficulty encountered in breeding by artificial means. It is noted that the ass hybrids have no value as work animals, being decidedly donkey-like in disposition and habits. The mare hybrid is more like a horse in appearance and manners.

The author calls attention to the fact that the Grevy zebra is characterized by its extreme quality or finish, which, if imparted in mule production would offset any coarseness in the mares. It is susceptible to domestication and it is thought that the size may be increased by feed and selection. With regard to the effect of so-called telegony, or the influence of prior impregnation, it was found that the mare which produced the zebra hybrid and afterwards was bred to a Morgan stallion, produced a foal showing no evidences of the zebra impregnation.

Contrary to the usual manner of ass-mare hybrids, the zebra-ass hybrids, both male and female, show sexual activity. They have been bred together, but without results. Evidently the relationship between the zebra and common ass is closer than that between the ass and horse. It is thought that the Grevy zebra would prove of value as a farm animal, if properly handled.

The call of the hen, or the science of the selection and breeding of poultry, W. HOGAN (*Petaluma, Cal.*, 1913, pp. 126, figs. 56).—The author outlines a method for ascertaining the value of a hen by the relative thickness of and distance apart of the pelvic bones. Tests for the determination of capacity, condition, stamina, prepotency, and laying ability are described.

The Campine history, B. A. GATES (*Franklinville, N. Y., 1913, pp. 46, figs. 19*).—This publication deals with the origin, distribution, development, feeding, care, management, and utility value of this breed of chickens.

[Second international egg-laying contest], J. O. HOWE (*Amer. Cult., 75 (1913), No. 46, p. 11, figs. 2*).—In this contest, held at the Connecticut Agricultural College, a White Leghorn broke the international record for egg production in a year by laying 282 eggs. The best pen of 5 laid 1,190 eggs.

Preservation of eggs by refrigeration in sterile air, M. F. LESCARDE (*Refrigerating World, 46 (1913), No. 5, p. 45*).—This is a description of an egg-preserving method whereby eggs are subjected to a mixture of carbon dioxide and nitrogen in an autoclave, and the cases of eggs taken out, hermetically sealed, and stored in cold storage rooms at a temperature varying between 33.8 and 35.6° F. By this method it is claimed that the waste of eggs is eliminated, the eggs retain a "fresh" flavor and their full weight, and remain in good condition longer after removal from cold storage. The cost of treatment and preservation, including all depreciation, is estimated to be 3.44 cts. per dozen.

German oyster culture, T. J. ALBERT (*Daily Cons. and Trade Rpts. [U. S.], 16 (1913), No. 178, p. 637*).—An account of a German oyster fishery comprising about 5,000 acres. It is stated that by careful cultivation it has been possible to produce oysters equal in flavor to any foreign variety. The methods of culture, feeding, and production for market purposes are explained.

DAIRY FARMING—DAIRYING.

Modern dairy guide to greater profits, M. H. MEYER (*Madison, Wis., 1913, pp. 88, figs. 10*).—A general treatise on modern dairy and creamery practice.

Dairying and butter making on small farms, M. A. O'CALLAGHAN (*Dept. Agr. N. S. Wales, Farmers' Bul. 65, pp. 13, figs. 3*).—This publication gives general instructions on the selection of dairy cattle, and on the feed, care, and management of dairy animals. The health of the herd is considered, together with methods of caring for milk and cream and farm butter making.

Correlation between form and function in the dairy cow, H. M. KROON and C. J. RAB (*Tijdschr. Veeartsenijk., 38 (1911), No. 21, pp. 789-822*).—Comparisons were made of the milk and milk-fat records of 100 Holstein cows in an effort to determine the correlation between these records and the body characteristics of the animals. The cows were grouped into 10 classes, according to milk yield (2,000 to 7,000 kg.) and milk-fat record (80 to 240 kg.), with a resulting classification giving the number of cows in each class as follows: As to milk yield, 5, 5, 16, 17, 22, 22, 8, 3, 1, 1; as to butter-fat yield, 9, 15, 17, 17, 23, 12, 5, 1, 1, 0. A close correlation between the milk yield and butter-fat record is thus noted.

Comparisons were then made of the body form and the number of animals of all classes for both milk and fat yield found under each body characteristic. In this case also the number of animals of each class for both milk and fat yield corresponded very closely. The body characteristics noted were length of head, breadth of forehead, shape of poll, thickness of horn at base, color and quality of horn, length of horn, quality of ear, hair growth on the head and poll, size of nose and mouth, color of nostril, and other similar points usually indicative of productive capacity.

There is appended a bibliography of 27 titles.

Red Polls for dairying, S. S. CAMERON (*Jour. Dept. Agr. Victoria, 11 (1913), No. 9, pp. 564-569, figs. 7*).—In this article the author reviews the successful work of the station herd of Red Poll cattle during 3 seasons. Milk-fat tests

ranged from 3.8 per cent to over 8 per cent, the average being approximately 4.5 per cent. The average milk-fat production per cow for each of the 3 seasons was, 255.77, 304.6, and 236.49 lbs., respectively.

It is stated that the crossing of these Red Poll cattle on native grade material produces the polled characteristics and an improvement in dairy qualities.

The new champion cow (*Milk Dealer*, 3 (1913), No. 1, p. 7).—An account of the Jersey cow, Eminent Bess, which now holds the world's record for performance for that breed, with a year's production of over 18,732 lbs. of milk and 963 lbs. milk fat. The record was made under the supervision of the Michigan Experiment Station.

Experiments with the milking machine, N. O. HOFMAN-BANG ET AL. (*Ber. K. Vet. og Landbohøjskoles Lab. Landøkonom. Forsøg* [Copenhagen], 81 (1913), pp. 43, figs. 5).—It was demonstrated that the use of the milking machine was entirely practicable, and except in the case of cows with sore or cracked teats, or poorly placed teats, the results obtained were practically equal to hand milking. The machine milking did not appear to have any influence on the fat content of the milk.

The report also describes trials with a milk cooler conducted during the year 1912-13.

Action of a pituitary solution as the active principle in milk secretion, B. A. HOUSSAY, L. GIUSTI, and C. MAAG (*Rev. Mens. Cdm. Merc.*, 13 (1913), No. 125, pp. 58-68).—This article outlines experiments in which a pituitary solution was injected into the blood stream of female animals with a view to determining the effect upon the milk secretion. The results corroborated those of Schäfer and Mackenzie (*E. S. R.*, 25, p. 680) and in general indicated a temporarily increased yield as the result of the injection of this solution.

Increase in the specific weight of freshly drawn milk, W. FLEISCHMANN and G. WIEGNER (*Jour. Landw.*, 61 (1913), No. 3, pp. 283-323).—Tests were conducted to determine the causes for the increase in the specific gravity or so-called "thickening" of milk, which takes place in the first few hours after milking and at temperatures under the melting point of milk fat. Investigations were made into the influence of the retention of absorbed gases on the specific gravity of milk, on the changes in the constitution of the milk sugars, on the consistency of the fat globules, and on the influence due to the so-called rise of casein. These explanations for the rise in specific gravity of freshly drawn milk were found to be unsatisfactory, and it was concluded that this phenomenon was due to the progressive coagulation of the milk fat, which is liquid at the time of milking.

Thickening did not occur when the milk was prevented from cooling at temperatures at which fat can coagulate, nor did it take place in separated milk in which the fat content was low. An increase in specific gravity was obtained under the requisite conditions with emulsions made from milk fat and water, while the phenomenon was not noticed with emulsions of oils which remain liquid at the temperatures in question. The increase in specific gravity of freshly drawn milk begins with the cooling under the melting point of the milk fats and lasts from 4 to 6 hours. Thereafter the specific gravity is constant at all temperatures.

The variation in the volatile fatty acids content of milk fat during the lactation period of 4 cows of the Royal Domain of Kleinhof-Tapiau, C. W. BEERBOHM (*Die Schwankungen im Gehalte des Butterfettes an flüchtigen Fettsäuren während der Laktation von 4 Kühen der Kgl. Domäne Kleinhof-Tapiau. Inaug. Diss., Univ. Königsberg, 1913, pp. 65, figs. 2*).—In these investigations it was found that the colostrum fat of the first milking had a very low content of water-soluble and insoluble volatile fatty acids. Both the period of lactation

and the feed had a distinct influence on the composition of the fats. There was an increase in the volatile water-insoluble fatty acids of the milk fat during almost the entire lactation period, and an increase in all of the volatile fatty acids during the spring and summer months when the cows were receiving pasture and green feed. The feeding of beets favored the formation of the volatile water-soluble and insoluble fatty acids.

Weather conditions had no appreciable influence on the character of the milk fat, but the individuality of the cow was found to be an important factor. The period of heat of the cow had the greatest effect on the diminution of the volatile soluble and insoluble fatty acids. A sudden change of feed effected an important change in the composition of the fats, noticeable only after several days of feeding.

With several of the cows there was an increase in the volatile water-soluble acids during the beginning of the lactation period, and a decrease with all the cows during the fall months. There was a larger amount of water-insoluble volatile fatty acids during winter feeding, and the smallest amount during the first few months of freshening. The insoluble volatile fatty acids in the fat in one case, however, was lower in the morning during the fall months and higher in the evening. Sickness of the cows produced a slight fall in the Reichert-Meissl and Polenske numbers. The highest value of the refraction exponent was in the fall months, and the lowest toward the end of the lactation period.

The maximum fall in the saponification number occurred during winter feeding, the minimum at the beginning of the lactation period. The highest Reichert-Meissl number was 32.44, the lowest 13.58; the highest Polenske number 4.89, the lowest 0.99; the highest Köttsdorfer number 242.4, the lowest 213.1. The highest refraction exponent was 48.2, the lowest 40.7. There was found to be a correlation between the refraction exponent and the other 3 factors.

On the milk fat of late milking cows, K. von FODOR (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 26 (1913), No. 5, pp. 235-237).—Comparing the milk fat of fresh cows and of those well along in lactation it was found at the experiment station for dairying at Magyar Ovar that the Reichert-Meissl numbers and saponification numbers were higher with the former than in the case of the latter, while the iodine test and refractive index were lower with the fat from the fresh cows.

First annual report of the International Association of Dairy and Milk Inspectors (*Ann. Rpt. Internat. Assoc. Dairy and Milk Insp.*, 1 (1912), pp. 131, fig. 1).—A compilation of papers and addresses delivered at this convention. It deals principally with the methods of inspection employed by the various city inspectors, but also includes papers on bovine tuberculosis eradication, economic milk production, and milk inspection from the standpoints of the producer and the milk dealer.

[Report on milk standards] (*Cream. and Milk Plant Mo.*, 2 (1913), No. 1, pp. 1-11, fig. 1).—This is the second report of the commission on milk standards and adopted by the American Public Health Association.

With respect to pasteurization it is recommended "that pasteurization of milk should be between the limits of 140° and 155° F. At 140° the minimum exposure should be 20 minutes. For every degree above 140° the time may be reduced by one minute. In no case should the exposure be for less than 5 minutes. . . . Pasteurization in bulk, when properly carried out, has proved satisfactory, but pasteurization in the final container is preferable." It is further urged that retail milk be labeled and marked, giving the grade of the milk and the date of production or of pasteurization.

The committee prescribes methods for bacteria count and the grading of milk accordingly. Definitions of the proposed grades of milk and cream are

given and provisions are made for the sale of homogenized and adjusted milks. It is advised that all milk be sold either under personal guaranty or under the regular state guaranty. Suggested standard rules for the production, handling, and distribution of both raw and pasteurized milk are appended.

Examination of Moscow market milk, A. WOJTKIEWICZ (*Centbl. Bakt. [etc.]*, 2. Abt., 39 (1913), No. 1-3, pp. 53-61).—A comparison is reported of the bacteria count, specific gravity, fat content, and general condition of the different grades of wholesale and retail milk in Moscow for the fall, winter, spring, and summer seasons, and of the relative percentage of sour milk bacilli, coli group, and gelatin-liquefying bacilli present during these seasons.

Methods of examination of clarifier milk slime, C. E. NORTH (*Abs. in Cream. and Milk Plant Mo.*, 2 (1913), No. 1, p. 19).—An examination was made of the slime resulting from the clarifying of milk.

Slime was invariably found in all milks, including certified. The amount of slime for individual cows ranged from 1.06 per cent to 1.14 per cent, and traces of slime were found in the milk even after the third and fourth clarification.

An analysis of this slime showed a total solids content of 30 per cent, of which 3 per cent was fat, 3 per cent ash, and the remaining 24 per cent nitrogenous organic compounds. Casein could not be found, and an occasional trace of blood was ascribed to the presence of pus. Purin, indicating the presence of cellular substances, was quite noticeable in fresh slime and decreased with the age of the slime. The presence of cellular elements, detected by microscopical examination, was ascribed to tissue cells and not pus cells. However, this point is under dispute. Occasional phagocytosis was noted. Mastitis milk frequently showed ten times the amount of slime that is found in normal milk.

Large numbers of bacteria were found in the clarifier slime, although there was no reduction in the bacterial count of the clarified milk. It is believed that in the process of clarifying, the clumps of bacteria are broken up by the force of the centrifuge, and that although a large number remain in the slime, the number of colonies is not materially lessened in the milk. In the belief that if the colonies were broken up by clarifying a subsequent pasteurization would be facilitated, experiments were made accordingly, but the results were disappointing.

In a discussion it is pointed out that leucocytes are always phagocytic, also that blood may be present in milk from herds not infected with any kind of disease. The presence of these bodies does not, therefore, necessarily denote the presence of pus cells.

Sampling for Babcock test, J. O. HALVERSON (*N. Y. Produce Rev. and Amer. Cream.*, 36 (1913), No. 21, p. 874).—Investigations were made to determine the factors which influence the percentage of milk fat obtained in ice cream samples. It was found that there was a great variance in these percentages, due to "(1) nonuniformity of the ice cream itself; (2) effect of testing charges taken at different times on ice cream samples which have stood, allowing the cream to rise to the top; and (3) method of mixing ice cream samples after having stood for some time."

On clean churning and related questions, L. F. ROSENGREN (*Meddel. Centralanst. Försöksv. Jordbruksområdet*, 1913, No. 77, pp. 24, figs. 4; *K. Landtbr. Akad. Handl. och Tidskr.*, 52 (1913), No. 4, pp. 254-275, figs. 4).—A study of the factors that influence the degree of the complete recovery of butter fat in churning cream in which the results of churning experiments with creams of similar fat contents at different churning temperatures, with cream of varying fat contents, and with churns filled with varying amounts of cream are pre-

sented. Trials with ice and artificial freezing mixtures in churning cream are also reported.

Brine salting cheese, J. H. MONRAD (*N. Y. Produce Rev. and Amer. Cream.*, 36 (1913), No. 18, pp. 754, 755).—The advantages claimed for this method are as follows:

"First of all it must be said that brine salting saves the cheese maker a good deal of work. The cheese lies in the brine 3 days and requires no work. The brine-salted cheese is firmer and hence easier and safer to take care of. Cheeses which lie in the brine are also salted quicker than by the old dry salting system, all of which saves considerable labor in making Emmental cheese. Another advantage is a saving in salt. If the preparation of the brine and the maintenance of its strength is done in a rational manner, nearly half the salt is needed. The brine-salted cheese keeps its shape better than by dry salting on the outside, is easier to keep clean, and preserves a fresher and more attractive appearance. The brine salting does not delay the ripening, indeed it rather hastens it."

In making the brine pure water is used, saturated with 20 per cent pure kitchen salt and at a temperature of 59° F. This method was first used in making skim milk cheese but has since been applied to the making of Limburger cheese.

Home cheese making without apparatus, A. CONLON (*Agr. Gaz. Tasmania*, 21 (1913), No. 6, pp. 208-212).—Directions are given for the making of home-made cheese.

Fresh cream cheese, A. ROLET (*Vie Agr. et Rurale*, 1913, No. 36, pp. 256-258, fig. 1).—A detailed explanation of the French method of making fresh cream cheese.

The manufacture of Grana cheese with a select ferment C. GORINI (*Agr. Mod. [Milan]*, 19 (1913), No. 13, pp. 147, 148, figs. 4).—Comparisons are made of the results obtained in the use of ordinary culture and a select ferment in the making of Grana cheese. It was demonstrated that with a select ferment the product is superior in consistency, taste, odor, and general condition.

On the abnormal ripening of Liptauer cheese, K. VON FODOR (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 26 (1913), No. 5, pp. 225-234, fig. 1).—In this article the author summarizes the results of tests made to determine the chemical and physical changes undergone in the ripening process of Liptauer cheese.

Reindeer milk and cheese, C. BARTHEL and A. M. BERGMAN (*Ztschr. Untersuch. Nahr. u. Genussmtl.*, 26 (1913), No. 5, pp. 238-241, figs. 2).—Four analyses were made of reindeer milk, the average composition being water 63.3, protein 10.3, fat 22.46, milk sugar 2.5, and ash 1.44 per cent. Reindeer cheese has a white color, a mild taste, and melts in the mouth. The rind has a sharp taste, but the inner portion has the characteristic delicate aroma of reindeer. The composition of the cheese is given as water 28.81, protein 22.57, fat 44.02, other organic matter 2.2, and ash 2.4 per cent.

The creamery industry: By-products and residues, A. ROLET (*L'Industrie Laitière: Sous-Produits et Résidus*. Paris, 1905, pp. VIII+395, figs. 162).—This volume treats very completely on all phases of creamery practice, dealing largely with the mechanical devices in common use, and treating of the manufacture of by-products such as fermented milk drinks and foods, condensed milk, and milk powder. The manufacture of a number of varieties of cheese is fully considered. Directions are given for determining the acidity and density of milk, and the extraction of milk sugar and the manufacture of alcohol and other products from waste milk are taken up in detail.

Experimental researches on the bacteriological and intoxicating character of the lactic acid food, "Gioddu," of Sardinia, G. ROSINI (*Mod. Zooiatro, Parte Sci.*, 1913, No. 3, pp. 87-100).—An account of the Italian lactic acid drink, "Gioddu," corresponding to yoghurt, koumiss, and kefir, and for which is claimed the property of antagonism to the pathogenic micro-organisms of the intestines.

VETERINARY MEDICINE.

Regional anatomy of domestic animals, L. MONTANÉ and E. BOURDELLE (*Anatomie Régionale des Animaux Domestiques. Paris*, 1913, pp. 1069; rev. in *Rec. Méd. Vét.*, 90 (1913), No. 5, pp. 195-199).—This is a new work intended for both the student of veterinary medicine and the practitioner.

Meat hygiene, T. E. MUNCE (*Penn. Live Stock Sanit. Bd. Circ.* 26, 1913, pp. 48, pls. 3, figs. 19).—This reports upon the abattoirs and meat inspection work in the larger municipalities of Great Britain, France, Germany, and Netherlands. A plan for either a private or municipal slaughterhouse is included.

Principles of milk hygiene for veterinarians, W. ERNST (*Grundriss der Milchhygiene für Tierärzte. Stuttgart*, 1913, pp. VIII+301, pls. 5, figs. 26).—This is the first edition of this work, which seems to have many features that are different from other works previously published on milk hygiene. Its contents are as follows: Anatomy, pathology, and the finer structure of the mammary gland; physiology of milk secretion and properties of milk in general; microscopy of milk; composition of milk and its biological, chemical, and physical properties; the production of cow's milk; internal and external causes affecting the composition of milk; bacteria in market milk and their origin and action upon milk; control of the milk supply; laws relating to the milk supply; and the examination of milk.

The book is illustrated with many plates and drawings.

Müller's serodiagnostic methods, P. T. MÜLLER, trans. by C. R. WHITMAN (*Philadelphia and London*, 1913, 3. ed., pp. XIII+146, figs. 7).—A clear, concise description of the methods used in serodiagnosis, with especial reference to human medicine, translated from the third German edition.

On the mechanism of complement fixation, H. R. DEAN (*Jour. Hyg. [Cambridge]*, 12 (1912), No. 3, pp. 259-289; abs. in *Ztschr. Immunitätsf. u. Expt. Ther.*, II, Ref., 6 (1913), No. 15, p. 1118).—The author finds that by making a series of dilutions with antisera, it is possible to determine the point where a definite amount of antigen will combine with the complement. In the absence of the latter it will give no precipitate, but if complement is added, a precipitate appears after several hours. By adding more complement a limited increase in the precipitate is noted.

Instead of using complement the same results can be obtained with the euglobulin prepared from guinea-pig serum. The precipitation of euglobulin is practically the same as that produced by carbon dioxide. The middle portion is fixed much quicker by the precipitation of an antigen-antiserum mixture than the end portion. The results show that the fixation of the constituents of complement is similar to the fixation which occurs with inorganic substances, e. g., barium sulphate suspensions, and that adsorption plays an apparent rôle in complement fixation.

Meiostagmin reaction and pregnancy, A. FULCHIERO (*Biochim. e Terapia Sper.*, 4 (1912), No. 3, pp. 58-61; abs. in *Ztschr. Immunitätsf. u. Expt. Ther.*, II, Ref., 6 (1913), No. 15, p. 1056).—In the experiments 35 sera from pregnant women and 35 control sera were examined with the meiostagmin reaction, 3 different kinds of methyl alcohol extracts being employed. All of the

sera from the pregnant women showed high values, but certain neoplastic sera gave increased figures also.

Glycosuria and allied conditions, P. J. CAMMIDGE (*London, 1913, pp. VII+467, figs. 2*).—This book, while dealing particularly with glycosuria, diabetes insipidus, etc., as they occur in man, is especially valuable for veterinarians interested in diseases of metabolism. It deals with the classification, properties, and physiology of the carbohydrates and their derivatives; the detection and differentiation of sugars and other reducing substances in the urine; the determination of the sugars, acetone bodies, nitrogen, etc., in the urine; experimental glycosuria; alimentary, transitory, and intermittent glycosuria; persistent glycosuria—urinary changes, blood and clinical symptoms, pathology and diagnosis, metabolism, treatment and prognosis; levulosuria, maltosuria, the occurrence of isomaltose, laiose, heptose, paidose, glycogen, animal gum, and inosit in the urine; lactosuria, galactosuria, saccharosuria, pentosuria, and the occurrence of glucuronic acid in the urine; alkaptonuria, diabetes insipidus; and the chemical properties and reactions of the carbohydrates and related substances.

Many bibliographical references are appended.

Experimental studies in glycosuria immunity, F. LANZARINI (*Riv. Clin. Pediatr.*, 10 (1912), No. 3, pp. 185-203; *abs. in Ztschr. Immunitätsf. u. Expt. Ther.*, II, Ref., 6 (1913), No. 15, p. 1057).—By treating a sheep subcutaneously with slowly increasing doses of glucose, it was possible later to give the animal a large amount of glucose without having it appear in the urine. A glucose-splitting ferment is elaborated in the system but the immunity produced is not permanent. The same findings were noted in a goat receiving saccharose but some of the enzymes produced in the blood were noted in the milk.

On the distribution of potassium in renal cells, C. P. BROWN (*Trans. Canad. Inst.*, 9 (1912), III, No. 22, pp. 389-407, pls. 2).—"The sodium cobalt hexanitrite reagent ($\text{CoNa}_3(\text{NO}_2)_6 + n\text{H}_2\text{O}$), as prepared by Professor Macallum, is a suitable reagent for the localization of potassium in kidney tissue. It is essential that the tissue be frozen while perfectly fresh, and that the sections prepared from it be kept frozen until they come in contact with the reagent. There is a definite localization of potassium on the external surface of the convoluted tubules and frequently about their lumina as well. The uniformity of this localization about the tubules tends to increase in direct proportion to the state of activity of the kidney. In the resting condition or during ordinary activity the only potassium demonstrable in the cytoplasm of the cells of the convoluted tubules is condensed in a layer immediately adjacent to the lumen border in each cell. This localization appears to be in accordance with surface tension phenomena.

"The presence of potassium in the lumina of the tubules and absence of potassium in the glomerular cavity is evidence that the inorganic salts are excreted by the tubule cells. No evidence bearing on the manner in which the glomeruli perform their function was obtained. In no instance was any potassium found in a cell nucleus. The amount of potassium in the kidney of the dog and even of the frog exceeds that of the sodium, and in the dog it exceeds greatly the amount of potassium in the blood or plasma."

The toxicity of gentian violet and its fate in the animal body, J. W. CHURCHMAN and L. F. HERZ (*Jour. Expt. Med.*, 18 (1913), No. 5, pp. 579-583, pls. 2).—Observations of the bactericidal properties possessed by gentian violet, and particularly of its affinity for pyogenic organisms, led the authors to attempt to determine the toxicity of this substance and its fate in the animal body. They here report upon a series of some 75 experiments made on dogs and rabbits.

Rabbits which received enormous doses (10 cc. of 1:200 solution) remained alive and were still perfectly well a number of months after the experiment. In another group of experiments, however, the animals died within a minute or so after injection. These experiments showed conclusively that blood withdrawn from animals thus injected possesses the selective bactericidal power of the dye, but that this power disappears completely in about 2 hours. There is no similar loss of selective bactericidal power when the dye is simply allowed to remain in contact with blood in vitro. Intravenous injection of gentian violet was found to result in prompt and fairly deep staining of the visible mucous membranes, and also appears in the mucous membranes lining the gastro-intestinal tract. The visible membranes remained stained about 48 hours, the stain disappearing slowly during this time.

The fate of the dye in other organs has not been determined. Frozen sections of tongues of dogs and rabbits painted with strong solutions of the dye showed that penetration had occurred through the thickness of the mucosa down to the muscularis.

Experiments on the cultivation of so-called trachoma bodies, H. NOGUCHI and M. COHEN (*Jour. Expt. Med.*, 18 (1913), No. 5, pp. 572-578, pl. 1).—"An organism was isolated and studied in pure cultures from cases of conjunctivitis accompanied by the so-called trachoma body inclusions, as well as from a case of old trachoma without inclusions. This organism was not found in the cultures made from other forms of conjunctivitis in which the inclusions were absent. The organism presents the morphological features characteristic of so-called trachoma bodies. It undergoes an early transformation, during which the forms known as initial bodies appear, and a later change, during which forms resembling elementary granules arise, while certain intermediate forms between these occur simultaneously. No definite cell inclusions could be produced in monkeys by inoculating pure cultures of the organism. The cultivation of this organism from a case of trachoma without the cell inclusions, together with the previously ascertained fact that the inclusions can be produced in suitable animals by inoculating such material directly from a human case, suggests the possibility of the organism being still present in such cases of trachoma, although not in the form of cell inclusions.

"The facts presented justify the statement that by a suitable method an organism resembling the various important stages of the trachoma bodies and totally distinct from the gonococcus has been obtained in a living condition capable of indefinite cultivation from cases of human trachoma and inclusion conjunctivitis. Whether the organism and trachoma bodies are identical can not be positively stated at present. But the way is now opened to determine this point, as well as the specificity of the trachoma bodies."

On the toxins of ascarids, H. DOBERNECKER (*Über Toxine der Askariden. Inaug. Diss., Univ. Bern, 1912, pp. 37*).—In this paper the author first reviews the literature at length (pp. 3-15) and then reports his own investigations. He concludes that the ascarids contain toxins in their body fluid which in man act particularly on the brain and in animals on the spinal cord, as well as irritating the skin and mucous membranes; that male and female ascarids of the same genus are equally toxic; that the body fluid of *Ascaris megalocephala* is more toxic than that of *A. lumbricoides*; and that the toxic action of the body fluid of ascarids is destroyed by the gastric juice.

Verminous toxins: A review, WEINBERG (*Bul. Inst. Pasteur, 10 (1912), Nos. 22, pp. 969-977; 23, pp. 1017-1026; 24, pp. 1065-1072*).—This paper, presented at the First International Congress of Comparative Pathology, held at Paris in October, 1912, deals with the subject under the headings of (1) indirect evidence, including verminous eosinophilia, and the passage of verminous toxins

into the host; and (2) direct evidence, including hemotoxins, toxicity of the liquids of parasitic cysts, ascarid toxins, teniotoxins, and the bactericidal properties of helminths. A bibliography of 2 pages is appended.

Investigations of a nematode and its faculty of producing papillomatous and carcinomatous neoformations in the stomach of the rat, J. FIBIGER (*Overs. K. Danske Vidensk. Selsk. Forhandl.*, 1913, No. 1, pp. 47-87).—A hitherto unknown disease of the stomach and of the esophagus of the rat (*Mus decumanus*), endemic in a single limited locality, was found to be caused by an undescribed nematode of the genus *Spiroptera*. The adult nematode infests the epithelium of the stomach and esophagus.

The cockroaches *Periplaneta americana* and *P. orientalis* serve as intermediate hosts. The eggs of the nematode which pass out in the excrement of the rat are ingested by the cockroaches, develop, and the embryos become localized in the striated muscles of the prothorax and the legs. The rats become infested by eating cockroaches, and the embryos of the worm, set free from their cysts, attack the epithelium of the stomach, sometimes also that of the esophagus, tongue, and buccal cavity, and develop into the adult nematode. The author's investigations lead him to conclude that all the anatomical alterations are due to toxic products of the nematode.

From the primary lesions caused by the nematode secondary metastases may be produced in other organs; the metastases contain neither the parasites nor their eggs. The development of the metastases is due to the faculty of the epithelial cells of multiplying in other organs independently of the parasite. The author thus confirms the view put forward by Borrel and Haaland that nematodes may produce malignant tumors in rats and mice.

A contribution to the study of nematode parasites of the dog's eye, A. RAILLIET and A. HENRY (*Bul. Soc. Cent. Méd. Vét.*, 90 (1913), No. 10, pp. 209-215, figs. 6).—Following a review of the reports of 3 observations by others of nematode parasites in the dog's eye, 2 relating to intra-ocular parasites and 1 to an extra-ocular parasite, the authors report on the occurrence of a fourth, a female *Hæmostrongylus vasorum*, in the anterior chamber of the eye of a dog at Laval, France.

Combating contagious abortion, HASENKAMP (*Arch. Wiss. u. Prakt. Tierheilk.*, 39 (1913), No. 4-5, pp. 422-434, fig. 1).—A description of epizootics of contagious vaginal catarrh and contagious abortion which occurred in all of the districts of the Province of Westphalia.

The light acute cases of vaginal catarrh were treated successfully with Bengen's vaginal capsules, but the severe acute cases did not respond to this treatment despite the fact that it was continued for weeks and the stables were thoroughly disinfected. Bissulin also did no good. In 3 barns unsatisfactory results were obtained with Gans' lymph.

As the tampon method seemed to present some favorable features, it was tried, and for preventing the tampon from being expelled, a special form of apparatus was constructed which the author calls the tampon holder or retainer. The tampons before insertion were impregnated with a 3 per cent lysoform or sapoform solution, and were kept in the vaginal cavity for 24 hours. In severe cases a new tampon was inserted for 12 hours longer. In about 5 days the lesions in the mucous membrane of the vaginal canal had been removed. The method was used in 1,000 cases and was applied by 8 veterinarians. It is deemed advisable after the disease has been removed to wash out the vaginal cavity with a 2 per cent solution of sodium bicarbonate, especially before the animal is served.

For combating contagious abortion in cows Schreiber's method (E. S. R., 28, p. 380) was used in 2 establishments, but found to be unsatisfactory,

although the animals received in addition a subcutaneous injection of 10 cc. of a 2 per cent carbolic-acid solution each week. Also the animals in 6 small herds were divided into 2 groups, one-half receiving Schreiber's lymph and the other half being treated by Bräuer's carbolic-acid method.^a Bräuer's method gave the better results, and Schreiber's lymph is not a certain method for preventing abortion. See also the work of Taylor (E. S. R., 28, p. 781).

Peptotoxin production by the bacillus of contagious abortion of cattle, J. REICHEL and M. J. HARKINS (*Centbl. Bakt. [etc.]*, 1. Abt., Orig., 69 (1913), No. 3, pp. 142-163).—The *Bacillus abortus* was found to produce a toxin when cultivated on a medium containing peptone, but would not develop it on a non-peptonized medium. It was possible to remove the toxin from the bacilli by thoroughly washing with water. By adding alcohol to the supernatant fluid obtained from a suspension of bacilli grown on peptonized agar, a precipitate was obtained which contained the toxic substances. Heating the toxin for 30 minutes at 65° C. had apparently no effect on its toxic properties. It was found, however, that in order to make cattle react toward the toxin they must first be sensitized to it.

"*B. typhosus*, *B. coli communis*, *B. tetani*, and pneumococcus cultures on peptonized agar revealed the presence of peptotoxin when injected into animals sensitized to the abortus bacillus or its products. The peptotoxins of these organisms probably have much in common, if they are not one and the same substance, because animals can be sensitized with one for any of the others. No reactions were observed following the injections into sensitized animals of peptonized agar cultures of the diphtheria bacillus, *Staphylococcus pyogenes aureus*, nonhemolytic streptococcus, and hemolytic streptococcus, which may mean that the organisms did not produce peptotoxin or only in very small amounts.

"Rabbits developed agglutinins following the injection of thoroughly washed and unwashed abortus bacilli equally well. The peptotoxin injected with the unwashed bacilli is not essential in the production of antibodies. In that the abortus bacillus produces peptotoxin in a protein medium and it is a possibility that peptotoxin is produced in milk with the bacilli from cattle in infected herds, the wholesomeness of such milk is more questionable."

Certain individual differences were noted in the amounts of peptotoxin produced by various strains of the *B. abortus*, as noted by McFadyean et al. (E. S. R., 22, p. 584).

Hyperimmunization of horses for obtaining an antianthrax serum, I. G. EIGEN (*Arch. Vet. Nauk. [St. Petersburg.]*, 42 (1912), No. 7, pp. 637-646; *abs. in Centbl. Bakt. [etc.]*, 1. Abt., Ref., 56 (1913), No. 12, p. 357).—The serum can be obtained in as short a time as 3 months providing the horses are treated daily with small doses of virulent anthrax bacilli.

Testing of Grugel's vaccine against foot-and-mouth disease, NEVERMANN (*Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 30, pp. 537, 538).—In the experiments 13 cattle were used. Ten of these were treated with the vaccine and 3 were kept as controls. In no case did the vaccine prove of any value for protecting animals against foot-and-mouth disease.

Technique and practical significance of precipitation for the intravital and post-mortem diagnosis of glanders, J. LENFELD (*Ztschr. Infektionskrankh. u. Hyg. Haustiere*, 14 (1913), No. 1, pp. 68-90).—Precipitation is deemed an important aid for diagnosing the intravital presence of glanders. A systematic examination of blood resulted in establishing the presence of the disease in 100 per cent of the cases, while 1 examination of blood showed it to be present in

62 per cent, and when the test was made in combination with the ophthalmic reaction, 78 per cent of the cases were detected.

For the post-mortem detection of the disease the test will probably prove positive each time that the organs are utilized for making the extracts.

About the preparation of bacillary extracts for complement fixation, W. PFEILER and G. WEBER (*Ztschr. Immunitätsf. u. Expt. Ther.*, I, Orig., 15 (1912), No. 2-3, pp. 180-185; abs. in *Centbl. Bakt. [etc.]*, 1. Abt., Ref., 56 (1913), No. 12, p. 359).—It was found that repeated shaking of the glanders bacillus suspensions in preparing extracts was unnecessary. It is sufficient simply to centrifuge the suspension and to utilize the uppermost clear fluid for the tests. Bacillary suspensions could be boiled without affecting their activity. An analogous finding was noted with the hog cholera bacillus and other micro-organisms.

Malta fever: Cases occurring in Arizona, C. E. YOUNT and R. N. LOONEY (*Ariz. Med. Jour.*, 1 (1913), No. 4, pp. 18-27; abs. in *Jour. Amer. Med. Assoc.*, 60 (1913), No. 22, p. 1740).—A description of 5 cases of malta fever in man, as previously noted (*E. S. R.*, 27, p. 884).

Malta fever in Louisiana, C. WELLMAN, A. EUSTIS, and S. S. SCHOCHET (*Amer. Jour. Trop. Diseases and Prev. Med.*, 1 (1913), No. 5, pp. 393-396, fig. 1).—The authors report upon a case of Malta fever in a man, detected at New Orleans by means of the agglutination tests, who evidently became infected in Jackson County, Texas.

Immunizing tests against rabies, H. MIESSNER, KLIEM, and KAPFBERGER (*Arch. Wiss. u. Prakt. Tierheilk.*, 39 (1913), No. 3, pp. 169-209; abs. in *Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 21, p. 386).—The purpose of the work was to devise a method for immunizing domesticated animals against rabies. The various methods used for man are based on the principle that small doses of attenuated fixed virus are necessary to bring about immunity. In these experiments it was found that with 3 intravenous injections of fixed virus it was possible to produce an immunity, providing the control infection of the animal was allowed to follow some weeks later. The formation of immune bodies proceeds slowly. For the dog the intra-abdominal route is preferred. The curative treatment occupies a secondary position. It is advisable to immunize all animals (dogs) yearly.

The tests for preparing a highly potent immune serum for all classes of animals have not been completed. Tests with salvarsan against this disease were conducted but with negative results. The detection of Negri bodies in rabbits used for the transference (passage) experiments with fixed virus was successful in 80 per cent of the cases. The transference of virus from mother to fetus was also noted. Three animals (1 sheep and 2 rabbits) infected with street (passage) virus became rabid in 2 days. The aqueous and vitreous humor of rabid rabbits' eyes can produce typical rabies when injected into other rabbits.

New immunizing tests in rabies, W. PFEILER (*Berlin. Tierärztl. Wchnschr.*, 29 (1913), Nos. 14, pp. 249-252; 15, pp. 269-273).—After giving a description of the research work which led up to the discovery of the antirabic vaccination and the details of the various modifications of Pasteur's method, attention is called to the value of immunizing domesticated animals against rabies. The number of tests thus far conducted is regarded as inadequate to properly judge the efficiency and practical utility of immunization.

The results of tests conducted at the Emperor William Institute of Agriculture at Bromberg by Miessner, Kliem, and Kapfberger are discussed in the article. All animals, with the exception of those from which it was desired to obtain an immune serum, were immunized by the rapid method. Some of the tests seemed satisfactory while others were entirely discouraging.

The author has had under observation over 30 dogs which were completely immune and thoroughly refractory toward rabies. The animals received from 4 to 8 gm. of fixed virus intraperitoneally and these amounts were able to protect the animals against an infection with fixed or street virus which was given 14 days following the vaccination. Subcutaneous injections, when given as recommended by Ferran, always produced a strong inflammation of the subcutaneous tissue, consequently this method of injection was abandoned. A part of the animals were infected either subdurally several months later, or were bitten by a rabid animal, with the result that all of the animals remained sound. In another series of experiments manifestations of immunity were noted when immune serum was injected intravenously, subcutaneously, or intraperitoneally in animals, but when the serum was introduced into the spinal canal the animals (dogs and sheep) were absolutely protected. Probably a local immunity was concerned here. With this new intraspinal method 16 sheep, about 20 dogs, about 80 rabbits, and 1 horse were treated.

In regard to Miessner's report with reference to immunizing animals against rabies, W. PFEILER (*Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 30, pp. 540-543).—A polemic.

Immunizing dogs against rabies, W. PFEILER and G. KAPFBERGER (*Ztschr. Infektionskrankh. u. Hyg. Haustiere*, 13 (1913), No. 6, pp. 307-316).—This is a detailed statement of the results of an investigation, noted above, with experimental data.

In regard to immunizing against rabies, MIESSNER (*Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 31, p. 558).—A reply to the above.

Sporotrichosis of animals, DE BEURMANN and GOUGEROT (*Rev. Gén. Méd. Vét.*, 21 (1913), Nos. 250, pp. 557-586; 251, pp. 626-645, figs. 21).—This paper on the comparative pathology of sporotrichosis takes up the subject under the headings of spontaneous sporotrichosis of the rat, dog, mule, and horse; experimental sporotrichoses of animals; clinical diagnosis; and prognosis and treatment.

The trypanosomes causing dourine (*mal de coït* or *Beschälseuche*), B. BLACKLOCK and W. YORKE (*Proc. Roy. Soc. [London]*, Ser. B, 87 (1913), No. B 593, pp. 89-96, pl. 1, figs. 3).—This is in continuation of work of which a preliminary account has been previously noted (*E. S. R.*, 27, p. 884). The morphology of three strains of the trypanosome, supposedly *Trypanosoma equiperdum*, one originating in Algiers and the other two in Germany, was studied. The authors are led to conclude that the symptom-complex of the disease, clinically known as dourine, can be produced by more than one species of trypanosome. They were unable to distinguish morphologically the Algerian form from *T. rhodesiense*, *T. pecaui*, *T. brucei*, and *T. ugandæ*.

Studies of the piroplasmoses occurring in Algeria (*Bul. Soc. Path. Exot.*, 6 (1913), Nos. 8, pp. 571-574; 9, pp. 618-623).—The first paper (pp. 571, 572), by E. Sergent, A. Lhéritier, and R. Ismert, relates to equine piroplasmosis in Algeria and its cure by trypanblue; the second paper (pp. 573, 574), by E. Sergent and M. Beguet, reports upon the occurrence of *Anaplasma marginale* in cattle in Algeria. An acute and very grave case of piroplasmosis in a horse was observed in a region from which the disease had not previously been reported but where bovine piroplasmosis is enzootic. This case rapidly recovered following the injection of trypanblue. A number of preparations of blood from cattle presenting symptoms of piroplasmosis were found to contain *A. marginale*. The third paper (pp. 618-622), by E. Sergent, A. Lhéritier, and A. Boquet, relates to the treatment of bovine piroplasmosis by trypanblue; the fourth paper (pp. 622, 623), by E. Sergent and A. Lhéritier, reports upon an intense piroplasma infection in apparently healthy cattle.

Tubercle bacilli in the circulating blood in surgical tuberculosis, M. KRABBE (*Deut. Ztschr. Chirurg.*, 120 (1913), No. 3-4, pp. 370-378; *abs. in Jour. Amer. Med. Assoc.*, 60 (1913), No. 9, p. 705).—Eighteen patients having surgical tuberculosis were examined for the presence of tubercle bacilli in the blood, and in 12 of the cases the organisms were found. Five subjects having tuberculous lymph nodes showed positive in one case, and positive results were obtained in 1 out of 4 cases having tuberculosis of the mucosa, skin, or tendon sheaths.

Report on the results of a chemical investigation [of the tubercle bacillus], A. HARDEN (*Roy. Com. Tuberculosis, Final Rpt., pt. 2, 6* (1913), pp. 34).—This details the results of an investigation instituted at the request of the Royal Commission on Human and Animal Tuberculosis for the purpose of ascertaining whether it is possible by chemical means to differentiate between the human and bovine types of bacilli. The viruses employed were of bovine, porcine, and human origin.

Part 1 of the work deals with the changes produced by growing the bacilli in glycerol veal broth. The determinations made after filtering off the bacterial growth, which was weighed, were total nitrogen, nitrogen nonprecipitable by tannic acid, nitrogen nonprecipitable by phosphotungstic acid, free and saline ammonia, ammonia liberated by hydrolysis with hydrochloric acid, acidity of the medium to phenolphthalein in the cold and at the boiling point, acids soluble in ether, and the amount of glycerol present.

From this part of the investigation it was concluded that "no definite physiological difference has been detected between tubercle bacilli of different origins. Such differences as exist between the amounts of action exerted on glycerol beef broth by different cultures are probably to be attributed to differences between the weights of organisms formed, the times of incubation, and individual characteristics of the strains. When *Bacillus tuberculosis* is cultivated on glycerol broth, the proteins of the broth undergo hydrolysis to a considerable extent. Glycerol is partially removed by oxidation. There is no evidence that consumption of glycerol is directly related either to weight of culture obtained or to change in acidity. The initial fall in the acidity of the medium is largely due to the removal of the acids soluble in ether (lactic acid, etc.). Further important factors in producing change in acidity are the production and removal of ammonia (free and saline) and the digestion of the proteins."

Part 2 is devoted to a study of the relation of the ash and phosphoric acid present in tubercle bacilli of different origins. The conclusion is reached that it is impossible to characterize tubercle bacilli of different origins by the amount or composition of the ash, or the phosphoric acid which they contain. See also other notes (*E. S. R.*, 10, p. 1016; 13, p. 994; 14, p. 693).

Hypersensitiveness to tuberculo-protein and to tuberculin, C. R. AUSTRIAN (*Bul. Johns Hopkins Hosp.*, 24 (1913), No. 267, pp. 141-147; *abs. in Jour. Amer. Med. Assoc.*, 60 (1913), No. 21, p. 1665).—The experiments confirm other already demonstrated facts that "(1) a protein substance can be obtained by the extraction of tubercle bacilli with water, and with it animals can be actively sensitized; (2) that a refractory condition to this protein can be produced; and (3) that the hypersensitive condition is transmitted from mother to young. [The author's] experiments establish further that active sensitization induced by treatment with this protein may be as regular in its development and as intense in its manifestation as is that produced by treatment with other proteins. Passive homologous and heterologous hypersensitiveness can occasionally be produced with the blood or with the serum of an actively sensitized animal. The material transmission of the hypersensitiveness does not take place through the milk. The regularity with which maximum hypersensitive-

ness can be produced is largely dependent on the use of a sufficient amount of protein in preparing and in testing the animals. All the manifestations of typical hypersensitiveness to protein can be produced in guinea pigs by treatment with aqueous extracts of tubercle bacilli. Guinea pigs can be sensitized with albumose-free tuberculin and with old tuberculin that has been freed of glycerol and made poor in salts; and sensitization with any of these products causes the animal to react to injections of the others.

"Hypersensitiveness to tuberculin develops within 7 to 15 days after infection with the *Bacillus tuberculosis*. Tuberculous animals can occasionally be intoxicated with tuberculo-protein, developing symptoms of hypersensitiveness. The passive transference of hypersensitiveness from a tuberculous man to normal guinea pigs has been successfully accomplished and positive results have likewise been obtained when the serum of a sensitized animal has been injected into an untreated one. The type of the reaction symptoms and the development of them in an infected host after the administration of minimum doses of tuberculin are likewise suggestive facts."

The author is of the opinion that the evidence gathered justifies the interpretation of the tuberculin reaction as a manifestation of hypersensitiveness.

Tuberculin in diagnosis and treatment, L. HAMMAN and S. WOLMAN (*New York and London, 1912, pp. XIV+381, figs. 35*).—This publication contains a detailed description of the various tuberculin reactions utilized at the present time, and discusses the scientific principles underlying the diagnostic and therapeutic use of tuberculin. These topics are considered particularly from the human standpoint.

The relative value of turtle tuberculin in the treatment of tuberculosis, W. J. BEATTIE and E. E. MYERS (*N. Y. Med. Jour.*, 98 (1913), No. 11, pp. 503-507).—A discussion in regard to Piorkowski's antigen, the Friedmann cure, and von Ruck's vaccine. The use of Piorkowski's tuberculin for this disease in man is described in detail.

Treatment of tuberculosis with attenuated tubercle bacilli treated with sodium fluorid, G. RAPPIN (*Arch. Gén. Méd.*, 203 (1913), pp. 262-278; *abs. in Jour. Amer. Med. Assoc.*, 60 (1913), No. 19, p. 1497).—The vaccines used in treating laboratory animals were made from attenuated tubercle bacilli deprived of their protective envelope by sodium fluorid. The cultures used in the experiments have been cultivated since 1894, and this is the fourth report on the topic. The results obtained with guinea pigs were very satisfactory.

On a remarkable new type of protistan parasite, H. M. WOODCOCK and G. LAPAGE (*Quart. Jour. Micros. Sci. [London]*, n. ser., 59 (1913), No. 235, pp. 431-457, pls. 2, figs. 2).—This paper describes a new type of parasitic Protista which inhabits the rumen of animals, especially of the goat, to which the authors have given the name *Selenomastix ruminantium*.

"Apparently the only flagellates from which the organism could be derived are the dinoflagellates and, apart from the transverse division, there is no indication of any affinity with this group. Further, the nature of the nucleus and the capacity of moving by the body alone make it very doubtful if this parasite is a true protozoan. *S. ruminantium* differs in important respects from any known bacteria. It has no affinities with schizosaccharomycetes, with Blastocystis, nor with the spirochetes. In certain characters it shows a resemblance to one or two large spirillar forms, or to certain members of the sulphur bacteria (e. g. *Ophidomonas*), but while its derivation is possibly to be sought in this direction, it is, nevertheless, very far removed from such forms. We may have in *Selenomastix* an example of a proflagellate."

The relation of lungworms of sheep to those of deer, E. RICHTERS (*Ztschr. Infektionskrank. u. Hyg. Haustiere*, 13 (1913), No. 5, pp. 251-272, figs. 15; *abs.*

in *Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 7, pp. 1058, 1059).—Investigations were carried on to determine the species of *Strongylus* occurring in the lungs of sheep and deer and how the embryos and mature parasites differ from each other.

On an average, 95 per cent of those found in sheep are *Strongylus filaria* (*Dictyocaulus filaria*) and 5 per cent *S. commutatus* (*Synthetocaulus commutatus*). In many hundreds of lungs examined by the author no other species were found. The sexually mature worms occurred either in the tracheæ or in the bronchi, never in the lung tissue. The author finds *S. commutatus* to be a distinct species, but, contrary to hitherto accepted opinions, *S. capillaris* (*Synthetocaulus capillaris*) and *S. rufescens* (*Synthetocaulus rufescens*) found in sheep appear to be identical.

The lungworms found in deer are exclusively *S. micrurus* (*Dictyocaulus viviparus*), neither *S. micrurus*, *S. sagittatus* nor any other species being found in the 100 cases investigated. Thus it would appear that the lungworms of sheep are distinctly different from those of the deer and that transmission from sheep to deer is very unlikely.

A bibliography of 64 titles is appended.

Anaplasmosis of the sheep in German East Africa, O. TRAUTMANN (*Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 33, pp. 593, 594).—The author confirms the previous observations of Schellhase* of the occurrence of anaplasmosis (*Anaplasma marginale*) of sheep in German East Africa.

Cholera in northwest Iowa, O. W. JOHNSON (*Breeder's Gaz.*, 64 (1913), No. 22, pp. 1038, 1039).—It is pointed out that hog cholera may be disseminated by crows, since they feed on the carcasses of dead hogs and may then fly from 1 to 20 miles and light in hog pastures or in trees under which hogs seek shade.

The practical treatment of the horse, W. H. EDGAR (*Atlanta, Ga.*, 1913, pp. 96).—A popular account.

Cerebro-spinal meningitis of the horse, B. F. KAUFF (*Amer. Vet. Rev.*, 44 (1913), No. 1, pp. 75-87, fig. 1).—The author discusses the history of the outbreak of cerebro-spinal meningitis in the Middle West in 1912, particularly in Colorado, and its differential diagnosis; and reports several cases of the disease, including histological and bacteriological studies. He states that no definite conclusion as to the cause of the disease can at the present time be drawn.

Treatment of pectoral influenza (Brustseuche) with neosalvarsan, STÖDTER (*Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 11, pp. 195-198; *abs. in Rev. Gén. Méd. Vét.*, 21 (1913), No. 249, pp. 518-520).—Two horses treated by the author on the third day and a third on the fourth day of the disease, with intravenous injections of 4½ gm. of neosalvarsan in 130 gm. of lukewarm (22° C.) 0.4 per cent salt solution, made rapid recoveries. The only objection to the use of this preparation is its high price, each injection costing 42 marks (\$10.00), and it is estimated that the high percentage of recovery resulting, the shortening of the course of the disease, and the complete and definite cure make its use economical. It is stated that during 1911, 226 animals were treated with salvarsan with but a single loss, although the usual mortality from the disease runs from 5 to 20 per cent.

Concerning the beri-beri-preventing substances or vitamins contained in rice polishings—a sixth contribution to the etiology of beri-beri, E. B. VEDDER and R. R. WILLIAMS (*Philippine Jour. Sci., Sect. B*, 8 (1913), No. 3, pp. 175-195).—Investigations are reported in continuation of earlier work (E. S. R., 29, p. 180).

Some of the conclusions follow which were drawn from experiments reported.

* Berlin. Tierärztl. Wchnschr., 28 (1912), No. 28, pp. 511, 512.

"Undermilled rice may be stored for 1 year in a damp place without losing its protective powers against polyneuritis gallinarum. It is improbable therefore that a rice which originally affords protection against beri-beri will lose this property by storage even in damp places. . . .

"The therapeutic properties of an alcoholic extract of rice polishings are greatly altered by hydrolysis (treatment with 5 per cent hydrochloric or sulphuric acid). The unhydrolyzed extract is not poisonous and is only slowly curative. The hydrolyzed extract is exceedingly poisonous in large doses and promptly curative in small doses.

"We have confirmed Funk's observations by isolating a crystalline base from an extract of rice polishings by Funk's method. This base in doses of 30 mg. promptly cured fowls suffering from polyneuritis gallinarum. . . .

"Two groups of substances (purin bases, cholin-like bases) may be isolated from rice polishings in addition to Funk's base and are capable of partly or wholly protecting fowls fed on polished rice against polyneuritis gallinarum, but are incapable of curing fowls that have already developed the disease. The chemical nature of these two groups of bases requires further investigation. . . .

"It is probable that this base [Funk's base] or vitamin exists in food as a pyrimidin base combined as a constituent of nucleic acid, but that it is not present in the nucleins or nucleic acids that have been isolated by processes involving the use of alkalis or heat."

The authors regard their results as affording striking and confirmatory evidence for the hypothesis which has been previously advanced that wet beri-beri and dry beri-beri are two distinct conditions, each being caused by the deficiency of a separate vitamin.

Other conclusions have to do chiefly with the chemical characteristics of the vitamins and clinical experience.

The use of milk cultures of *B. bulgaricus* in the prevention and treatment of bacillary white diarrhea of young chicks, L. D. BUSHNELL and O. MAUREB (*Amer. Vet. Rev.*, 44 (1913), No. 2, pp. 194-207).—Following a general review of the subject the authors report feeding experiments with *Bacillus bulgaricus* and *B. pullorum*, which they consider, demonstrate the effectiveness of milk cultures of *B. bulgaricus* in this disease.

The treatment of fowl cholera with quinin, HALLENBERGER (*Arch. Schiffs u. Tropen Hyg.*, 17 (1913), No. 13, pp. 466, 467).—The author has found the injection of 0.5 gm. quinin bimuriate to give good results both as a therapeutic and prophylactic agent.

A list of current medical periodicals and allied serials (*Chicago: John Crerar Library*, 1913, 2. ed., pp. 32).—A list of medical periodicals which deal both with human and veterinary medicine.

RURAL ENGINEERING.

Irrigation from reservoirs in western Kansas and Oklahoma (*U. S. Senate*, 62. Cong., 3. Sess., Doc. 1021, 1913, pp. 54, pls. 8, figs. 10).—This document, prepared by R. D. Robertson and S. T. Harding, reports investigations of the feasibility and economy of irrigation from reservoirs in the 18 western counties of Kansas and the 2 western counties of Oklahoma, lying west of the line of 20 in. mean annual rainfall. A general reconnaissance was made, and 5 sites, 2 of them large, were surveyed in Kansas.

It is concluded that while neither time nor funds were available for a thorough investigation of the storage possibilities of these 2 sections, such opportunities as were found for irrigation development by storage are not promis-

ing, and considered in relation to the total agricultural area the total acreage which can be supplied with water will never be more than a very small percentage of the available land. The general irregularity and torrential character of the flow of streams make it practically necessary to store on the stream beds, and with the small and unsatisfactory supplies that are found on all but 1 or 2 of the streams, proper development of sites can not be considered practical.

High-land pumping plants are being installed in the Arkansas Valley from which the annual cost of water will be in excess of \$10 per acre so that for such pumping to be profitable the best agricultural use must be made of the land. The small windmill or other pumping plant with storage reservoir or the small reservoir to store sufficient storm run-off to supply the garden products and trees is the class of irrigation development which is deemed the most promising for this area in general, although attempts to irrigate more than enough crops for home consumption by this method have not been generally successful. The most significant new development now taking place is the pumping from the underground waters on the uplands with lifts of over 100 ft.

Hydraulic laboratory for irrigation investigations, Fort Collins, Colo., V. M. CONE (*Engin. News*, 70 (1913), No. 14, pp. 662-665, figs. 5).—A description is given of the most important features of the new hydraulic laboratory, constructed under a cooperative agreement between the irrigation investigation division of this Office and the Colorado Experiment Station, for the purpose of testing and determining the accuracy of various water-measuring devices and supplying correct formulas for their use.

Report of the water rights branch of the department of lands (*Rpt. Water Rights Branch Dept. Lands, Brit. Columbia, 1912, pp. 120, pls. 14, figs. 22*).—This report contains the following articles pertaining to water supply and irrigation: Irrigation's Part in the Future Upbuilding of British Columbia, by S. Fortier (pp. 10-14); Water Legislation and Administration in British Columbia, by H. W. Grunsky (pp. 15-23); Shall Water Licenses be Perpetual? by O. C. Merrill (pp. 23, 24); Collection and Filing of Hydrographic Data, by E. Davis (pp. 25-28); Water-power Investigations in the Columbia River Drainage Basin—Progress Report, by G. G. Donald (pp. 31-40); Description of Work at Hydrographic Station near Nelson, by H. F. Meurling (pp. 41-43); Suitable Designs for Small Headgates, by F. C. Scobey (pp. 44-48); Watersheds of British Columbia—Characteristics and Possibilities, by H. W. Grunsky et al. (pp. 49-100); Forms used under the "Water Act" (pp. 100, 102); and Forms proposed by S. Fortier and H. W. Grunsky (pp. 103-105).

A study of irrigation heads in the Modesto and Turlock irrigation districts, California (*Engin. News*, 70 (1913), No. 11, pp. 502, 503).—Studies of volumes of water in second-feet delivered to each individual irrigator and of the time the head is used per acre of land were made by P. C. Berkefeldt in these districts, where alfalfa is the principal crop raised. A summary of the conclusions as to the best practice in both districts is as follows:

The strip system of checking is the cheapest and most economical of water where the topography will permit its use, otherwise a combination of square and strip checks is best. The best width of strip check is from 50 to 75 ft., the best length about 600 ft., and the best grade from 2 to 4 in. per one hundred feet. Farmer's ditches should have at least 6 ft. bottom width with gates the same width. For fairly sandy and sandy soils the use of a larger head for a shorter period of time is best for alfalfa; on the average, not less than 15 second-feet head for from 20 to 30 minutes per acre, irrigating one check at a time. For trees, vines, etc., in the same soil about 5 second-feet for an hour

per acre is best, irrigating 3 or 4 rows at once. Water should be applied directly to each check from the ditch and the water surface in the ditch should be at least 1 ft. above the highest check.

Derivation of run-off from rainfall data, J. D. JUSTIN (*Proc. Amer. Soc. Civ. Engin.*, 39 (1913), No. 6, pp. 1211-1228, pl. 1, figs. 20).—In an attempt to develop a rational method of deriving run-off from rainfall data on various watersheds the author found that on the watersheds examined the relation may be expressed by the formula $C=KR^2$, in which C is the annual run-off in inches, R the annual rainfall in inches, and K is a constant depending on the variations in the relations between rainfall and run-off from one watershed to another, depending on slope and mean annual temperature. Comparisons of numerous watersheds also indicated that the relation of run-off to rainfall may be expressed by the general formula $C=0.934 \frac{S^{0.155}}{T} R^2$, in which T is the mean

annual temperature and S the slope of the watershed (the difference between the highest and lowest elevations divided by the square root of the area).

Numerous rainfall and run-off curves and tables of data are presented to substantiate this view, and tables are given to aid in the solution of the formula. The author believes this formula to be applicable to watersheds in the eastern United States and suggests its use, in that part of the country, where run-off data are meager or lacking.

Seepage losses from earth canals, E. A. MORITZ (*Engin. News*, 70 (1913), No. 9, pp. 402-405, figs. 2).—This article considers the so-called nonpreventable losses from seepage or percolation through the bed or banks of earth canals, and presents figures said to represent the average results obtained from observations on several hundred miles of canals on 8 different reclamation projects to express the losses in terms of depth in feet in 24 hours through the wetted perimeter of the canal prism as follows: Cement gravel and hardpan with sandy loam 0.34 ft., clay and clay loam 0.41 ft., sandy loam 0.66 ft., volcanic ash 0.68 ft., volcanic ash with some sand 0.98 ft., sand and volcanic ash or clay 1.20 ft., sandy soil with some rock 1.68 ft., and sandy and gravelly soil 2.20 ft. It is concluded that the limits within which seepage losses should be considered in earth canal design may be generally defined as 0.5 ft. and 2.5 ft. per 24 hours over the wetted area of the canal.

From a mathematical consideration of seepage losses the following equation is derived: $s=0.2 c \times \frac{Q^{\frac{1}{2}}}{V^{\frac{1}{2}}}$, in which s is the seepage loss in second feet per mile of canal, Q the canal discharge, V the mean velocity of flow, and c an experimental coefficient equivalent to the depth of water in feet lost over the wetted area in 24 hours.

A diagram platted from results obtained from this equation, using values of c varying between the above prescribed limits, is given. This shows the effect of variations in velocity on these results and the advantages of using as high velocities as possible. The magnitude of the error claimed to be involved in stating the seepage loss in percentage of the flow is also illustrated.

The development of balancing devices for centrifugal pumps, A. V. MUELLER (*Engin. News*, 70 (1913), No. 11, pp. 490-494, figs. 21).—Several devices for caring for the axial thrust of the shaft in centrifugal pumps are described and their design analyzed. Both partial and complete balance devices are dealt with, and it is stated in conclusion that entirely automatic devices have the advantage over incompletely balanced devices in that they rid the pump of such members as marine thrust collars, ball bearings, etc., which are a constant source of trouble.

Construction of concrete pipe lines, B. A. ETCHEVERRY (*Jour. Electricity*, 31 (1913), No. 6, pp. 128, 129, fig. 1).—This article gives data on making, hauling, trenching for, and laying cement pipe, including tables of cost of this work on several private irrigation projects.

Large clam shell dredges; levee building methods and standards in California, F. H. TIBBETTS (*Engin. News*, 70 (1913), No. 10, pp. 456-459, figs. 8).—This article describes dredging machinery developed to meet conditions in land reclamation in California. Cross sections of levees are given and methods of flood control of the Sacramento River described.

A study of the comparative economy and convenience of steam operated and electrically operated pumping plants for drainage (*Engin. and Contract.*, 40 (1913), No. 14, pp. 371-374).—An abstract of a paper read before the fourth meeting of the Association of Drainage and Levee Districts of Illinois, which contains an argument for the use of electric power for operating drainage pumping plants and assembles and states considerable comparative data on pumping costs and efficiencies.

It is concluded, since the total cost of steam pumping in well-designed plants closely approximates \$1.25 per acre per year, that with electrical energy at 4 cts. per kilowatt hour the total cost of electric pumping does not exceed that of steam pumping, and has many advantages over other kinds of power from the standpoint of actual economy, efficiency, and convenience in operation.

Ground water movements, drainage methods, and open channel drainage, L. SCHMEER (*Engin. and Contract.*, 40 (1913), No. 13, pp. 349-353, figs. 9).—This is a study of open ditch land drainage in which the movement of water in various soils is considered and hydraulic formulas derived for estimating the probable flow from water-bearing soils into ditches, tunnels, infiltration galleries, or wells. Considerable data are given for designing drainage channels to meet various conditions of topography, rainfall, run-off, and soil porosity, and reference is made to various drainage areas.

Land drainage in Louisiana, A. M. SHAW (*Engin. News*, 70 (1913), No. 7, pp. 300-303, figs. 6).—This article describes the reclamation of timber swamps and prairies which are some distance back from the river, levee construction on trembling prairies, types of dredging plants, including dipper, orange peel, and hydraulic dredges, and the use of power plows for excavating drainage ditches.

The drainage of Lower Egypt, W. WILLCOCKS and M. V. MOSSERI (*Cairo*, 1912, pp. 11, pl. 1).—It is stated in this pamphlet that the effective drainage of Lower Egypt is impossible without pumping and that this pumping can best be done by the Government. Pumping drainage projects in this locality are described with cost data of operation.

Drainage and purification of the soil, R. GAGEY (*Bul. Dir. Gén. Agr. Com. et Colon. Tunis*, 17 (1913), No. 67, pp. 46-93, figs. 47).—This article deals with various methods of disposing of excess surface and underground water as practiced in Tunis, describes several typical drainage and land improvement projects in that country, and notes briefly the local drainage laws.

Text-book on highway engineering, A. H. BLANCHARD and H. B. DROWNE (*New York and London*, 1913, pp. XIII+762, pls. 4, figs. 233).—The authors have attempted in this work to give sufficient details to acquaint the student thoroughly with the principles and practice of modern highway engineering, and in addition to make it sufficiently broad in its scope and content with reference to materials, construction, maintenance, specifications, and cost data to serve as a comprehensive reference book upon the subject of highway engineering for the experienced engineer. The subject matter is presented under the

following chapters: Preliminary investigations; surveying and mapping; design; drainage; foundations; earth and sand-clay roads; gravel roads; broken stone roads; bituminous materials; dust prevention by the use of palliatives; bituminous surfaces; bituminous gravel and bituminous macadam pavements; bituminous concrete pavements; sheet asphalt and rock asphalt pavements; wood-block pavements; stone-block pavements; brick pavements, concrete pavements, miscellaneous roads and pavements; street cleaning and snow removal; car tracks; pipe systems; comparison of roads and pavements; sidewalks, curbs, and gutters; bridges, culverts, and guard rails; and economics, administration, and legislation.

Hard roads in Wayne County, Michigan (*Engin. Rec.*, 68 (1913), No. 13, pp. 340-342, figs. 8).—A more complete description of this work, which has been previously noted (*E. S. R.*, 27, p. 789), is given, including a note on Michigan road laws, data on concrete road specifications, and details of methods of construction.

Asphalt paving cements and road binders, J. W. HOWARD (*Engin. Rec.*, 68 (1913), No. 13, pp. 345-347).—In pointing out the necessary qualities of asphalt paving cement and road binders and describing laboratory methods for determining them, the author claims from his experience that specifications containing tests for gravity, fixed carbon, paraffin, etc., and only parts of the standard and useful tests are directly in favor of certain limited asphalt products and exclude others which may be as good or better. He advocates as the basic and essential qualities, which should be specified, the following: Adhesiveness, waterproofness, immutability, cohesiveness, ductility, flexibility, malleability, consistency at mean weather temperature, minimum susceptibility to extreme weather temperatures, purity, and freedom from injury by necessary melting heat.

Puzzolan mixtures tested for Oregon roads, E. H. McALISTER (*Cement Era*, 11 (1913), No. 10, pp. 66, 68).—Tests of various blends of Portland cement and Oregon puzzolans made by the author in an attempt to reduce the cost of concrete roads in that State indicate that a commercial product of excellent quality may be produced if puzzolan material is reground with cement 1:2 by weight. Comparative cost data show a great saving in favor of puzzolan mixtures if used on a large scale.

Road rollers in the Netherlands, L. C. STEFFELAAR ET AL. (*Internat. Assoc. Road Cong.*, III. Cong. [London], 1913, [Pub.] 73, pp. 25, figs. 10).—This pamphlet deals with road rollers and road rolling in the Netherlands, giving descriptions of a few modern horse-drawn road rollers and their accessories. These are followed by a discussion of the differences in first cost and cost of maintenance between roads which are rolled and roads not rolled, including tables of cost data from the use of horse and steam engine drawn rollers.

The advantages claimed for a modern horse-drawn roller owned by a department are as follows: It can be used in places and under conditions impossible for an engine-drawn roller, is always available at favorable periods, can be profitably used on road improvements of minor importance and on continuous maintenance of roads, and the purchase price is comparatively small. The principal disadvantages are that the road surface is injured by the horses' hoofs, the work is slower than with a traction engine, and good horses are not always available at a reasonable price.

Tests on small gasoline engines, F. M. and E. A. WHITE (*Power*, 38 (1913), No. 9, pp. 299-301, figs. 5).—Tests were made to determine the fuel consumption, in pounds per horsepower hour for varying loads, of 12 small farm internal combustion engines using gasoline as fuel. Three general classes of 4 engines each were made, ranging in power from 3 to 4½, 5 to 7, and 8 to 10 h. p. and

classified as 3, 6, and 10 h. p. sizes. With 1 exception 1 engine of each class was obtained from the same manufacturer and each engine was tested under no load, $\frac{1}{4}$, $\frac{1}{2}$, $\frac{3}{4}$, and full load.

The engine details and the test data are given in tabular form. The cost of fuel per brake horsepower was estimated on the basis of gasoline costing 16 cts. per gallon. The length of time for each test depended upon the time required to bring the fuel consumption approximately constant. At no load this occurred in about 90 minutes, at quarter load after 75 minutes, at one-half load after 60 minutes, at three-quarter load after 45 minutes, and at maximum load after 15 minutes. The fuel consumption became constant before the temperature of the jacket water.

Curves showing the fuel consumption at various loads for each class indicate that for the 3 and 5 to 7 h. p. engines the economy was greatest at the three-quarter load while for the 8 to 10 h. p. engines it was secured at the maximum loads. Curves showing total fuel, minus that at no load, indicate that up to three-quarter load the friction load of the engine is the chief factor in determining the fuel economy. The 3 and 5 to 7 h. p. classes showed that from three-quarter to maximum load other factors entered which caused a very rapid increase in the fuel consumption per horsepower hour while the 10 h. p. class showed little increase.

In determining economical sizes for given horsepowers, curves showing the fuel consumption at different loads for different cylinder displacements, which correspond to the 3, 6, and 10 h. p. classes, indicate that from 1.7 to 3 h. p. the engines having a piston displacement of 90.4 cu. ft. per minute were as economical as those having a piston displacement of 55.7 cu. ft. per minute, and that the larger displacement was more economical from 3 to 4 h. p. From 4 to 6.75 h. p. the engines having an average displacement of 90.45 cu. ft. per minute were more economical than those having a displacement of 125.4 cu. ft. per minute, but from 6.75 to 10 h. p., the larger displacement was most economical.

It is concluded that from 1 to 6.75 h. p. the engine having a displacement of 90.4 cu. ft. per minute corresponding to a rated 6 h. p. engine is, so far as economy in fuel consumption is concerned, the most desirable engine. For horsepowers above 6.75 the engine having a piston displacement of 125.4 cu. ft. or the 10 h. p. engine, would be the most desirable.

A new method of cooling gas engines, B. HOPKINSON (*Gas Engine*, 15 (1913), No. 10, pp. 568-575, figs. 2; *Power*, 38 (1913), No. 10, pp. 332-334, fig. 1).—It was found that by injecting cold water in comparatively coarse jets against the internal surface of a gas engine cylinder and the piston head the metal can be kept cool without materially cooling the gases. Other experiments showed that for practical purposes the heat flow into the barrel of the cylinder during the last three-fourths of the expansion stroke was very small compared with that in the first period, so that it was necessary only to direct the spray against the walls in the combustion chamber and the piston, the rest of the cylinder being cooled by conduction. Results of actual tests verify these claims, and it is concluded that the economy is unaffected by the use of this method of cooling since there is no apparent loss in efficiency.

A traction engine whose four wheels are driving wheels (*Engin. and Contract.*, 40 (1913), No. 7, pp. 172, 173, fig. 1).—A novel traction engine is described which has all 4 wheels the same size and each wheel carrying one-fourth the total weight of the engine. The power plant is a self-balanced 2-cylinder, 4-cycle engine. The transmission is through a pinion and large cut gear to a cast-steel gear case under the center of the frame, from which the

power is transferred by chain drive to differentials on both rear and front axles.

It is claimed that this tractor is very economical in fuel consumption and is able to operate under conditions impossible for the use of the ordinary tractor.

Trials with liquid manure spreaders, M. DALL and C. L. FEILBERG (*Tidsskr. Landökonomi*, 1912, No. 7, pp. 404-433, figs. 12).—Trials with 18 different sprinkling carts are described, and the strong and weak points of each machine are discussed.

The trials of corn and seed drills, 1912, C. P. HALL (*Jour. Roy. Agr. Soc. England*, 73 (1912), pp. 358-365, figs. 4).—The drills were tested in 2 classes: Class 1, drills for corn and pulse, and class 2, drills for grass and clover, coulter and broadcast.

Eight machines were entered in the first-class trials and thoroughly tested for ease and accuracy of adjustment, even distribution of seed, adaptability to various seeds, weight, simplicity of construction, combined with strength, number of attendants, general efficiency, and price. A 13-row and a 12-row corn and seed drill, both of the same manufacture, were awarded first and second honors, respectively.

Only one machine, which was of the same make as the winners of the first-class trials, was entered in the second-class trial. It effected such satisfactory drilling by rows and by broadcasting that it was given first honors, regardless of the absence of competition.

In these trials recent improvements of the various parts apparently displayed no great advantages. The disk type of coulter was classed as no improvement, and the old-fashioned cup feed demonstrated its superiority over all new types. The results in general indicate that the machines tested are far from perfect, and it is stated that a comparison of results obtained in these trials with similar trials held in 1874 shows little improvement and practically no alteration.

Grain cleaning contest (Canad. Thresherman and Farmer, 18 (1913), No. 8, pp. 39, 40, figs. 4).—Three types of grain cleaners were entered in these tests, including 8 machines, 6 of them hand driven and 2 power driven. Wheat, oats, barley, flax, and timothy were used in the tests.

Considering power acquired, capacity, design and construction, and efficiency, the highest score attained out of a possible score of 500 points was 391 points for the hand-driven machines and 411 points for the power-driven machines. Out of a total of 175 points on efficiency, including percentage of waste grain and grain grading, the same machines attained the highest score of 135 points for the hand machine and 132 points for the power machine.

Test of a feed-grinding and sifting mill, J. REZEK (*Mitt. Landw. Lehrkanz. K. K. Hochsch. Bodenkul. Wien*, 1 (1913), No. 4, pp. 558-589, pl. 1).—A brief description of the mill and its adjustable parts is followed by the results of tests.

The mill was driven by an electric motor. Barley containing 12.39 per cent moisture and weighing 70.9 kg. per hectoliter (about 55 lbs. per bushel) was ground to a fine meal at the rate of 246.3 kg. per hour, the speed being 581 r. p. m., and the necessary horsepower 3.13. Oats containing 11.88 per cent moisture and weighing 51 kg. per hectoliter was ground at the rate of 310 kg. per hour, the speed being 614 r. p. m., and the necessary horsepower 1.45. Corn containing 14.39 per cent moisture and weighing 75.8 kg. per hectoliter was ground into 3 sizes by 3 different adjustments, the first yielding coarse meal at the rate of 527.7 kg. per hour, the second a somewhat finer meal at the rate of 365.4 kg. per hour, and the third a very fine meal at the rate of 197.1 kg. per hour, at respective speeds of 618 r. p. m., 614 r. p. m., and 602 r. p. m., and respective necessary horsepowers of 1.05, 2.6, and 2.15.

The sifters were thoroughly tested in connection with the mill by grinding and sifting rye containing 13.89 per cent moisture and weighing 70.9 kg. per hectoliter. Four sifters were used in the following order: A No. 20 with 26 wires per 26 mm., 2 No. 8 with 34 wires, and a No. 9 with 38.5 wires. This test was run under 3 different adjustments and speeds, yielding flour, coarse meal, and bran in varying quantities. The results indicate that the most satisfactory speed for this purpose is between 560 and 570 r. p. m. With the same arrangement 25 kg. of hulled rye underwent a similar process for 1 hour and 14 minutes. Within 17 minutes the yield was as in the first 3 tests. After 48 minutes more, 11.68 kg. of fine medium white flour and 4.50 kg. of fine black flour had been yielded. At this point the following arrangement of sifters was substituted: A No. 18 sieve, with 18 wires per 26 mm., a No. 8, a No. 9, and a No. 5, which contained 1 wire per mm. Within 7 minutes the remainder of the rye was reduced to 1.24 kg. of fine flour, 2.13 kg. of coarse flour, 4.48 kg. of fine bran, and 0.145 kg. of coarse bran. The maximum horsepower required in this test was 3.3 and the average 1.8, and the average power consumption was 2.2 h. p. hours.

Diagrammatic plans of the mill are given with curves of the test results.

The effect of saturation on the strength of concrete, J. L. VAN ORNUM (*Proc. Amer. Soc. Civ. Engin.*, 39 (1913), No. 6, pp. 1229-1236, fig. 1).—Results of several series of tests on concrete specimens, both plain and reinforced, indicate a rapid decrease in strength for the first 2 days of submergence and a systematic increase in strength thereafter. Specimens stored for 38 days in air underwent a rapid decrease in strength when placed in water for 2 days or less but increased in strength after saturation was complete.

Test of pressure of wet concrete, E. B. GERMAIN (*Engin. News*, 70 (1913), No. 7, pp. 294, 295, figs. 2).—A recent test of the pressure of wet concrete to determine the proper figures to be used in the design of forms was made on small area columns where a high head could be produced in a short time. The apparatus used consisted of an ordinary hot-water bag filled with water, a test tube containing mercury inside the bag, and a hollow glass column running from below the surface of the mercury in the tube through a rubber stopper in the neck of the hot water bottle. Six of these bags were placed in each of 2 columns, 20 in. square and about 20 ft. high, and the mercury levels read on each after the column was filled, the difference in levels of the mercury in the test tube and in the column giving the pressure in inches of mercury.

Using a mixture of $1:1\frac{1}{2}:3$, the pressure per square inch was 460 lbs. with a head of 3.08 ft., 900 lbs. for 6.08 ft., 1,330 lbs. for 9.08 ft., 1,710 lbs. for 12.08 ft., and 2,110 lbs. for 15.08 ft. With a mixture of $1:1:1$ the pressure was 407 lbs. for 2.75 ft., and 840, 1,280, 1,700, 2,080, and 2,450 lbs., respectively, for heads of 5.75, 8.75, 11.75, 14.75, and 17.75 ft.

Since the first concrete put in begins to set before the last concrete is poured, the pressures in the lower part of the columns do not show quite full liquid pressure.

Tests of reinforced concrete buildings under load, A. N. TALBOT and W. A. SLATER (*Univ. Ill. Engin. Expt. Sta. Bul.* 64, 1913, pp. 104, figs. 75).—This bulletin records the results of field tests made on 3 reinforced concrete floor systems, 2 of the beam and girder type and 1 of the flat slab type. In addition is included a discussion of the method of testing, the use of the instruments, methods of observation, precautions to be taken, accuracy of results, and methods of loading.

No specific conclusions are drawn because of the wide scope of the tests.

Constructing a silo roof of concrete (*Building Age*, 35 (1913), No. 8, pp. 367, 368, figs. 4).—The construction of a conical reinforced concrete silo roof is

described in which a 1:2 sand and cement mortar is placed on expanded metal reinforcing having not less than a 3 in. mesh. A roof thickness of 2 in. is deemed sufficient for diameters of silos up to 10 or 12 ft. and 3 in. for diameters up to 20 ft. The vertical roof load is converted into tension at the circumference, which is taken care of by horizontal circular reinforcing. Tables are included for reinforcing both monolithic concrete and concrete block silos.

The pit silo for western Kansas, C. McKEE (*Agr. Ed. [Kans. Agr. Col.]*, 5 (1913), No. 14, pp. 12, figs. 2).—It is the purpose of this bulletin to point out to the dry-land farmer of limited means in western Kansas the possibilities of the pit silo and to give directions for its construction.

The essentials of a good pit silo are briefly summarized as follows: The silo must be located in firm, dry, and well-drained soil, and must have a curb extending a few inches above ground and a little below frost line. The walls should be absolutely perpendicular and smooth, plastered from $\frac{3}{4}$ to 1 in. thick, washed with a cement coat to make them air and water tight, and if they become dry before plastering they should be sprinkled lightly. A covering must be provided to keep out dirt, animals, etc., and to provide for free air circulation.

It is claimed that the pit silo is cheap, easily constructed, does not require a silage blower, and will not blow down. The silage will not freeze and will keep well if properly distributed and packed. No large cash outlay is necessary and no expensive forms are required in construction.

Farm water supplies, pumping machinery, and accessories, W. HOFFMANN (*Ztschr. Landw. Kammer Schlesien*, 17 (1913), Nos. 34, pp. 1205-1212, fig. 1; 35, pp. 1260-1265, figs. 9).—This article deals with the importance of pure water supplies for the farm and methods for obtaining it, and gives suggestions for determining the size of supply, specifications for piping and other conveying and distributing accessories, and directions for obtaining surface supplies and deep and shallow well and spring supplies. Descriptions of the construction and operation of hydraulic rams and types of small deep and shallow well pumps are given with instructions for their installation and use. In determining the size of supply it is suggested that for all purposes each person be allowed per day 20 liters, each horse 55 liters, each cow from 60 to 80 liters, each ox 70 liters, each calf 30 liters, each sheep 5 liters, and each pig from 20 to 80 liters.

Shower bath for country houses, C. Fox (*Pub. Health Rpts. [U. S.]*, 1913, Sup. 7, pp. 4, fig. 1).—A serviceable and inexpensive shower bath is described and illustrated for use in houses where there is no running water. It is made from a tin can such as is used in shipping kerosene or turpentine. The solder around the upper edges of the tin is melted off and the top removed. To the bottom are attached a stop cock and a shower head about 6 in. in diameter with very small outlet holes. The tin is lowered and raised by a rope running through a pulley attached to a rafter or other convenient support.

RURAL ECONOMICS.

A questionnaire on markets, J. W. FARLEY (*Ann. Amer. Acad. Polit. and Soc. Sci.*, 50 (1913), No. 139, pp. 139-152).—This article gives a list of 43 questions submitted to those in charge of the markets of 12 cities and summarizes their answers. The questionnaire covered the history, expense, sources of revenue, influence on producer and consumer, and other questions pertinent to city markets.

Some typical American markets.—A symposium (*Ann. Amer. Acad. Polit. and Soc. Sci.*, 50 (1913), No. 139, pp. 118-138).—This symposium comprises (1) Baltimore's Markets, by J. F. Thrift and W. T. Childs; (2) Municipal Markets

in Cleveland, by C. Kamp; (3) The Indianapolis Market, by A. Burk; (4) The Milwaukee Municipal Market, by L. Tiefenthaler; (5) Municipal Markets in Philadelphia, by A. Lippincott; and (6) The Rochester Public Market, by W. W. Merrill.

C. L. King outlines the purpose of this symposium and enumerates the principal points taken up by each of the other authors, such as the character of the market, charges, regulations, extent of use by farmers, encouragement given to farmers, effect of the market on prices, and the effect of marketing on the surrounding country. The other authors describe the conditions of the market in their city with these suggestions in mind.

Cleveland's retail markets, C. G. CARPENTER (*Agr. Student*, 20 (1913), No. 2, pp. 127-129, fig. 1).—The author describes the market conditions in Cleveland and concludes that the real value of the public market is that it furnishes a means of distributing the fresh products of the farm and garden to the most people at the lowest cost of distribution.

Car-lot markets and how they are supplied, F. ANDREWS (*Ann. Amer. Acad. Polit. and Soc. Sci.*, 50 (1913), No. 139, pp. 1-9).—The author states that the more perishable of farm products give rise to special market problems. Some of those mentioned are the size of market, the location of market places, the sources of supplies, the methods used to obtain car-lot shipments, the handling of cars in transit, and the value and difficulties of various systems of market news.

Markets for American fruit (*Spec. Cons. Rpts. [U. S.]*, 1913, No. 62, pp. 54).—This abstract contains reports from consuls located in 23 foreign countries showing market conditions, tariffs and other regulations, prices, and source of supply of fruit. These reports are taken from replies to inquiries sent out at the request of the Pacific coast fruit growers' associations.

Prevention of waste and seasonal price fluctuations through refrigeration, G. K. HOLMES (*Ann. Amer. Acad. Polit. and Soc. Sci.*, 50 (1913), No. 139, pp. 48-56).—The author gives a summary of the results and the methods used in his investigation for the U. S. Department of Agriculture of the influence of cold storage on prices. See also previous notes (E. S. R., 28, pp. 871, 872).

The motor truck as an agency in direct marketing, S. A. PHILLIPS (*Ann. Amer. Acad. Polit. and Soc. Sci.*, 50 (1913), No. 139, pp. 20-34).—The author concludes that the motor truck offers the farmer a wider sphere of activity, a choice of crops, markets, and buyers, lowers the haulage of cost, and will enable him to develop more remote and unproductive lands.

The Long Island home hamper, H. B. FULLETON (*Ann. Amer. Acad. Polit. and Soc. Sci.*, 50 (1913), No. 139, pp. 166-170).—This article narrates the methods used to distribute market garden produce directly from the producer on Long Island to the consumer in New York City.

The cooperative lamb club as an agency for lower marketing costs, D. H. DOANE (*Ann. Amer. Acad. Polit. and Soc. Sci.*, 50 (1913), No. 139, pp. 216-222).—The author states that by forming an association at Goodlettsville, Tenn., the farmers were able to grade their lambs better and obtain a considerable advance over what they had been offered previously by local buyers.

An inquiry into agricultural credit and agricultural cooperation in Germany, J. R. CAHILL (*London: Bd. Agr. and Fisheries*, 1913, pp. XXXVI+302+226, pls. 2).—Under mortgage (long-term) credit the author describes in detail the land mortgage credit associations (*Landschaften*), state and provincial mortgage credit banks, joint stock mortgage banks, savings banks, credit for land improvement, Prussian provincial aid banks, rent charge banks, and insurance institutions and agricultural credit.

He concludes that the organization of institutional mortgage credit in Germany has been greatly facilitated by its complete system of registration of title and by the clearness of its mortgage law. Compulsory registration of title, as it exists in Germany, Austria, Hungary, and Russia, or, at least, compulsory registration of deeds (as in France, Belgium, Holland, and other European countries, as well as in America and British India), appears an indispensable prerequisite for the foundation of a system under which landowners may obtain mortgage credit on suitable terms by the issuing of land bonds which would rank as first-class securities in the general market.

Under personal (short-term) credit he discusses local cooperative banks and central cooperative banks. He considers that the growth of the personal-credit idea has been the result of necessity. Individual small farmers must rope themselves together with a more or less stable bond in order to be able to present to renters and depositors a security which the latter can accept. The highly localized character of these organizations enables the members to know the trustworthiness and the business capacity of the borrower.

The principal types of cooperative agricultural societies are discussed, and the author claims that as a result of land reform a large number of small farms came into existence. In order to hold their own with the larger farmers they were compelled to adopt modern methods of intensive farming, employ manures, buy feeding stuffs, modern implements, and machinery, obtain suitable breeding stock, and put their produce on the market in sufficient and graded quantities without the incurring of undue cost. Because of these circumstances they were compelled to unite into a local cooperative society that was binding upon the individual members only as regards the particular objects aimed at by the organization. Thus the different types of cooperative societies had their origin.

In addition, the author describes the method of audit and inspection, and gives as an appendix to his report copies of laws and documents for practically all the kinds of organizations mentioned in his detailed statement. An extensive bibliography of German works on credit and cooperation is included, also a large number of statistical tables.

Cooperative purchase and use of stallions in Denmark (*Jour. Bd. Agr. [London]*, 20 (1913), No. 7, pp. 626-628).—The procedure usually followed in Denmark by an association for the cooperative purchase and use of stallions is described here in detail, with special reference to four associations organized in 1888. The average price of the stallions runs from about £344 to £500. The Government was authorized in 1887 to make grants to horse-breeders' associations to the extent of one-half of the purchase price of a stallion, with a maximum grant per stallion of £222. In 1911 there were 267 associations receiving a total subsidy of £9,360 and owning 281 stallions. The law of 1912 reduced the state subsidy one-half, i. e., the maximum amount for each stallion is now £111.

The experience of animal insurance societies in Holland (*Jour. Bd. Agr. [London]*, 20 (1913), No. 7, pp. 628, 629).—This article presents notes and statistics illustrating the experience of animal insurances societies in Holland in 1911, and makes comparisons with the experience of similar societies in England for the same year.

Some methods of financing the farmer, G. JONES ([*Denver, Colo.*]: *Chamber Com.*, 1913, pp. 16).—The author outlines the two systems of credit found in European countries. Under short-term credit societies he gives some reasons for the low interest obtained in European countries, and suggests some modifications that would make the banking system of the United States more adaptable for this purpose. He also explains the organization of long-term mortgage associations, and considers that the most important factor for facilitating loans

on real estate in Europe is the title registration law which in effect places the Government behind the title to all property.

Rural social development (*Bul. Univ. Wis.*, 1913, No. 591, pp. 130, pl. 1, figs. 22).—The discussions at this conference were under the general topics of better home conveniences, the rural church as a social center, rural social problems, country clubs, and rural social centers. Each topic was treated by three or more persons, each relating in the main his own personal experience.

The farmer's outlook, R. T. HINCKES (*London*, [1913], pp. 140).—The author concludes that the outlook for British agriculture is more promising than for many years past because of the fact that the countries which have been supplying the principal part of agricultural products to Great Britain show a decrease in their exports. He considers that this decline in exports will continue and that the increase from other countries will not be sufficient to meet the future demand, so that the demand for home produce should increase.

Agricultural statistics (*Ann. Rpt. Bur. Indus. Ontario*, 1912, pp. 5-46).—Statistics are given for the Province of Ontario for 1912 relating to the acreage, production, and value of crops, the number and value of live stock, and the number sold or slaughtered. Data are also included relating to weather conditions, the number of butter and cheese factories, and the quantity of milk used and of butter and cheese made.

Agricultural statistics of Ireland, with detailed report for the year 1912, T. BUTLER (*Dept. Agr. and Tech. Instr. Ireland, Agr. Statis. 1912*, pp. XXIV+147).—This report contains statistics concerning the size of holdings, acreage and production of crops, and acreage of pasture, grazing land, and woodland for Ireland and its minor subdivision for 1912.

The introduction contains decennial comparisons showing that between 1851 and 1912 the acreage under cereal crops decreased from 3,099,401 to 1,265,687 acres, and other green crops, including flax, from 1,513,142 to 1,077,151 acres. The acreage devoted to growing hay increased from 1,246,408 to 2,487,349 acres. The number of horses increased from 521,706 to 617,532; cattle from 2,967,461 to 4,848,498; sheep from 2,122,128 to 3,828,829; swine from 1,084,857 to 1,323,957; and poultry from 7,470,694 to 25,525,724.

The number of holdings for the same period of less than one acre increased from 37,728 to 87,451, while those of a larger acreage decreased from 691,202 to 521,345. See also a previous note (*E. S. R.*, 27, p. 796).

Agricultural statistics of Bohemia (*Statis. Handb. Konigr. Böhmen*, 2 (1913), pp. 180-233).—Statistics relating to live stock, acreage and production of farm crops, weather conditions, and forestry are given for 1910, with similar statistics for earlier years.

AGRICULTURAL EDUCATION.

Education for farm life, S. AVERY (*Quart. Rpt. Kans. Bd. Agr.*, 32 (1913), No. 125, pp. 73-82).—In this address the author reviews the progress of education in the United States with special reference to the farmer and its relation to the nation's general economic welfare. He emphasizes the importance of supplying those who are to be farmers with the kind of training that will enable them to become happy, free, and prosperous, and discusses the scope of agricultural instruction in the existing high school, the special agricultural school, and the agricultural college.

[History and growth of the Kansas State Agricultural College] (*Kans. Industrialist*, 39 (1913), No. 33, pp. 8, figs. 17).—An extended account of the history and growth of the Kansas College, prefaced in connection with the recent fiftieth anniversary celebration (*E. S. R.*, 29, p. 698).

The agricultural course for women, GEORGIA E. CANTRELL (*Ann. Rpt. Missouri Bd. Agr.*, 45 (1912), pp. 584-587).—This article presents a brief summary of the agricultural course for women in the University of Missouri, with comments as to the expediency of such a course and the benefits to be derived.

The teaching of entomology in our agricultural colleges, W. LOCHHEAD (*Ann. Rpt. Ent. Soc. Ontario*, 43 (1912), pp. 38-40).—Instead of taking up the chief injurious insects by orders and keeping the relationships of the forms discussed constantly before the minds of the students, the author prefers to deal with them on a basis of their hosts during the first two years or diploma course in Canadian agricultural colleges. In the third year, in which students are preparing themselves to become investigators, teachers, etc., he advocates giving more attention to entomology as a science, this involving some familiarity with the families and chief genera. This he believes can be best acquired by practical work in the laboratory, devoting the fall term to a more detailed study of the anatomy of some typical insects and to a study of the chief families and common genera, and the winter term to a more detailed study of the economic forms. In the entomological instruction of the fourth year, taken by students who are specializing, special problems are assigned for study and discussion, and methods of work and a knowledge of the literature are emphasized. A plan of contents is suggested for a handbook on entomology.

Fit the rural school to the community, ELLEN B. McDONALD (*Business America*, 14 (1913), No. 2, pp. 164-170, figs. 5).—The author discusses the possibilities in the course of study, agriculture in rural schools, agricultural contests, and neighborhood interest.

The betterment of rural schools through agriculture: The Ohio plan, F. W. MILLER (*Addresses and Proc. Nat. Ed. Assoc.*, 50 (1912), pp. 1366-1373).—This paper briefly summarizes the circumstances leading to the passage by the Ohio legislature in 1911 of the act making the teaching of agriculture mandatory in the high and elementary schools of the rural districts and villages of the State. There is also a brief discussion of the manner in which the work has been carried on and its effect on the viewpoint of the average country boy or girl as to farm life.

Industrial education in Columbus, Ga., R. B. DANIEL (*U. S. Bur. Ed. Bul.*, 1913, No. 25, pp. 30, pls. 6).—This bulletin presents a study of the adaptation of the work of the public schools to the conditions and needs of children as being worked out in two schools in Columbus, Ga. Among the special features are the introduction of courses in normal training, home economics, and mechanic arts, industrial work for negroes, a school for children of mill operatives, and an industrial high school.

Household ethics and industrial training in the colored schools of Kentucky, C. L. TIMBERLAKE (*Ky. Dept. Ed. [Bul.]*, 6 (1913), No. 8, pp. 58, pls. 7).—The author discusses the need of instruction in household ethics and industrial training for colored youth, the duties of parents, and lessons in home making, and gives data for use in teaching home economics and agriculture in schools of different grades.

Domestic economy—the family budget, G. FLETCHER (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 13 (1913), No. 4, pp. 735-739).—In this paper, read before the twelfth annual congress of the Irish Technical Instruction Association, Bangor, the author discusses the present status of home economics instruction in Ireland.

Of 112 girls' secondary schools 65 offer instruction in home economics to a total of 1,640 students, and the subject is also taught in every technical school. Outside of large centers there are over 70 itinerant teachers who give

instruction to hundreds of rural centers. The author points out the need of the further extension of this work beyond cookery, laundry work, and needle work, to include systematic instruction in the laws of health, home nursing, and first aid to the injured, and suggests that training for home duties form a part of the education of every girl, and be closely related to her means.

Manual processes of agriculture (*Rpt. Rural Ed. Conf. [Gt. Brit.], 8 (1913), pp. 27*).—As a result of its inquiry into the methods which local education authorities in Great Britain adopt with the object of promoting efficiency in the performance of manual processes, e. g., plowing, hedging, ditching, sheep shearing, milking, and basket making, the Rural Education Conference recommends that (1) instruction in certain manual processes should be provided for the older boys and girls attending elementary schools in rural districts, and that (2) local education authorities and managers of rural elementary schools should regulate the holidays so as to leave the boys free to work on the land at a time when their work is most useful.

For boys and men employed upon the land it is recommended that classes in manual processes should be conducted more in the nature of assistance to rather than formal instruction of those who attend, and the interest and sympathy of the farmers in this work should be secured. Such instruction should be more generally provided by local education authorities throughout England and Wales, and the courses at present provided in most counties should be made more thorough. Local authorities should offer certificates to be competed for by the students at the end of the class, and local societies which organize classes and competitions in manual processes should be encouraged and assisted by local education authorities, although expenditure by local education authorities on money prizes should be regulated.

The methods employed by local education authorities for giving instruction in manual processes at farm schools or agricultural colleges, by itinerant instructors, and through local agricultural societies are outlined, including the duration and subjects of instruction, competitions, and cost of instruction. In half the counties of England and Wales no provision is made by the local education authorities for instructing agricultural laborers in manual processes. Appendixes are added containing summaries of evidence as to the value of instruction in manual processes in the counties in which it is being provided and also as to the need for such instruction in counties in which no provision is made for it.

Manual instruction for adults in rural centers, H. GARRETT (*Dept. Agr. and Tech. Instr. Ireland Jour.*, 13 (1913), No. 4, pp. 748-753).—The author describes the methods now generally employed in the teaching of manual work in adult itinerant classes in Ireland, outlines briefly the ground to be covered in the teaching of constructional drawing for farmers which is an advance upon the itinerant work and forms part of a technical school course adapted to the needs of farmers, shows how the work may be arranged into a definite course, and finally indicates the direction which the teaching of construction should take.

Technical instruction in plowing, A. MURRAY (*Jour. Bd. Agr. [London]*, 20 (1913), No. 2, pp. 116-120).—An outline is given of a system of instruction in plowing which has been fostered for several years by the agricultural committee of the Hants County Council. The director of education of the county appoints the instructor and pays all expenses in connection with the classes. In one district last year there were 5 centers of such instruction with an attendance of about 60 pupils, all of whom received a minimum of 12 hours' instruction each. At the close of the instruction a plowing competition is held and prizes are awarded by the county council.

NOTES.

Missouri University and Station.—Farmers' Week at the college of agriculture, January 12-16, brought out a record attendance of 2,287, representing 19 States and 92 of the 114 counties. The enrollment in the regular short courses also set a new record of 329 students from 84 counties and from 7 States outside of Missouri.

The college has arranged a continuous series of 5-day branch short courses, beginning January 5 and continuing for 2 months. Tentative plans are also being made for holding at least two additional courses in March. Lucius F. Childers, professor of agronomy and agronomist at the Idaho University and Station during 1910-1912, has been appointed assistant professor of agronomy for extension work, particularly in connection with these branch short courses.

New Mexico College and Station.—The college is undertaking extension work through short courses for demonstrations and lectures, to be given to a limited number of counties at a nominal expense to cover some of the traveling expenses. These courses will consist of 5 consecutive meetings at a central place, probably extending over a period of 5 weeks and usually with two departments represented at each meeting.

Rupert L. Stewart has resigned as farm foreman and will specialize in farm management at Cornell University. He has been succeeded by Roland Harwell, formerly assistant in irrigation, and subsequently in commercial work.

Cornell University.—A summer term similar to the two winter terms has been established in the college of agriculture. This will extend from about June 8 to September 23 and is intended primarily for advanced undergraduates, graduate students, and instructors from this and other institutions. Its adoption allows the completion of the regular 4-year course in agriculture in 3 years.

According to the *Tribune Farmer*, the college is to cooperate with the New York Central and Hudson River Railroad Company in an agricultural consultation train over portions of its Mohawk, Ontario, St. Lawrence, and Adirondack divisions. No formal lectures will be given, but 2 cars of exhibits from the plant breeding experiments will be shown and instructors accompanying the exhibits will interpret the experiments for the use of the farmer.

Science announces that Dr. J. H. Comstock, instructor and professor of entomology for 39 years, is to retire at the close of the academic year.

Pennsylvania College and Station.—Recent appointments include Fred J. Holben as assistant chemist and E. De Turk (Purdue, 1913) as assistant agricultural chemist, vice C. A. Smith resigned to take up graduate work. J. F. Cox, instructor in soils, has resigned to become instructor in farm crops at the Michigan College.

West Virginia University and Station.—Nat T. Frame, recently county agent at Louisville, Ky., has been appointed state agent in charge of farmers' cooperative demonstration work. R. E. Hunt and I. B. Johnson, assistants in animal husbandry, have resigned, the former to become associate in animal husbandry at the Virginia College and the latter to accept an appointment as county demonstration agent in Indiana.

EXPERIMENT STATION RECORD.

VOL. XXX.

MARCH, 1914.

No. 4.

The remarkable and world-wide increase of general interest in rural life within recent years has led to some very suggestive efforts on the part of educators and others to demonstrate ways and means by which it can be made more attractive. Many of the more pretentious of these attempts have been carried out in Europe in connection with various expositions, but some of them, although designed with special reference to European conditions, contain much that is of significance and interest elsewhere.

Particularly may this be said of the so-called "Village Moderne," which constituted an unusual feature of the International Exposition at Ghent, Belgium, in 1913, and was so successful that it deserves to be called to the attention of all who are interested in these questions. This village was a practical representation of what was regarded as a model rural community. It was designed to bring before the general public, in a comprehensive way, the organization of country life and its possibilities, and to serve as an object lesson of how the farm and village could be made more convenient, more sanitary, and more attractive.

The original conception of the "Village Moderne" is attributed to M. Paul de Vuyst, Director General of the Belgian Ministry of Agriculture and Public Works, and one of the presidents of the general committee to whom the planning and execution of the project was entrusted by the exposition officials. It was in a sense an outgrowth of some of the agricultural exhibits at earlier European expositions. Thus, in 1905, a group of Belgian agriculturists, acting under the initiative of M. de Vuyst, organized a cooperative society and constructed a set of model farm buildings at the Liège Exposition, in which emphasis was placed on such features as sanitation, the lessening of the danger from fires, modern conveniences, and proper lighting and ventilation, as well as on economy in construction. Five years later the idea was further developed along somewhat different lines at the Versailles Exposition, where a large building was constructed dealing especially with the interests of the farmer's wife, and grounds were laid out as vegetable and flower gardens, lawns, etc.

The building was fitted up in model kitchens, dairies, sleeping rooms, and the like, and was utilized for exhibits of improved housekeeping appliances and for practical demonstrations by the faculty and students of various schools of home economics.

Mention may also be made of the model farm house erected at the Dresden Exposition of Hygiene in the interests of attractive and sanitary farm dwellings at moderate cost; the so-called electrical farm at Amiens, devoted mainly to demonstrations of the application of electricity to farm life, but with some attention to improved hygienic conditions as well; the Flemish village erected at the agricultural exposition at Roubaix, depicting chiefly the laborers' cottages of the region, but with exhibits of agricultural machinery and demonstrations of home economics, blacksmithing, and dairying; and the Dutch farm at the International Exposition of Agriculture at The Hague in 1913, which was largely a portrayal of improved methods of cheese manufacture.

The "Village Moderne" at Ghent, however, was a much more comprehensive and elaborate undertaking than any of its predecessors. It extended the entire length of the exposition grounds, occupying a triangular tract of nearly eight acres. This space was utilized as completely as possible for the buildings, grounds, streets, and other equipment of a complete rural village.

The central feature of the village was the public space or common. This was tastefully constructed and contained an artistic fountain, beds of flowers, and a group of statuary symbolizing the productiveness of the soil. The principal buildings fronted on this square, notably the municipal building, or town hall, the church, the village inn, and the residence of the burgomaster, or mayor. Nearby were located the primary school, schools of agricultural mechanics and home economics, the post-office, which included the telegraph and telephone service, a tract of land reserved for out-door gatherings, a blacksmith shop, several stores, and a village creamery; while radiating from it in the usual European fashion were the buildings and grounds of various types of farms. An electric railway entering the square connected the village with the remainder of the exposition and typified its means of communication with the outside world.

Admirable and suggestive as were the conception and general plan of the village as a whole, its success in an educational way was perhaps even more largely to be attributed to the scrupulous attention given to the manifold details and special requirements. For instance, the architectural features received much attention, as it was desired to erect buildings of a type within the reach of rural communities, and which would at the same time be distinctive, attractive, and capable of blending together to form a homogeneous unit. Practical considerations also rendered it necessary that the bulk of the

space within the buildings should be available for exposition purposes, and therefore adaptable to many special needs. In the main, these varied requirements were all met, in many cases in most ingenious ways.

Thus the municipal building, designed to afford a meeting place for the local officials, was utilized as the headquarters of various Belgian officials connected with agriculture, and served to bring their activities into close touch with those in attendance. Attached was a large hall, which was used for exhibits of agricultural interest, a room which was fitted up with a collection of books and pamphlets as a village library, and quarters occupied by a fire department and a health service.

The primary school building and its equipment were designed by the exposition section on instruction, and it is said that to describe them would be merely "to codify the rules which should govern school buildings in rural communities." The plant was planned to accommodate seventy pupils, and included a school garden of one-fourth acre and several formal ornamental gardens. Movable schools of farm mechanics and home economics, such as are sent from place to place in Belgium, were also installed in the village and gave regular instruction to classes and frequent demonstrations for the general public.

Opportunity was also afforded to illustrate a number of semipublic enterprises, such as a cooperative creamery, a blacksmith shop, an inn, and a garage. These, for the most part, were fitted up by private parties, and in some cases operated as commercial undertakings, but all were required to conform to the general plan of the committee in charge.

The most important part of the rural community, however, was recognized to be neither the public buildings nor those of a semipublic nature, but the farms which constituted its very foundation, and it was their architecture and equipment which received the most careful attention. Complete sets of buildings were erected and furnished to illustrate what could be done on the large, medium, and small farm; and in addition there were structures to show the special requirements in horticulture and beekeeping, and a number of the simple cottages designed for farm laborers.

The largest farm group was erected under the direct supervision of the committee, and was planned to show an arrangement of buildings which would effect a maximum economy in manual work and yet provide a convenient and sanitary home of pleasant and attractive appearance. Its equipment was in part supplied by manufacturers, and in part by societies, the family living room, for instance, being most attractively equipped by the federation of clubs of farmers'

wives of the Province of Namur. Similar arrangements were made in the remaining farm groups, although these were on a somewhat smaller scale, one being designed for farms of about 45 acres and the other for the small holding of from 5 to 10 acres. One of the laborer's cottages was constructed and equipped by a building association in Ghent, which specializes in this type of dwelling.

A noteworthy feature in one of the farm groups was the participation of the permanent schools of home economics of Belgium. Some of these furnished the sleeping rooms, another a family collection of medicines, while others exhibited illustrative material dealing with such diverse subjects as family hygiene, floriculture, cookery, stable construction, and dressmaking. By such means, the various institutions were brought prominently before the public in a concrete and interesting way, and a powerful impetus was given to the whole propaganda for agricultural education.

Ideals of practical service and appropriateness joined with esthetic considerations of simplicity, beauty, and good taste characterized the village throughout. Owing to its ephemeral nature, its embellishment was somewhat restricted because of the obvious impossibility of obtaining the full decorative effect from slow-growing trees and shrubs; but, on the other hand, the results secured were the more useful in some ways since they revealed what could be accomplished without great delay. Floriculture was naturally especially in evidence, both in the practical gardens of the individual home and in the more formal and pretentious decorations of the public grounds and buildings. The planning, construction, and lighting of streets and driveways, the fences, and even the form and position of sign posts received the careful and sympathetic treatment typical of the entire enterprise, and contributed appreciably to its symmetry and effectiveness.

Great interest was manifested by the Belgian government in the village from its inception, and this doubtless aided its success in no small degree. The committees having the project in charge were largely composed of Belgian officials associated with agriculture or education, and the various institutions working along these lines cooperated in the enterprise in many ways. About 10,000 square feet of floor space was available in the exposition halls attached to the municipal building, and this was occupied very largely by exhibits of agricultural education, rural associations, and the like. There was also a special building, representing a hunter's lodge, for the exclusive use of the department of waters and forests, in which its various activities were depicted.

The official status of the undertaking, as well as the high regard in which the agricultural industry is regarded in Belgium, was still further attested by a visit from King Albert, who inspected the

village in detail. It is of interest to note that the King expressed himself as most heartily approving the project, and especially its esthetic phases as "a natural movement to uplift the rural population and to stimulate the mind and the heart of the tiller of the soil."

The results of an undertaking of this sort are obviously beyond exact estimation, yet it is difficult to imagine a means which could have been more effective under the conditions. Surely, if "seeing is believing," even a cursory observation of so complete and attractive a spectacle could not fail to make a deep and lasting impression upon large numbers of those who came within its borders, and its psychological influence must have been far-reaching both in time and distance.

At the close of the exposition, a complete descriptive account of nearly 250 pages and plentifully illustrated was prepared and disseminated, and a permanent national commission was organized by those in charge to further in the future the improvement of country life and the beautification of rural communities. This commission has decided to hold a congress to consider these subjects in detail and to foster and extend the awakening public interest along these lines. These measures should do much to extend and perpetuate the influence of the enterprise.

In any event, the benefits accruing should be by no means restricted to Belgium, for while many of the details are necessarily applicable to only a localized area, the fundamental conception of enhancing the attractiveness of rural life is one of world-wide significance and importance. Already, a Swiss village is announced for the national exposition to be held in Bern in 1914, in which the same general principles are to be followed, and in view of its many merits it would seem that the idea could well be considered by those in charge of expositions, state fairs, and similar enterprises elsewhere.

In the United States nothing of precisely this nature has thus far been attempted. Until quite recently, in fact, community development in this country, even in the larger cities, has been in general a somewhat haphazard and utilitarian affair, with too little attention to esthetic considerations for either the present or the future. This is not surprising, because, as compared with Europe, ours is a relatively young country with new sections still developing, with improvements not yet so permanent, and with conditions of life much less rigidly defined. Of late, however, with the passing of the pioneer stages, there have been many indications of an awakening interest in civic improvement in both city and country, and a growing realization of the opportunity for leadership in this direction.

Among the numerous forces which have been identified directly with the improvement of conditions in the open country may be

mentioned the various country life conferences and rural improvement leagues, the recently organized Collegiate Country Life Club for Rural Leadership, and similar organizations. The large amount of attention accorded in recent years to country life matters by the press, especially the magazines, and the activities of educational, religious, and social workers, all reflected in a greater interest and sympathy on the part of the general public, have also collectively exerted a considerable influence in stimulating a desire for rural betterment.

Various special factors, both internal and external, have likewise been at work in many towns and villages, often leading to the formation of village improvement societies or the attempting of similar functions by the grange, church societies, or other local organizations. In the upbuilding of some of the newer sections of the country, the value of well-planned and attractive streets and public buildings as an aid to growth and development has been appreciated from the start by some of their promoters, and where this is true it is resulting in an increasing number of communities of considerable individuality and great charm. Similarly, many of the railway systems have recognized the advantages to all from the enhancing of the appearance of the communities traversed by their lines, and have endeavored to further their development by encouraging their local officials through prizes and otherwise to beautify the grounds around their stations and elsewhere along their rights of way, and in some cases by cooperating with municipalities, boards of trade, and the like in a general campaign of beautification.

Now that this interest has been so generally awakened in one way or another, the urgent need is for trained leadership, and especially of expert advisers capable of formulating a sane and yet comprehensive program. The lack of a suitable plan, with provisions for the future as well as for the present, is coming to be realized as one of the most serious handicaps in improvement work to-day, and one which is by no means confined to rural villages. Many of the agricultural colleges, for instance, are contemplating somewhat ruefully the consequences of their own lack of foresight, and are attempting with considerable expense and difficulty to overcome as far as is now possible the disadvantages they are under, because of having had no adequate plan for their buildings and grounds in the earlier days.

Fortunately, in many of the older parts of this country, notably in New England, the generous commons and broad streets provide an excellent foundation for landscape work, while the very lack of development in the newer sections makes them at least an unspoiled field for future progress. In any case, however, there is need for a definite plan of development, and the value of this plan will be much

increased if it can be prepared by some agency of recognized ability and authority.

Such assistance may appropriately be expected of the various agricultural colleges and it is of interest to note that several of them are already embracing the opportunity. The rural surveys of the universities of Wisconsin, Minnesota, and other States may be mentioned as a useful preliminary step in this direction, as is also a recent bulletin issued by the Wisconsin Station on rural social centers, in which the workings of the rural school, the rural club, the rural church, and the rural municipal center along this line are presented and discussed.

As another instance may be cited the campaign of the New York State College of Agriculture, which, it will be recalled, exhibited at the Fifth National Corn Exposition in 1913 a most suggestive model of a plan for a rural community center. This plan was proposed as a modification of the usual county fair, with a view to eliminating its objectionable features while retaining those which are desirable, and adding new elements which would permit of the plant being utilized throughout the year. Its distinctive features included the use of a tract of land from twenty to thirty acres in extent, in part laid out much as the usual fair grounds, but containing in addition a building available for year-round meetings and exhibits, a grove for picnics and similar gatherings, an athletic field, a consolidated school with gardens, and a considerable area for demonstration plats.

Such a center, it is readily seen, could be made most useful as well as attractive. The entire project need not be carried to completion immediately, but a fundamental requisite to its success is the securing of a suitable tract of land, and usually this may be obtained most easily in the earlier stages of settlement. As a step in this direction may be mentioned the bill passed by the United States Senate in February, under which the Secretary of the Interior is authorized to withdraw from entry suitable tracts on the various reclamation projects in Montana, not to exceed twenty acres in any one township, for the use of residents as country parks, public playgrounds, and community centers.

A number of the agricultural colleges have evinced their interest in rural community improvement through their departments of landscape gardening, and some of these are offering courses with this end in view. Thus, at the Massachusetts Agricultural College there is a course in civic art which includes work in city, village, and rural improvement. As a practical exercise along this line the students recently prepared a working plan for a contemplated project of street improvement in a large nearby city, thereby receiving considerable commendation for themselves and the institution from a com-

munity which had hitherto found little in the work of the college of direct application to its particular needs. The same college has also provided a special extension instructor in civic betterment, working in connection with the landscape gardening department, to give assistance in rural and village improvement enterprises, such as the planting and care of shade and street trees, the planning of playgrounds, cemeteries, and picnic grounds, the beautifying of water fronts, and the arrangement and development of town commons. It is anticipated that much of this work will be conducted in cooperation with local granges, men's and women's clubs, village improvement societies, and similar organizations.

The criticism is sometimes expressed that the agricultural colleges have been too largely concerned with the material problems of farm life, and however this may be, it is certain that they have a legitimate field for leadership through the social forces at work under rural conditions. As Dean Russell of Wisconsin has said, "the problems of agriculture are so intimately and inextricably bound up with those of country life in general that it is well nigh impossible to separate them. In its last analysis, all of the questions that concern us relative to crop production and utilization are only incidental to the more fundamental inquiries regarding country living, for the farm is not only a place of business but a home." If the colleges in addition to increasing the farmer's income can add to the richness and attractiveness of rural life they will have demonstrated anew their right to a position of rural leadership.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

Treatise on general and industrial inorganic chemistry, E. MOLINARI, trans. by E. FEILMANN (*Philadelphia*, 1912, 3. ed., rev. and enl., pp. XVI+704, pls. 3, figs. 280).—The first part of this third edition deals with general chemistry, the second with the nonmetals, and the third with metals, with an appendix which deals with the treatment of water for industrial purposes. The book is plentifully illustrated with cuts and drawings, and discusses many subjects, such as the fixation of atmospheric nitrogen, of interest to the agricultural chemist.

General and industrial organic chemistry, E. MOLINARI, trans. by T. H. POPE (*Philadelphia*, 1913, 2. ed., rev. and enl., pp. XIX+770, figs. 506).—A number of alterations have been made in this English edition, consisting chiefly in amplifications of the statistical data referring to Great Britain and the United States. The first part of the book deals with the general chemistry of organic compounds, while the second portion considers the derivatives of methane and includes the chemotechnical processes concerned in the petroleum industry, the manufacture of alcohol and alcoholic beverages, the preparation of waxes, soap, and sugar, the tartar industry, animal oils and fats, etc. The products belonging to the cyclic compounds are also given consideration.

Allen's commercial organic analysis, edited by H. LEFFMANN, W. A. DAVIS, and S. S. SADTLER (*Philadelphia*, 4. ed., vols. 2, 1910, pp. X+520, figs. 14; 3, 1910, pp. X+635, figs. 25; 4, 1911, pp. VIII+466, figs. 7; 5, 1911, pp. IX+704, figs. 8; 7, 1913, pp. IX+563, figs. 29; 8, 1913, pp. X+696, figs. 60).—This is a new edition of this well-known work, the first and sixth volumes of which have been previously noted (E. S. R., 22, p. 508; 27, p. 806). The topics dealt with are as follows: Volume 2, fixed oils, fats and waxes, soap, glycerol, wool fat; volume 3, hydrocarbons, asphalt, phenols, aromatic acids, modern explosives; volume 4, resins, rubber, gutta-percha, essential oils; volume 5, tannins, dyes and coloring matters, inks; volume 7, alkaloids, animal bases and acids, glucosids, cyanogen; and volume 8, enzymes, proteins, milk, meat, hemoglobin, proteoids, fibroids.

Practical agricultural chemistry, S. J. M. AULD and D. R. EDWARDS-KER (*London*, 1913, pp. XXIV+243, pls. 5, figs. 28).—This book is intended, according to the preface, as an aid to those students working through courses of instruction for the purpose of obtaining the bachelor of science degree of the University of London. Quantitative analytical methods are introduced throughout the work, largely as a means of interpreting principles or expressing ideas and not as an end in themselves. In the work prescribed a knowledge of the more common qualitative and quantitative processes of general chemistry is taken for granted.

Yearly report in regard to the progress made in agricultural chemistry, edited by T. DIETRICH (*Jahresber. Agr. Chem.*, 3. ser., 15 (1912), pp. XXX+

555).—This is the report for the year 1912 in continuation of that previously noted (E. S. R., 28, p. 616).

The chemistry of plant and animal life, H. SNYDER (*New York, 1913, 3. rev. ed., pp. XXII+388, pls. 3, figs. 101*).—The third revised edition of this work, in which an attempt has been made to obtain a sharper division between the first part, dealing with the elementary principles of chemistry from an agricultural viewpoint, and the second section, which treats more distinctively of the chemistry of plant and animal life.

Biochemistry of plants, F. CZAPEK (*Biochemie der Pflanzen. Jena, 1913, vol. 1, 2. rev. ed., pp. XIX+828 figs. 9*).—This, the second revised edition, has been amplified. Its contents include a historical introduction, general biochemistry, special biochemistry of plants, and the lipoids in the plant metabolism.

Micro-chemistry of plants, H. MOLISCH (*Mikrochemie der Pflanze. Jena, 1913, pp. IX+395, figs. 116*).—This publication is divided into a general and a special part. The former deals with methods, apparatus, and general considerations, while the special part is subdivided into an inorganic and organic division. The inorganic portion deals with the cations (iron, aluminum, manganese, calcium, magnesium, potassium, sodium, and ammonium), the anions (sulphates, nitrates, phosphates, carbonates, silicates, chlorine, and iodine), and oxygen. The organic portion deals with the fatty series, the aromatic series (which includes phenols, aldehydes, quinones, terpenes, resins, tannins, glucosids, and coloring matters), the cell membranes, and the inclosures of the nucleus, plasma, and cellular fluid. The book contains a comprehensive bibliography.

Osmotic pressure, A. FINDLAY (*New York, London, and Bombay, 1913, pp. VI+84, pls. 2*).—The contents of this book, which is one of a series of monographs on inorganic and physical chemistry, are as follows: Semipermeable membranes and osmotic pressure; van't Hoff's theory of dilute solutions; direct determination of the osmotic pressure of concentrated solutions; discussion of the recent determinations of osmotic pressure, and of the van't Hoff theory; the general theory of ideal solutions; discussion of the osmotic pressure of aqueous solutions of cane sugar in the light of the theory of ideal solutions; indirect determination of the osmotic pressure; and views regarding the cause of osmosis and the action of the semipermeable membrane. A bibliography embracing 137 titles is appended.

Solvents, oils, gums, waxes, and allied substances, F. S. HYDE (*New York, 1913, pp. VI+176*).—This book consists of a series of notes for the use of factory chemists and those who desire a short reference work on commercial organic products. It includes tests which have been found reliable in the hands of the author. Its contents are as follows: Various solvents and fluids; terpene bodies, camphors, essential oils, fragrant substances, and balsams; true gums, gum resins, and bitumens; carbohydrates; albuminoids and proteids; oils, fats, and waxes; a list of commercial tests on oils and fats; lubricating oils; linseed oil; insoluble soaps; fatty acids; alkaloidal substances; bitter principles; and miscellaneous substances.

The volatile oils, E. GILDEMEISTER and F. HOFFMANN (*Die Ätherischen Öle. Leipzig, 1913, vol. 2, 2. ed., pp. XVIII+713, pls. 5, figs. 53*).—This is the second edition of the second volume of this work, and has been edited by E. Gildemeister. The first volume has been previously noted (E. S. R., 25, p. 113).

Biology of fat decomposition, A. SPIECKERMANN (*Festschrift 84. Versamml. Deut. Naturf. u. Ärzte von der Med. Naturw. Gesell. Münster, 1912, pp. 94-111*).—A review of the work of this author with reference to the decomposition

of fat by *Penicillium glaucum*. The subject is considered under the following headings: The taking up of fatty acids and glycerol by the cells of the fungus; the cleavage of glycerol; the cleavage of fatty acids; assimilability of fatty acids and molecular synthesis; and the changes produced in the constants of fat through the agency of molds.

The tannins, J. DEKKER (*Die Gerbstoffe*. Berlin, 1913, pp. XIII+636, figs. 3).—This is a large botanical-chemical monograph on the tannins. The first part of the book (pp. 1-292) deals with the literature pertaining to the tannins, and tannin substances and their botany, considered from the standpoint of physiology. The occurrence and significance of the tannins, etc., are discussed.

The second part of the book (pp. 295-586) considers the subjects under the following headings: Tannin and the tannoids; substances from which tannins originate; chemical classification, definitions, reactions, and properties; quantitative analysis; and the use of tannins in the arts, sciences, and industries.

Investigations about chlorophyll, R. WILLSTÄTTER and A. STOLL (*Untersuchungen über Chlorophyll*. Berlin, 1913, pp. VIII+424, pls. 11, figs. 16).—This work comprises unpublished investigations which have been conducted during the last years by the authors and deals with methods and results. It discusses the subject under 3 headings, namely, the isolation of chlorophyll, the separation and quantitative determination of all the components of the coloring matter of leaves, and the hydrolysis of chlorophyll. A large bibliography is included.

Principles of ferment methods, J. WOHLGEMUTH (*Grundriss der Fermentmethoden*. Berlin, 1913, pp. IX+355).—A text-book on the subject designed for physicians, chemists, and botanists, and divided into a general and special part. The general part deals with the nature and properties of ferments or enzymes, the general principles involved in enzym investigations, the preparation of solutions of ferments and the isolation of ferments, and a chapter on filtration and dialysis. The special part considers carbohydrate-splitting ferments (ferments cleaving polysaccharids, trisaccharids, disaccharids, and detection of monosaccharid-splitting ferments); fat-splitting ferments (lipases and esterases); protein-splitting ferments; ferments cleaving nuclein and nuclein bases; oxidases; catalase; and coagulation of the blood.

The reversibility of ferment action, E. BOURQUELOT (*Rev. Gén. Sci.*, 24 (1913), No. 18, pp. 687-693, fig. 1).—A discussion of this topic, with special reference to the work of the author and his coworkers. The significance of the reversibility of ferment action for chemistry and physiology is pointed out.

Action of sucrase from koji in the presence of various acids, G. BERTRAND and FRAU ROSENBLATT (*Abs. in Chem. Ztg.*, 37 (1913), No. 36, p. 366).—Sucrase obtained from koji shows its greatest activity in those solutions in which the hydrogen ion concentration of the solution corresponds to the neutral point of helianthin.

Action of hydrogen peroxid upon the amylase of woman's milk, L. LAGANE (*Compt. Rend. Acad. Sci. [Paris]*, 156 (1913), No. 25, pp. 1941-1943).—The addition of hydrogen peroxid in small amounts to raw human milk accelerates the starch liquefying power and to a lesser extent increases the saccharifying power of amylase.

The significance of hydrogen ions for the rennet and acid coagulation of milk, O. ALLEMANN (*Biochem. Ztschr.*, 45 (1912), No. 3-4, pp. 346-358; *abs. in Chem. Ztg.*, 36 (1912), No. 88, p. 841).—The procedure followed was Van Dam's (E. S. R., 20, p. 1178), but as the results obtained with milks having additions of acids were unsatisfactory, it was necessary to add to the milk a reaction regulator which consisted of sodium acetate-acetic acid mixtures of different

hydrogen ion concentration. The time of coagulation was noted in these mixtures, and in this way was shown to be directly proportional to the concentration of the hydrogen ions.

In adding the acetate-acetic acid mixture a zonal change in the milk was noticeable, and simultaneously, a change in the surface tension. Up to a hydrogen ion concentration of 0.56×10^{-5} no change in the mixture was noticeable, but from 0.64×10^{-5} to 1.29×10^{-5} a diffuse clouding was seen, and at 1.29×10^{-5} the casein was precipitated.

From this it was concluded that the coagulation of milk through acid is a function of the actual hydrogen ions. The fact that casein is precipitated from milk at 1.29×10^{-5} led the author to believe that the reason purified casein is only precipitated at 2×10^{-5} is because during the process of purification some changes in its make-up take place.

Two processes, i. e., the forebreak and the separation of the curd, which occur in the manufacture of Emmental cheese, could be explained by some of the findings with the acetate-acetic acid mixture. Both are dependent upon an optimum of hydrogen ion concentration; that for the forebreak is 0.45×10^{-5} , and that for the separation is 1.8×10^{-5} .

The effect of the salts of the rare earths upon the coagulation of milk by rennet, A. FROUIN and V. MERCIER (*Compt. Rend. Soc. Biol. [Paris]*, 74 (1913), No. 17, pp. 990, 991; *abs. in Internat. Inst. Agr. [Rome]*, Mo. Bul. Agr. Intel. and Plant Diseases, 4 (1913), No. 7, p. 1099).—The metals studied were in the form of sulphates of cerium, lanthanum, neodymium, praseodymium, samarium, and thorium. The results showed that coagulation of milk is hastened by the presence of these salts.

Does milk contain phosphatids? V. NJEGOVAN (*Biochem. Ztschr.*, 54 (1913), No. 1-2, pp. 78-82).—In this investigation the sodium sulphate method (E. S. R., 28, p. 610) was used.

As a result the author asks whether we are justified in believing that milk contains phosphatids. The small traces of phosphorus which are obtained by the alcoholic extraction undoubtedly can be attributed to the presence of decomposition products of casein. This is demonstrated by the fact that repeated extraction of casein always yields phosphorus in the extracts.

Casein (Merck) prepared according to Hammarsten's method is slightly soluble in hot absolute alcohol and the alcoholic solution on evaporation yields phosphorus. The small amounts of phosphorus noted in the ether and chloroform extracts are due to the fact that these solutions contain particles of insoluble substances which do not filter out. Sodium sulphate is said not to affect the solubility of phosphatids.

The dominance of Roquefort mold in cheese, C. THOM and J. N. CURRIE (*Jour. Biol. Chem.*, 15 (1913), No. 2, pp. 249-258, figs. 2).—The purpose of this investigation was to obtain information relating to the gases within Roquefort cheese and their relation to the growth of *Penicillium roqueforti*.

An "analysis of the gas collected from the air spaces in Roquefort cheese (both imported and made experimentally) shows that the percentage of free oxygen is low, in no case among those tabulated rising above 7 per cent. Carbon dioxide appears in proportions ranging from 21 to 40 per cent. The percentage of carbon dioxide is highest in comparatively fresh-made cheese, where it arises both from respiration of the micro-organisms present and as a by-product of the decomposition of lactose by bacteria. From the maximum figure the percentage falls slowly by diffusion. No hydrocarbons were found. Hydrogen, if present, was in very small amount.

"Cultures of 22 species of *Penicillium* and 5 species of *Aspergillus* grown in a Novy culture jar for 19 days produced an atmosphere containing approxi-

mately 25 per cent of carbon dioxid. Cultures of the same species in the same jar with an initial mixture of air and 25 per cent of carbon dioxid showed 37 per cent of carbon dioxid at the end of 8 days, with marked reduction in the activity of certain species. Cultures of the same series of fungi in jars with approximately 50 per cent of carbon dioxid in the initial mixture left the mixture approximately unchanged at the end of 7 days. Fungus growth was stopped for certain species, greatly reduced for all, but 6 of the species tested produced very considerable growth.

"Cultures of this series of species grown for 8 days in jars with 75 per cent of carbon dioxid in the initial mixture showed that *P. roqueforti* alone was able to produce fairly strong colonies in this mixture. A mixture of 75 per cent of carbon dioxid with air gives approximately 5 per cent of free oxygen. The close correspondence between the results of gas analysis and comparative culture indicates that the low percentage of oxygen in the open spaces within the cheese accounts for the dominant activity of *P. roqueforti* in Roquefort and related types of cheese."

Report of the progress made in the field of milk chemistry and dairying during the second half of 1912, W. GRIMMER (*Milchw. Zentbl.*, 42 (1913), Nos. 5, pp. 139-144; 6, pp. 178-185).—This deals with the literature on milk production, milks of various kinds, milk constituents, changes in milk and its constituents, bacteria in milk, milk enzymes, immune bodies and milk as an antigen, rennet and coagulation by rennet, milk as a food, milk products, dairy machinery, milk supply, and methods for examining milk.

The chemistry of rubber, B. D. PORRITT (*London*, 1913, pp. VII+96).—This monograph is said to be a concise presentation of the chemistry of rubber. Its contents are as follows: The properties of crude rubber; constitution and derivatives; methods of vulcanization; theories of vulcanization; waste rubber and its utilization; and synthetic caoutchouc. A bibliography of 179 titles is appended.

About the use of red cabbage extract as an indicator for the colorimetric measurement of the hydrogen ion concentration, L. E. WALBUM (*Biochem. Ztschr.*, 48 (1913), No. 4, pp. 291-296; *Compt. Rend. Lab. Carlsberg*, 10 (1913), No. 2, pp. 227-232).—The red coloring matter of red cabbage was found to serve well as an indicator for measuring the hydrogen ion concentration, and the figures obtained agreed fairly well with those given by the electrometric method. The indicator worked well in the presence of an appreciable amount of proteins. Neutral salts (up to $\frac{1}{2}$ molecule of sodium chlorid), toluene, and chloroform did not affect the results of the measurements.

The separation of δ -alanin and δ -valin, P. A. LEVENE and D. D. VAN SLYKE (*Jour. Biol. Chem.*, 16 (1913), No. 1, pp. 103-120).—" δ -Alanin combines with phosphotungstic acid in the ratio of approximately 1:14 by weight, forming a crystalline salt. At 0°, in a solution containing, per 100 cc., 20 gm. or more of phosphotungstic acid in excess of the amount combining with the alanin, and 10 gm. of sulphuric acid, the solubility of alanin is only 0.15 gm. per 100 cc. The solubility of δ -valin under the same conditions is 1.21 gm. per 100 cc. By alternate crystallization of valin as the free amino acid and of alanin as the phosphotungstate, one can effect a practically quantitative separation of a mixture of the 2 amino acids."

Examination of hydrocarbon oils and fats, D. HOLDE (*Untersuchung der Kohlenwasserstofföle und Fette sowie der ihnen verwandten Stoffe*. Berlin, 1913, 4. ed., rev. and enl., pp. XVI+596, pls. 2, figs. 115).—This edition includes the examination of vegetable and animal fats and oils. In addition it takes up some of the commodities which are made from fats and oils such as candles,

hardened oils, soaps, soap powder, glycerin, wool oils, turkey-red oil, linseed-oil varnishes, oil colors, linoleum, etc.

New viewpoints for the analysis of oils and fats, A. BÖMER (*Festschrift 84. Versamml. Deut. Naturf. u. Ärzte von der Med. Naturw. Gesell. Münster, 1912*, pp. 87-93).—This discusses the value of the different criterions which have been utilized for the judgment of fats and oils. The influence on the composition of the body and milk fats of feeding certain substances, and the determination of various specific fats in admixture with other fats, are also considered.

Yearly report in regard to the progress made in the examination of foods and condiments, H. BECKURTS, H. FRERICHs, and R. BOHLMANN (*Jahresber. Untersuch. Nahr. u. Genussmtl.*, 22 (1912), pp. 176).—This report, which constitutes a review of the literature appearing during the year 1912 on food and condiment chemistry, is divided into a general and special part and an appendix dealing with toxicological chemistry. For the previous report see another note (E. S. R., 29, p. 506).

The differentiation by biological means of Indian buffalo meat and beef, F. SCHADAUER (*Ztschr. Fleisch u. Milchw. Hyg.*, 23 (1913), Nos. 18, pp. 409-416; 19, pp. 437-442).—According to the author's investigations, it is possible to distinguish between the two sorts of meat by means of the precipitin reaction.

A rapid and easy formula for calculating the fat-free dry substance in milk, H. M. HÖYBERG (*Ztschr. Fleisch u. Milchw. Hyg.*, 23 (1913), No. 23, pp. 539-541).—Fleischmann's formula is considered cumbersome and Ackermann's calculator is tiresome to the eye. The author proposes the following formula for this

purpose: Fat-free solids = $\frac{v+f}{4}$, v representing the specific gravity minus 1, multiplied by 1,000, and f the percentage of fat contained in the milk; e. g., in a milk having a specific gravity of 1.034 and containing 2.8 per cent of fat $\frac{34+2.8=}{4}$ 9.2 per cent.

The formula was tried with 24 samples of suspicious milks and 20 samples of normal milk and apparently gave good results.

Estimation of lactose in milk, R. SANFELICI (*Staz. Sper. Agr. Ital.*, 45 (1912), No. 12, pp. 908-916).—In a comparative study between Fehling's and Pavy's methods for determining lactose in milk serum, the figures obtained with the Pavy method were from 0.2 to 0.25 per cent the higher. The Pavy method has several advantages over the Fehling method and is deemed sufficiently exact for estimating lactose in milk.

Determination of fat in dried milk, RUSCHE (*Molk. Ztg. [Hildesheim]*, 27 (1913), No. 50, pp. 977, 978).—Milk powders made by the Hatmaker process when fresh gave good results with the Teichert, Hesse, Siegfeld, Burr, and other methods, but with old powders the figures obtained were inaccurate. Therefore the necessity for a method for this class of goods became apparent and the following was devised:

In the usual Gerber butyrometer place in layers 10 cc. of sulphuric acid (specific gravity 1.82), 5 cc. of water, and 1 cc. of alcohol; then weigh off 1.133 gm. of milk powder in a specially devised weighing funnel provided with rubber stoppers, add powder to the mixture in the butyrometer, and finally add 5 cc. of water. After shaking thoroughly place the butyrometer in a water bath having a temperature of from 65 to 70° C., then shake here and there until the solution has become clear; centrifuge the butyrometer with its contents for 15 minutes, place it in the water bath again, and read off the height of the fat column. The results multiplied by 10 give the percentage of fat in the milk powder.

The figures obtained by the method are deemed satisfactory and no plug formation or similar condition takes place.

A handbook of sugar analysis, C. A. BROWNE (*New York and London, 1912, pp. XI+787+[280], figs. 200*).—This is a practical and descriptive treatise on the subject of sugar analysis and is meant for use in research, technical, and control laboratories. The contents of part 1, which deals with physical and chemical methods of sugar analysis, are as follows: Sampling of sugar and sugar products; densimetric methods of analysis; principle and uses of the refractometer; polarized light, theory, and description of polarimeters; theory and description of saccharimeters; polariscope accessories; specific rotation of sugars; methods of simple and of invert or double polarization; special methods of saccharimetry; miscellaneous physical methods as applied to the examination of sugars; qualitative methods for the identification of sugars; reduction methods for determining sugars; special quantitative methods; and combined methods and the analysis of sugar mixtures.

The contents of part 2, which deals with the occurrence, methods of preparation, properties, and principal reactions of the sugars and allied derivatives are as follows: Classification of the sugars and their formation in nature; the monosaccharids; the disaccharids; the trisaccharids and tetrasaccharids; the amino sugars and the cyclases; and the sugar tables are appended.

A number of sugar tables are appended.

Quantitative determination of reducing sugars by Lehmann's method, L. GRIMBERT (*Bul. Soc. Chim. France, 4. ser., 18 (1913), No. 3, pp. 117-120; noted in Chem. Ztg., 37 (1913), No. 33, p. 334*).—The author states that excellent results may be obtained if a sufficient amount, but not an excess, of dilute acid is used in the method, and if the liberated iodine is titrated indirectly by adding an excess of sodium hyposulphate and then titrating back with iodine.

The estimation of methyl alcohol in spirits, etc., J. HETPER (*Ztschr. Untersuch. Nahr. u. Genussmit., 24 (1912), No. 12, pp. 731-737; abs. in Chem. Ztg., 37 (1913), No. 35, Repert., p. 163*).—In this method it is first necessary to take the specific gravity of the distillate obtained from the solutions made acid and alkaline in order to determine their total alcohol content. With an alcohol content of 45 to 55 per cent by weight, according to the table which accompanies the article, the specific gravity of ethyl and methyl alcohol shows very little difference. The distillate is then diluted to from 0.91 to 0.915, and a definite amount of potassium permanganate solution containing phosphoric acid is added whereby the methyl alcohol is converted into carbon dioxide and the ethyl alcohol is oxidized into acetic acid. One gm. of methyl alcohol requires 187.5 cc. of normal potassium permanganate solution and ethyl alcohol only 87 cc.

The other volatile substances present in spirituous liquors, with the exception of furfural and ethyl ether, have no marked effect upon the results.

About the analytical estimation and technical preparation of cellulose, J. KÖNIG (*Festschrift 84. Versamml. Deut. Naturf. u. Ärzte von der Med. Naturw. Gesell. Münster, 1912, pp. 78-86*).—This article deals with the various kinds of cellulose, the different methods for determining cellulose, the factors which interfere with the results obtained in the analyses, and the present-day methods for obtaining pure cellulose from different sources. In addition to this the use of cellulose as a feeding stuff, for paper making, and for alcohol manufacture is considered.

Estimation of cellulose in woods and textile fibers, J. KÖNIG and F. HÜHN (*Ztschr. Farb. Indus., 11 (1912), No. 14, pp. 209-211; abs. in Chem. Zentbl., 1912, II, No. 12, pp. 1066, 1067; Analyst, 37 (1912), No. 440, pp. 510, 511*).—This is a reply to the abstract previously noted (E. S. R., 28, p. 805), in which it is maintained that Cross and Bevan have not shown conclusively that

chlorination is unaccompanied by oxidation. Furfural-yielding groups are synonymous with pentosans, according to Tollens, and these groups must first be removed by drastic hydrolysis before the cellulose can be considered pure.

"The maximum specific rotation of solutions of cellulose in acid zinc chlorid was not put forward as a test for pure cellulose, but the fact was merely recorded that the solutions which showed the maximum rotations were derived from celluloses which, by other characters, were proved to be the purest. [The authors] found by their proposed method, in a sample of commercial sulphite wood cellulose, only 32.21 per cent of 'true cellulose;' this result is upheld against the criticism of Cross and Bevan on the ground that the sample still contained much lignin. The differences between the authors and Cross and Bevan turn on the question of a definition of chemically pure cellulose, as contrasted with the technically pure article. König and Braun, by the isolation of lignin, free from accompanying cellulose, but still retaining the structural form of the cell membrane, have proved that the lignocellulose of wood is not a chemical combination, but a mixture of two mutually interpenetrating colloids."

Home manufacture of cider vinegar, L. L. VAN SLYKE (*Better Fruit*, 7 (1913), No. 11, pp. 7-10).—Previously noted from another source (E. S. R., 22, p. 416).

Grape juice, F. T. BIOLETTI (*California Sta. Circ.* 108, pp. 12, fig. 1).—This is a short account of methods for preparing and preserving unfermented grape juice, with "enough detail to enable anybody to devise means to conserve small quantities for domestic use, or to judge of the efficacy of industrial methods or installations."

The varieties of grapes deemed best suited for making grape juice are those which show a high acidity when ripe, although any grape making a good wine will make a good grape juice. The best grape juice is made from mature grapes in perfect condition, but with the proper methods of handling table-grape culls may be used for this purpose. When grapes low in acidity are to be employed, especially those which are very sweet, a little citric acid may be added to the juice, or it may be blended with that of acid varieties.

Typical analyses of some Californian grapes considered suitable for grape juice are reported in tabular form. The best stage to gather Muscat grapes was when the sugar had risen to 25.5° Balling. "As a general rule, the grapes for flavoring should be gathered when the sugar reaches 23 to 25° and the grapes for acidity when it reaches 19 to 21°."

Utilization of juice from waste oranges, W. V. CRUESS (*Cal. Cult.*, 41 (1913), No. 13, pp. 304, 305, 323, figs. 2).—This article gives directions for making unfermented orange juice from frozen or cull oranges. From 100 parts of sound cull oranges 23.1 parts of juice were obtained, or 55.4 gal. of juice per ton of fruit. Frozen oranges yielded from 42.5 to 45 gal. per ton of fruit.

The methods of crushing and pressing the oranges and defecating, filtering, pasteurizing, storing, and bottling the juice are described. The filtering apparatus and a homemade pasteurizer are illustrated.

Formulas for preserving and processing fruits, vegetables, etc., for exhibition purposes, J. H. PAGE (*Bur. Mines, Manfrs. and Agr.* [Ark. Pub.], 1913, pp. 11).—Directions and formulas are given.

Bacon curing on the farm, J. C. NEWSHAM (*Jour. Bd. Agr.* [London], 20 (1913), No. 6, pp. 478-487).—A detailed description of the cottager methods of curing bacons and hams in vogue in the British Isles, including the Hampshire, Yorkshire, Buckinghamshire, Cumberland, Scotch, and Irish methods and recipes for curing.

Industrial utilization of zein, the protein of maize, J. J. GEISTDORFER (*French Patent* 446,840, Aug. 2, 1912; *abs. in Chem. Ztg.*, 37 (1913), No. 35,

Report., p. 168).—Zein is proposed as an electrical insulating material and for the impregnation of paper for the manufacture of isolating sheets. When mixed with kaolin and sulphur it yields a plastic substance which can be pressed hydraulically.

Proceedings of the twenty-ninth annual convention of the Association of Official Agricultural Chemists, edited by W. D. BIGELOW and G. O. SAVAGE (*U. S. Dept. Agr., Bur. Chem. Bul.* 162, pp. 232, pls. 2).—This is the official report of these proceedings, which have been previously noted (*E. S. R.*, 27, p. 495).

METEOROLOGY—WATER.

Agricultural zones of the Tropics in their relation to climate.—I. America, R. HENNIG (*Tropenpflanzer, Beihefte*, 14 (1913), No. 4, pp. 247-438).—The climatic conditions of the tropical portions of Florida and the Gold Coast, Mexico, Central America, West Indies, and South America are described, and the relation of natural vegetation, cultivated plants, domestic animals, and races of men to those climatic conditions are discussed in detail. An extensive bibliography of the subject is given.

Bulletin of the Mount Weather Observatory (*U. S. Dept. Agr., Bul. Mount Weather Observ.*, 6 (1913), pt. 2, pp. 35-60, figs. 14).—This number contains the following articles: Vertical Temperature Gradients Between Mount Weather, Va., and Valley Stations, by A. J. Henry; A Change in Skylight Polarization, by H. H. Kimball; and Free Air Data at Mount Weather, Va., for January, February, and March, 1913 (illus.), by W. R. Blair.

Meteorological observations at the Massachusetts Agricultural Experiment Station, J. E. OSTRANDER and E. K. DEXTER (*Massachusetts Sta. Met. Buls.* 299, 300, pp. 4 each).—Summaries of observations on pressure, temperature, humidity, precipitation, wind, sunshine, cloudiness, and casual phenomena during November and December, 1913, are presented. The general character of the weather for November is briefly discussed, and the December bulletin gives a summary for the year. The principal data in this summary are as follows:

Pressure, reduced to freezing and sea level (inches).—Maximum, 30.88, March 18; minimum, 28.55, January 3; mean, 30.037. *Air temperature*, in ground shelter (degrees F.).—Maximum, 100, July 1; minimum, -4.5, February 10; mean hourly, 49.3. *Humidity*.—mean dew-point, 40.1; mean relative humidity, 75.7. *Precipitation*.—Total rainfall or melted snow, 39.5 in.; number of days on which 0.01 in. or more rain or melted snow fell, 135; total snowfall, 26.5 in. *Weather*.—Total cloudiness recorded by sun thermometer, 2,031 hours, or 46 per cent; number of clear days, 105. *Bright sunshine*.—Number of hours recorded, 2,423, or 54 per cent. *Wind*.—Prevailing direction, west; total movement, 55,120 miles; maximum daily movement, 642 miles, January 4; minimum daily movement, 9 miles, September 5; maximum pressure per square foot, 27 lbs., July 23, south-southwest. *Dates of frost*.—Last, May 15; first, September 10. *Dates of snow*.—Last, April 9; first, October 31.

Weather report, W. H. DAY (*Ann. Rpt. Ontario Agr. Col. and Expt. Farm*, 38 (1912), pp. 34-40).—Summaries by months of observations during 1912 at Guelph and other places in Ontario on temperature, rainfall, snowfall, wind, and length of season are given.

A provisional statement regarding the total amount of evaporation by months at 23 stations in the United States, 1909-10, F. H. BIGELOW (*U. S. Dept. Agr., Weather Bur. Abstract of Data* 4, pp. 6).—This statement was compiled from observations by the U. S. Weather Bureau, Reclamation Service, and Geological Survey. The observations were made at Salton Sea, Indio, Mecca, Brawley, Lake Tahoe, and Mammoth, Cal.; North Yakima and Lake

Kachess, Wash.; Hermiston and Ady, Oreg.; Granite Reef Dam, Ariz.; California, Ohio; Birmingham, Ala.; Dutch Flats, Nebr.; Minidoka Dam and Deer Flat, Idaho; Fallon, Nev.; and Elephant Butte, Carlsbad, and Lake Avalon, N. Mex. The observations were made on the ground and at different heights above the ground (2, 10, and 20 ft.).

The annual precipitation of the United States for the years 1872 to 1907, F. H. BIGELOW (*U. S. Dept. Agr., Weather Bur. Abstract of Data 3, pp. 17, figs. 8*).—The annual precipitation at selected stations in seven districts of the United States is shown in tables and charts. The mean annual precipitations as deduced from data are as follows: North Pacific States and northern Rocky Mountain plateau, 23.89 in.; northern Rocky Mountain slope, 19.11 in.; Lake region and central valleys, 35.55 in.; North Atlantic States and New England, 40.61 in.; east Gulf States, 50.04 in.; west Gulf States and southern Rocky Mountain slope, 23.50 in.; and southern Pacific States and southern Rocky Mountain Plateau, 14.55 in.

Precipitation in western Kansas, P. C. DAY (*U. S. Dept. Agr., Weather Bur. Abstract of Data 2, pp. 6, pl. 1*).—Data reported show that "from Lawrence, in the extreme eastern portion, the annual precipitation—36.29 in.—diminishes to 31.43 at Manhattan, to 28.84 at Salina, to 23.48 at Hays, to 20.84 at Gove, and to 16.88 in. at Wallace, in the extreme western part of the State. The total decrease in the annual precipitation from the eastern to the western part of the State is slightly more than 20 in., or about 5 in. for each 100 miles westward. . . .

"Considering the amounts received during the growing season, April to September, inclusive, as compared with the amounts for the same months at Lawrence, the rate of decrease westward is considerably less. Starting with Lawrence, 25.18 in. during the crop-growing season, Manhattan has 23.54 in., or 93 per cent; Salina 21.90, or 87 per cent; Hays 17.89, or 71 per cent; Gove 16.28, or 65 per cent; and Wallace 13.83 in., or 55 per cent of that received at Lawrence.

"The distribution north and south over the State is very nearly uniform, except there appears a slight excess in the norwestern part of the State."

Precipitation in the Panhandle region of Texas, F. H. BIGELOW (*U. S. Dept. Agr., Weather Bur. Abstract of Data 1, pp. 2*).—The average annual rainfall for 28½ years (1880–1908) at Amarillo and Fort Elliott is shown to be 22.39 in.

[Rainfall and flow of streams in Massachusetts in 1912] (*Ann. Rpt. Bd. Health Mass., 44 (1912), pp. 255–271, figs. 7*).—The average rainfall for the year was 39.48 in., as compared with a normal of 44.78 in. There was an excess of rainfall during March, April, May, and December and a deficiency during the rest of the year. The monthly flow during 1912, as compared with previous years and with normal, is reported for the Sudbury, Nashua, and Merrimack rivers. A summary table also shows the weekly fluctuations in flow of these rivers.

The effects of ice on stream flow, W. G. HOYT (*U. S. Geol. Survey, Water-Supply Paper 337, 1913, pp. 77, pls. 7, figs. 18*).—This paper presents the available information on the subject of winter flow, discussing the factors that influence the run-off during the periods of low temperature, the varieties of ice and their effect on the applicability of the laws of open-channel flow, and the collection and interpretation of necessary data.

Report of committee on water supplies (*Amer. Jour. Pub. Health, 3 (1913), No. 12, pp. 1326–1337*).—This report discusses six features of water supply development as follows: Hygienic aspects, rate of installation of filters, sterilization, decolorization with an overdose of coagulant, decolorization as an adjunct of softening, and corrosion of metals.

The hypochlorite treatment is considered principally applicable "for emergency use or as a finishing process after filtration," but "must not be considered as a substitute for other established means of water purification."

Ozone treatment is condemned as expensive and difficult to apply thoroughly. "Somewhat the same remarks may be made about the use of violet rays for the sterilization of water. . . . Its use has been advocated and its success, on a laboratory scale, has been well demonstrated, but its excessive cost, its complicated nature, and the difficulty of making it applicable to the treatment of large volumes of water, together with the other general limitations already referred to, do not at present promise well for its commercial success."

Studies of fish life and water pollution, H. W. CLARK and G. O. ADAMS (*Ann. Rpt. Bd. Health Mass., 44 (1912), pp. 336-345*).—A report of these studies has been noted from another source (*E. S. R., 29, p. 315*).

Relation of purity of water supply to typhoid fever, J. W. ELLMS (*Amer. Jour. Pub. Health, 3 (1913), No. 12, pp. 1290, 1291*).—It is stated that in the three years since the introduction of a purified water supply the typhoid death rate of Cincinnati has decreased nearly 80 per cent.

The prevention of typhoid fever in the rural districts of Virginia, A. W. FREEMAN (*Amer. Jour. Pub. Health, 3 (1913), No. 12, pp. 1322-1325*).—The campaign of education of the state health department, emphasizing especially the importance of sanitary privies, suppression of flies, and bedside prophylaxis, is described.

In this campaign special emphasis is not laid upon the water supply because "typhoid fever of the rural districts of Virginia is largely a matter of the summer months," and in these "months the influence of water in the transmission of the disease is not apparently of great importance. . . . The recognition of human filth as the source of the infection, and the avoidance of all fecal contamination, whether by flies, food, clothing, hands, water, or any other means whatever, constitutes the one and only precaution necessary for the absolute prevention of the disease."

The results of the state campaign have been evident. "The interest of the people at large in the prevention of typhoid has been greatly increased and their knowledge of the means necessary to this end enlarged. Bedside prophylaxis has undoubtedly been wonderfully improved. The campaign for the sanitary privy has begun slowly to show results in the building and use of the types recommended by the department. Most important of all, the number of cases, reported and estimated, has shown steady and decisive decline."

SOILS—FERTILIZERS.

A descriptive catalogue of the soils of Virginia so far identified in the soil survey (*U. S. Dept. Agr. Bul. 46, pp. 21, figs. 7*).—The soils of Virginia are classified under 5 soil provinces, which are (1) Piedmont Plateau Province, containing 9,501,600 acres; (2) Appalachian Mountain and Plateau Province, containing 6,420,000 acres; (3) Coastal Plains Province, containing 5,136,000 acres; (4) Limestone Valley and Upland Province, containing 3,081,600 acres; (5) River Flood Plains Province, containing 1,540,800 acres. In province No. 1 the Cecil series ranging in texture from sand to clay is most widely distributed and important, with the Louisa, Chester, and Iredell series, second, third, and fourth, respectively. In province No. 2 the De Kalb series is most widely distributed but has little agricultural value. The Porters series is second in extent and has only average agricultural value, being better adapted to forestry. In province No. 3 the Norfolk series predominates. About 10 per cent of these soils

constitute an important part of the great truck soils of the coast, while the remaining 90 per cent is lying idle or is used for general farming to which they are not adapted. The Portsmouth series in this province is second in extent and if well drained is adapted to truck and garden crops. In province No. 4 the Hagerstown series predominates and is well suited to cultivation. In province No. 5 meadow and swamp soils largely predominate. The cultivated soils are chiefly of the Wickham and Congaree series, both having relatively high agricultural values.

Soil building for South Carolina, W. H. BARTON (*South Carolina Sta. Circ.* 13, pp. 8).—This circular presents by diagram the logical order of practice considered necessary for the enrichment of the soils of the State, briefly indicates some of the results of such practice, outlines methods of procedure, and suggests a plan of cooperation between agricultural and country school education.

The formation of laterite in the soils of southern Italy, L. BERNARDINI and G. MAZZONE (*Staz. Spcr. Agr. Ital.*, 46 (1913), No. 2, pp. 146-156; *abs. in Chem. Zentbl.*, 1913, I, No. 18, p. 1624; *Chem. Abs.*, 7 (1913), No. 19, p. 3381).—To determine the extent to which laterite formation had gone on, 5 gm. of the fine soil was first boiled for $\frac{1}{4}$ hour in 80 cc. of hydrochloric acid (specific gravity 1.2). The acid was decanted and the process repeated for $\frac{1}{4}$ hour with fresh acid, then after a second decantation again repeated for $\frac{1}{2}$ hour. The insoluble residue was neutralized, further digested at from 50 to 60° C. for 5 minutes with a solution of sodium hydroxid (specific gravity 1.04), and the silica and alumina determined in the combined acid and alkali extracts. The insoluble residue from this treatment was evaporated to dryness with from 10 to 20 cc. of concentrated sulphuric acid, neutralized with sodium hydroxid, digested for 20 minutes at from 50 to 60° with 80 cc. of sodium hydroxid (specific gravity 1.06) and the silica and alumina determined in the solutions.

If the first treatment (with hydrochloric acid and sodium hydroxid) showed three or more parts of silica to one of alumina this was taken to indicate ordinary clay decomposition. If, however, the ratio was appreciably less than 3:1 and at the same time the ratio obtained by the second treatment (with sulphuric acid and alkali) was over 3:1, laterite formation was indicated.

The results of these tests showed that laterite formations predominated in southern Italy in contrast to the soils of middle Italy.

Report on soil studies in Bessarabia, A. J. NABOKICH (*Internat. Mitt. Bodenk.*, 3 (1913), No. 4, pp. 338-352, pl. 1).—This report describes the geology, climate, and geography of the region in their relations to soil formation and composition.

The geological formations are said to be largely the results of ancient erosions. Chernozem soils rich in carbonates, sodium salts, and gypsum predominate, and some also contain considerable phosphoric acid. As the alkalis are found mainly in the lower strata of these soils, it is concluded that they were formed by the climate of a preceding age.

The main chernozem zone soil is said to contain from 5 to 10 per cent humus, that of the southern border from 3 to 5 per cent, and that of the coast from 2 to 3 per cent.

Podzol soils containing from 2 to 3 per cent humus, extend the length of the Austrian border, while next to them lie alternating strips of degraded and normal chernozem soils. The chernozem soils are in many places covered with sand or sandy soils, especially in the center of the main zone.

Deli soils, J. G. C. VRIENS (*Meded. Deli-Proefstat. Medan*, 7 (1912), No. 6, pp. 297-308).—Tables of chemical, physical, and mechanical analyses of a number of soils are given.

The relation between soil, vegetation, and climate on the islands of East Friesland, F. SCHUCHT (*Internat. Mitt. Bodenk.*, 2 (1912), No. 6, pp. 485-532, pls. 3, figs. 21).—Descriptions are given of the soil, vegetation, and climate of these islands.

The soils are chiefly sand or very sandy clays, very fine grained, with a lime content varying within wide limits. The soil areas are divided into sandy coast plains, sand dunes, and sand marshes. The sandy plain soils contain much lime, chiefly originating from seashells, the newer dunes somewhat less lime, and the old dunes relatively little. Humus is found only in the very old dunes and in the valley dunes and is seldom over one per cent. These soils are very poor in plant food. The sand marshes with a slime covering support a heavy vegetation compared with that of the dunes, and are relatively rich in plant food, especially lime and humus.

The salt content of the ground water and of the soils, which is said to come from sea water, exercises a marked influence on the kind and amount of the vegetation of the islands.

The climate is oceanic, being characterized by a constant temperature, gradual changes from warm to cool and vice versa, high content in the air of moisture, ozone, and salt, uninterrupted air movement, and much sunshine.

Demonstration of the law of minimum, S. GOY (*Mitt. Deut. Landw. Gesell.*, 28 (1913), No. 45, p. 623, fig. 1).—A diagram is given illustrating the law of minimum as applied to growth factors in a soil.

Evaporation of water from soils, C. B. LIPMAN (*Cal. Country Jour.*, 29 (1913), Nos. 35, pp. 1, 14; 37, pp. 1, 2; 39, pp. 1, 2).—This is a popular discussion of evaporation of water from soils in which the work of numerous investigators is briefly reviewed. The effect of soil texture, surface cultivation, and moisture in the air on evaporation from bare soils is pointed out, and means for preventing evaporation are suggested, such as shading, windbreaks, and protective coverings, including straw, manure, and soil or dust mulches. Attention is called especially to the enormous evaporation of water through plant transpiration.

The presence of arsenic as a normal element of soil, G. ZUCCÀRI (*Gaz. Chim. Ital.*, 43 (1913), II, No. 4, pp. 398-403).—Analyses of 20 soil samples, varying in physical and chemical composition and taken from different depths in different geological formations and at varying elevations, showed an arsenic content varying from 0.187 to 6 parts per 100,000 of soil, being largest in soils containing the most iron compounds, and varying almost directly with the iron content. This is ascribed to the greater tendency of arsenic to combine with iron than with other metals. It is thought that alumina and the carbonates of lime and magnesia may have a minor fixing action on the arsenic. Humus, which was present in abundance in the samples, did not tend to prevent the detection of the arsenic.

Selective adsorption by soils, E. G. PARKER (*Jour. Agr. Research*, 1 (1913), No. 3, pp. 179-188, figs. 2).—Various theoretical considerations bearing on the adsorptive power of soils are discussed, and several series of experiments in which samples of soil were shaken with solutions of potassium chlorid alone and with sodium nitrate, monocalcium phosphate, and other salts and the amount of the adsorbed bases determined by analysis of the resultant solution are reported.

These experiments were based "on the assumption that certain ingredients of the soil adsorb in part the base of a neutral salt in solution and that the free acid resulting from the hydrolysis caused by this adsorption reacts with certain of the soil particles and dissolves an almost equivalent amount of bases of the soil."

Summarizing the results, the author states that "soils not only have the power of adsorbing dissolved salts from solutions, but also of adsorbing one ion at a greater rate than the other, or selectively adsorbing, to a marked extent.

"The presence of bases of the soil (Ca, Mg, etc.) in solution after shaking certain salt solutions with or percolating through a soil is probably not due to a direct chemical reaction of the salt in solution with the silicates of the soil, but to a reaction of free acid, resulting from a selective adsorption of the cation with the mineral components of the soil.

"The rate of adsorption of chlorin ions from solution by soils is much less than of potassium ions. The selective adsorption of potassium from a potassium-chlorid solution by a soil increases in amount with the concentration up to a certain point and then remains practically constant. The percentage of potassium adsorbed from a potassium-chlorid solution increases asymptotically as the concentration of potassium chlorid decreases and at very low concentrations adsorption is practically complete. In general, the smaller the soil particles the greater the selective adsorption of potassium from a potassium-chlorid solution by the soil.

"The presence of sodium nitrate decreases the adsorption of potassium from a solution of potassium chlorid by a soil up to a concentration of about 37.5 gm. of potassium chlorid per liter and then increases it. The presence of monobasic calcium phosphate does not change appreciably the adsorption of potassium from a potassium-chlorid solution by a soil.

"Finally, if a mineral fertilizer be applied to a soil and exposed to the rain and thus dissolved and carried through the soil in solution, these substances will be adsorbed (an entirely physical phenomenon) either as a whole or selectively from the solution by the vast surface of the soil particles and will be held there by this same physical force until the plant or subsequent leaching removes it. The presence of other mineral substances added to the soil may or may not increase or decrease the rate at which this adsorptive phenomenon takes place."

The inactivity of the soil protozoa, R. GREIG-SMITH (*Proc. Linn. Soc. N. S. Wales*, 37 (1912), pt. 4, pp. 655-672, figs. 7; *abs. in Centbl. Bakt. [etc.]*, 2. Abt., 39 (1913), No. 4-7, p. 152).—In these investigations, continuing previous work (E. S. R., 28, p. 623), the author endeavored to test the action of the soil phagocytes (1) by adding them purposely to soil, and (2) by using the extracts of raw soil, as was done by Russell and Hutchinson, taking care to use soil that had not been overheated and to have controls of unfiltered soil extracts to compare with the filtered, presumably protozoa-free, extracts.

It is concluded from the experiments as a whole "that Russell's contention can not be sustained; the protozoa have little or no action in limiting the number of soil bacteria."

It was found that the larger ciliates, such as *Colpoda cucullus*, were not destroyed when comparatively large amounts of volatile disinfectant were added to the soil. "Upon adding suspensions of protozoa, there was no evidence of any limitation in the numbers of the soil bacteria. Any enhanced effect was due to the addition of the bacteria contained in the suspensions. The filtration of a soil extract had no influence, beyond that of removing some of the bacteria in the suspension. Any phagocytic tendencies that the soil protozoa possess have no influence in limiting the numbers of bacteria in the soil. So far as the growth of bacteria is concerned, the effect of heat is of a different character from that of a volatile disinfectant. Inferentially, the toxins and nutrients of the soil are alone concerned with the changes that occur when soils are heated or treated with volatile disinfectants."

Edaphon, R. H. FRANCÉ (*Das Edaphon. Munich, 1913, pp. 99, figs. 35*).—Edaphon, in contrast to plankton, is here understood to be the plant and animal organisms of the soil. The author deals in some detail with the conditions of soil favorable to the life and activity of these organisms, giving a systematic classification and discussion of 120 different organisms and the results and conclusions of a general ecological investigation of the types.

Light was found to influence more or less the distribution of the organisms near the surface and in the soil depths. The edaphon was found to reach the minimum number and distribution in the winter, due to frosts, and the maximum in the spring and fall. Increasing soil moisture was ordinarily found to increase the number and distribution. In most of middle Europe no difference was observed in the edaphic development of soils under like ecological conditions, but ordinarily the number of organisms varied with increasing elevation according to their kind within well defined limits, and independently of the variations caused by other local conditions. The number and distribution was also found to be closely related to the geology of a locality and to the petrographic conditions of the substrata. The edaphon in humus-poor soils showed silica-loving characteristics and many of the organisms were found to exist in entirely humus-free soils. On the other hand, the presence of considerable humus was extremely favorable to their growth. It is concluded that the edaphic organisms are active in the formation of humus, in the development of organic matter in new soils, and also in the weathering of rocks.

In examinations of neutral and acid forest soils many more edaphic organisms were found in the former than in the latter, the most of which were *Difflugia* and relatively large forms. Further investigations led to the conclusion that the *Cladosporium* which were present in large numbers have no fixed influence on the number and distribution of the remaining edaphic organisms.

The siliceous algae were found to predominate the year round in cultivated soil and the rhizopods, nematodes, and *Cladosporium* in the forest soils. The large numbers of rhizopods in forest soils are concluded to be due not only to the greater water content but also to the greater humus content and to the chemical influence of amphibious vegetation. Amphibious vegetation influenced the numbers of soil organisms through its influence on humus, but the edaphic development of the soil was found to increase with the factors which make the soil hygrophytic. Fertilization was most favorable to the growth and increase of the edaphon. A discussion of symbiotic relations leads to the conclusion that the edaphon have symbiotic relations similar to those of plankton. In general it is concluded that the edaphic organisms are indispensable as decomposers of organic matter and as soil ventilators for the metabolism of productive soils, and that their method of multiplying is such as to aid the soil ferments and increase its productiveness.

Studies on nitrogen assimilation by free living organisms, H. B. HUTCHINSON (*Rpt. Brit. Assoc. Adv. Sci., 1912, pp. 740, 741*).—Spring applications of carbohydrates to field soil were followed by decreased crop yields, while autumn applications resulted in a decided increase of yield, due, it is thought, to stimulation of nitrogen assimilation by such organisms as *Azotobacter chroococcum*.

"Pot and laboratory experiments show that when plant residues are added to soil or sand a vigorous decomposition of the cellulose by aerobic organisms ensues, and appreciable quantities of nitrogen are assimilated from the atmosphere."

Some effects of humates on plant growth, W. B. BOTTOMLEY (*Rpt. Brit. Assoc. Adv. Sci., 1912, p. 680*).—The author found that peat moss litter is

entirely unsuited for the growth of plants because of its acid reaction and lack of soluble humates. When the peat was subjected to the action of certain micro-organisms a large quantity of soluble humates was formed and the peat was rendered alkaline. A water extract of peat thus treated was found to be capable of supplying all the necessary plant food for successful water culture experiments. Tomato seedlings failed to grow in raw peat extract, but grew well, flowered, and produced fruit in extract from the treated peat. Similar results were obtained with buckwheat, radishes, and barley.

As no trace of nitrate was found in the peat extract the author concludes that the plants draw their supply of nitrogen from the organic forms of nitrogen in the solution.

Forms of nitrogen compounds in the soil which are direct sources of nitrogen for the higher plants, G. A. RITTER (*Internat. Mitt. Bodenk.*, 2 (1912), No. 6, pp. 533-540).—From a review of various investigations it is concluded that where, as in the case of moor soils, there is little or no nitrate formation, ammonia compounds and other soluble nitrogenous substances in the soil supply the demands of the higher plants for nitrogen.

Conditions affecting the availability of nitrogen compounds in vegetation experiments, II, J. G. LIPMAN, A. W. BLAIR, I. L. OWEN, and H. C. McLEAN (*New Jersey Stas. Bul.* 257, pp. 3-45, pls. 6, figs. 7; *Rpt.* 1912, pp. 205-248, pls. 6, figs. 7).—This is an account of a continuation of experiments begun in 1911 (*E. S. R.*, 28, pp. 724, 725).

"All of the experiments were carried out in glazed earthenware pots, holding 20 lbs. of pure quartz sand. To this sand there was added for each pot 4 gm. acid phosphate, 2 gm. potassium sulphate, 5 gm. calcium carbonate, 0.5 gm. magnesium sulphate, and 0.25 gm. ferric sulphate. The pots were kept in the open with a provision for covering with canvas at night and during rainy weather. The moisture was kept at 9 to 10 per cent by weighing the pots from time to time, and replacing the loss thus indicated. Barley was planted in all the pots and was allowed to grow to maturity, or as nearly so as was practical, and was then harvested, dried, and the total dry weight recorded. The sample thus prepared was ground and nitrogen determinations made [to give] the total nitrogen in the crop. The pots were run in duplicate, and all nitrogen determinations were also made in duplicate. . . . One set of pots was always run without the special treatment, as a check."

Summarizing the results it is stated that "when sand is mixed in varying proportions with shale soil, the yield of dry matter and the percentage of nitrogen recovered from barley, when nitrate of soda is used, are greater with from 10 to 70 per cent of sand than they are with either the pure soil or with higher percentages of sand. The highest point for yield of dry matter and percentage of nitrogen recovered is reached with 40 per cent of sand.

"The yield of dry matter and the percentage of nitrogen recovered from barley, when dried blood was used, are lower with 40 per cent of sand than with shale soil or with lower percentages of sand. With 50 per cent of sand the yield of dry matter and nitrogen recovered are higher than with 40 per cent. With higher percentages of sand there is a decline in dry matter and percentage of nitrogen recovered, but this decline is much more gradual than it is when nitrate of soda is used.

"The yield of dry matter in the barley on the check cylinders is not, with any of the dilutions, as great as the yield with nitrate of soda or dried blood.

"With a residual crop of buckwheat none of the nitrogen of the nitrate of soda was recovered from any of the cylinders having sand mixed with the soil. A small amount was recovered from the shale soil.

"With the residual crop some nitrogen was recovered where blood was used in each of the ten series. The decline in the recovery with increased quantities of sand was very gradual.

"In the residual crop the yield of dry matter was lowest with nitrate of soda, and highest with blood. The yield from the check cylinders would approximate an average of the other two.

"From this work it seems safe to conclude that it is needless to expect any residual effects from moderate applications of nitrate of soda on open sandy soils. Some residual effects may be expected on such soils from dried blood or other organic fertilizers of a similar character.

"The actual net recovery of nitrogen from the humus of the shale soil, which contained varying proportions of sand, is greater in nearly every case than the theoretical amount as calculated from the recovery from pure shale soil. Mixing sand with heavy shale soil permits better aeration and drainage, and results in a more complete utilization of the nitrogen that is present."

Experiments on the accumulation and utilization of atmospheric nitrogen in field soils, J. G. LIPMAN, A. W. BLAIR, I. L. OWEN, and H. C. McLEAN (*New Jersey Stas. Bul.* 258, pp. 3-24; *Rpt.* 1912, pp. 248-269).—One series of experiments reported in this bulletin was conducted on twentieth-acre plats of gravelly clay loam deficient in nitrogen, the object being "to study the influence of small quantities of cow manure and of the bacteria in it on the decomposition of green manures." Corn was followed by crimson clover and rye as green manures to which were added in different series 50, 100, and 200 lbs. of well-rotted manure broadcast over the green manure before plowing under. Wheat was then seeded.

There was no appreciable improvement of the first crop (corn) in 1908 on manured plats. "In the crops for 1909, 1910, 1911, and 1912 there was with only slight exception a better yield of both dry matter and nitrogen on the plats that received manure than on the check plats. However, the plats that received the most manure did not, in many instances, give the largest yield. On the contrary, the plats that received the smallest application of manure did, in a number of instances, give the largest yields. It therefore appears that the beneficial effects of the manure were physical and biological rather than chemical."

As a rule the plats green-manured with a legume gave a larger yield and crops richer in nitrogen than those green-manured with rye.

In a second series of experiments wheat and rye were grown continuously with and without legumes.

Comparing the 1909 yield of grain, total dry matter, and total nitrogen from the nonlegume plats, both wheat and rye, with those for the 1910, 1911, and 1912 crops there is shown a falling off in yield. On the legume plats there was practically no loss in any case and substantial gains in some instances. "This clearly indicates an improved condition of the soil and shows that it is not only not losing in fertility, but that it is slowly gaining. That is, the nitrogen supply is being kept up by the legume crop, while the land is being continually cropped to rye and wheat. The nonlegume plats are gradually becoming poorer in nitrogen. Without the application of stable manure or commercial nitrogenous materials, the legume plats are producing at the rate of 22 to 30 bu. of grain per acre, are apparently gaining in nitrogen and therefore in humus, and are each year assuming a better mechanical condition, with an extra cost over the nonlegume plats of only about \$4.50 per acre."

Peculiarities regarding the nitrate formation and the nitrate content in moor soil, G. A. RITTER (*Internat. Mitt. Bodenk.*, 2 (1912), No. 5, pp. 411-428).—An investigation of the relations between nitrate formation and nitrate content in moor soils is reported.

In the majority of the samples tested there was found little tendency toward nitrate formation, and in most cases there appeared a reducing tendency instead. Also, few of the moor soils showed the presence of nitrates. It is stated as causes for this that moor soil does not afford a suitable medium for the existence and activity of nitrifying organisms, and that the chemical composition is such as rapidly to reduce nitrates and ammonia rather than to oxidize them. Denitrifying organisms are not thought to play an important part in the reduction of the nitrates in these soils since a steady reduction of nitrates was found in a sterilized humus. From the difficulty experienced in detecting nitrifying organisms under the conditions encountered in the moor soils, and from the fact that nitrates were found in some cases, it is thought that these nitrates may have originated from the action of hitherto unknown nitrifying organisms, but that the conditions encountered in general indicate that the presence and formation of nitrates in these cases is due to a purely chemical oxidation of organic matter.

New nitrogenous fertilizers, A. STUTZER (*Illus. Landw. Ztg.*, 33 (1913), No. 93, p. 839, fig. 1).—Brief reference is made to the possible use as fertilizer of guanidin and urea and nitrates of these compounds derived from calcium cyanamid.

Tests of the agricultural value of Burkheiser salt, M. DE MOLINARI and O. LIGOT (*Ann. Gemblour*, 23 (1913), No. 12, pp. 619–625, figs. 2).—This material, which is a crude ammonium sulphate, obtained by a special process as a by-product of gas making, was tested in pot experiments on soil and sand with oats, the general conclusion being that the fertilizing value of the salt was practically the same as that of ammonium sulphate.

The influence of ferrous sulphate and gypsum on crop yield and nitrogen recovery, J. G. LIPMAN, A. W. BLAIR, I. L. OWEN, and H. C. McLEAN (*New Jersey Stas. Rpt.* 1912, pp. 270–277).—The results of four years' plat experiments with corn, oats, wheat, and timothy, using ferrous sulphate at rates of 50, 100, and 200 lbs. per acre and gypsum at rates of 200, 500, and 1,000 lbs. per acre in connection with other necessary fertilizing materials, are reported.

The results show that there was an increase in dry matter and total nitrogen in every case where iron sulphate was used. The plat receiving iron sulphate at the rate of 100 lbs. per acre made the greatest gains in total nitrogen in every case and the greatest gains in crop and total dry matter in nearly every instance. As a rule, the plat receiving iron sulphate at the rate of 200 lbs. per acre made the least gain.

The corn crop on the plat receiving gypsum at the rate of 1,000 lbs. per acre made gains in grain, dry matter, and nitrogen comparable with those made on the plat receiving 100 lbs. of iron sulphate. The other gypsum plats either made only slight gains or yielded less than the check plat.

Magnesia in agriculture, A. HUTIN (*Bul. Assoc. Chim. Sucr. et Distill.*, 31 (1913), No. 5, pp. 347–351).—This article discusses briefly the relation of magnesia to nitrification in soils and the growth of plants. A number of determinations showing the relation of total and soluble magnesia and the lime-magnesia ratio of a coastal plain sugar-cane soil in Peru are reported, and comparing these data with the growth of cane the author reaches the general conclusion that cane is able to accommodate itself to soils which contain from 1.5 to 4 times as much lime as magnesia.

The fish-scrap fertilizer industry of the Atlantic coast, J. W. TURBENTINE (*U. S. Dept. Agr. Bul.* 2, pp. 50, pls. 6).—This bulletin presents a summary of information regarding the history and present status of the fish-scrap fertilizer industry in terms of equipment and output and its proposed and possible development, including a discussion of the particulars in which the processes now

in vogue could be improved and the means whereby the industry could be put on a more secure economic basis.

It is stated that there are at present over 40 factories on the Atlantic seaboard which manufacture fish scrap, including only those whose main output is fish scrap and fish oil. These are distributed as follows: Maine and Florida, 1 each; Connecticut and Delaware, 2 each; New York, 3; New Jersey, 5; North Carolina, 11; and Virginia, 21. The output of these factories in 1912 is stated to have been: Maine, 100 tons acid and 250 tons dry scrap; Connecticut, 1,500 tons acid and 6,500 tons dry; New York, 19,800 tons acid; New Jersey, 530 tons acid and 1,500 tons dry; Delaware, 6,312 tons acid and 500 tons dry; Virginia, 34,000 tons dry; North Carolina, 7,250 tons dry; and Florida, 160 tons dry.

The character, habits, and economic value of the menhaden and other fish used in the industry are discussed and the methods of catching the fish and working them up into scrap and oil are described. Data are also given regarding the composition and uses of the products, including that of using the scrap as a cattle feed.

Inspection of commercial fertilizers, H. D. HASKINS, L. S. WALKER, C. P. JONES, and W. S. FROST (*Massachusetts Sta. Bul.* 147, pp. 96).—This bulletin gives a detailed report on fertilizer inspection in Massachusetts in 1913, including analyses and valuations of 541 samples of mixed fertilizers, fertilizing materials, and lime products. It discusses valuations, cost and quality of fertilizers sold in the State, commercial shortages in both unmixed fertilizing materials and mixed goods, and the economy of purchasing only high-grade fertilizers.

A brief account is also given of comparative tests of various stone meal fertilizers. These experiments were made with corn, oats, and potatoes. There was apparently some slight benefit from the use of the ground rock fertilizers, but not such as to justify the extravagant claims made by the manufacturers of these products.

Average composition of commercial fertilizers from 1880 to 1912, C. S. CATHCART (*New Jersey Sta. Rpt.* 1912, pp. 36-38).—The average composition of each year's output of mixed fertilizers as inspected by the station from 1880 to 1912 is shown in a table. The number of samples upon which the averages are based increased from 93 in 1880 to 847 in 1912. The only marked change in composition was the increase of potash from 2.71 per cent in 1880 to 6.71 per cent in 1912.

Analyses and valuations of commercial fertilizers, fertilizer supplies, and home mixtures, C. S. CATHCART ET AL. (*New Jersey Sta. Bul.* 259, pp. 3-41).—This bulletin reports analyses and valuations of 539 samples of fertilizing materials representing a part of the samples of such materials collected during the season of 1913.

Report on commercial fertilizers, 1913, E. H. JENKINS and J. P. STREET (*Connecticut State Sta. Rpt.* 1913, pt. 2, pp. 97-180).—Analyses and valuations of 894 samples of fertilizers collected and examined during the 1913 inspection are reported and the character of the raw materials of fertilizers examined is discussed.

Analyses of commercial fertilizers, B. L. HARTWELL ET AL. (*Rhode Island Sta. Insp. Bul.*, 1913, Oct., pp. 3-12).—This is the third and last report on analyses and valuations of fertilizers collected during 1913.

AGRICULTURAL BOTANY.

Heredity of quantitative characters, A. B. BRUCE (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps.*, 1911, pp. 96-98).—The author states that it can not be affirmed with certainty that Mendelian laws apply to quantitative

characters. It is suggested that possibly increase of vigor in hybrids will be found dependent on an aggregate of dominant characters.

An examination of the theory of factors by the methodical recrossing of hybrids, E. VON TSCHERMAK (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, pp. 91-95, pls. 10*).—A test was made of the theory of factors, according to which certain units, acting either independently or in cooperation, give rise to the visible characters of species and races. This theory is held to give a satisfactory explanation both of the production of new forms resulting from hybridization and also of complicated cases of Mendelian inheritance.

Reduplication of terms in series of gametes, W. BATESON and R. C. PUNNETT (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, pp. 99, 100*).—The authors present a new explanation of the phenomena of coupling and repulsion and state that evidence has been found which proves that these are influences of the same phenomenon and that in each the effects are produced by reduplication of those gametes which represent the parental characters.

Concerning geographical races with fixed and variable characters, J. V. VIVIAND-MOREL (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, pp. 266-274*).—A review is given of a study of a large number of Linnæan types of plants indigenous to France and other parts of southern Europe and northern Africa, from which the author concludes that the races which compose the original types do not in all cases possess fixed characters. In the case of perennial and shrubby plants they seldom breed true, although in annual species the great majority of such forms reproduce themselves by seed.

Mendelism and acclimatization, H. NILSSON-EHLE (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, pp. 136-157*).—The author claims that his experiments with cereals indicate that there is a certain relation between the adaptive changes of plants called hereditary acclimatization and the regrouping of Mendelian factors. Acclimatization is believed to be due to a regrouping of the components or Mendelian factors already existing, resulting in more advantageous combinations.

Variation in first generation hybrids: Its possible explanation through zygotaxis, W. T. SWINGLE (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911 pp. 381-394, figs. 10*).—The author describes experiments conducted under the auspices of this Department in crossing various Citrus species, and accounts for the variation by the positional relation of the chromosomes. He suggests for this supposed positional influence the name zygotaxis, and by this he means the arrangement in the syngamete or zygote of the chromatin and other hereditary substances derived from the parental gametes and the persistence of this arrangement in the cells produced by the subdivision of the syngamete.

Mosaic heredity, L. BLARINGHEM (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, pp. 101-131, figs. 19; abs. in Bul. Soc. Bot. France, 60 (1913), No. 4, pp. 282, 283*).—The author designates as mosaic heredity that method of special transmission by which is manifest in the descendants the corresponding characters of the parents. Attention was first called to this method by Naudin in 1859, and it is said that it offers analogies to alternate and Mendelian heredity. The author describes a number of examples of this form of heredity and discusses their common characters and means for distinguishing them from the so-called graft hybrids.

A bibliography is appended.

Is the law of uniformity of hybrids of the first generation absolute? M. R. GARD (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, pp. 197-200*).—The author states that although Naudin concluded from his experiments that all hybrids derived from a cross resemble each other in the first gen-

eration, as a result of his own experiments in hybridizing a number of species of *Cistus* he considers that these conclusions are not confirmed.

Two species derived from a hybrid when crossed with each other do not obey the Mendelian law of dominance, G. BELLAIR (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, pp. 201-203*).—Experiments with some *Nicotiana* hybrids are reported which indicate that at least in this case two species derived from a hybrid when crossed with each other do not obey the Mendelian law of dominance.

The variability of micro-organisms and the inheritance of acquired characters, B. HEINZE (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, pp. 278-289*).—An account is given of variations that have been observed in different bacteria and fungi.

Azotobacter was found subject to morphological change under the influence of external conditions, depending upon the stage of development. If the amount of combined carbon was reduced in the media in which pure *Azotobacter* was cultivated and small quantities of asparagin were given, forms of *A. chroococcum* and of a blue-green alga appeared which seemed very closely related to the colorless forms of *Azotobacter*. This would indicate that *Azotobacter* is not a pure species, but the question is not definitely decided.

Other examples of the influence of the culture media on algae and on *Bacillus prodigiosus* and *B. cyanogenus* are reported.

Mutations in pure lines of beans, W. JOHANNSEN (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, pp. 160-163*).—The author reports the occurrence in pure lines of beans of two mutations. The first appeared in 1903 and was immediately constant, while the second appeared in 1907 and was recognized as being in a heterozygous condition. The first was characterized by great size and the relatively narrow shape of the beans, while the second was a broad biotype which could be extracted from the original heterozygote through segregation.

Grafting and asexual hybridization, E. GRIFFON (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, pp. 164-196, figs. 24*).—Descriptions are given of a number of forms, designated by the author as hybrids, which have occurred as the result of grafting. These include not only annuals and herbaceous perennials, but a number of woody plants as well.

Notes on parthenogenesis in plants, ROSE H. THOMAS (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, p. 209*).—As a result of her experiments the author has proved that parthenogenesis is possible in several species of *Nicotiana* and also in the evening primrose and cucumber. Parthenogenetic seeds from these plants were found to reproduce the parental type and the plants were normal and bore fertile anthers.

Genetic and nongenetic factors in the improvement and breeding of new varieties, A. L. HAGEDOORN (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, pp. 132-135*).—Attention is called to the genetic and environmental factors that influence plant breeding, and the author urges that special care be given to all F_1 individuals so that the number of second generation hybrids may be increased as rapidly as possible. He claims that the F_1 generation should be especially protected against frost and drought.

The application of the principles of genetics to some practical problems, C. C. HURST (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, pp. 210-221*).—A description is given of the results of hybridizing garden peas, sweet peas, orchids, primulas, snapdragons, barberries, forest trees, fruit trees, cabbage, etc.

A study of abnormal characters in seedlings, with a view to obtaining new varieties, N. STRAMPELLI (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et*

Raps., 1911, pp. 237-246, figs. 11).—The author gives an account of experiments with wheat and various species of Leguminosæ, the object being to test the value of selecting those seedlings representing abnormalities as a possible means of developing new varieties.

In the case of wheat, precocity of development was found to be an inherited character, and two forms were obtained which were characterized by marked precocity, short stalk, and stiffness of straw. With alfalfa, clover, and sainfoin, only a small proportion of the descendants possessed the abnormal type.

The breeding of double flowers, EDITH R. SAUNDERS (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps.*, 1911, pp. 397-405).—In this paper the author deals with a number of practical questions relating to the breeding of double-flowered plants. She distinguishes three types or grades of doubling. In the first the flower becomes so double that neither pollen nor ovules are produced. In the second the organs of only one sex are aborted, while those of the other remain functional. In the third, which is by far the largest class, doubling occurs without loss of function in the reproductive organs of either sex.

Considering the question of singleness or doubleness, it is stated that singleness is due to the presence of two factors while doubleness is due to the absence of either or both of them. In the nondoubling single type these factors are linked together, while in the eversporting single type the factors are not linked. All four combinations of the allelomorphs occur among the ovules in an ever-sporting single, but the pollen appears unable to carry the two factors, either alone or together. This is said to be a case of what has been termed partial coupling combined with a sex limited distribution of the factors.

A popular account of this investigation has been noted elsewhere (*E. S. R.*, 29, p. 341).

Hybrids between species of *Antirrhinum*, J. P. LOTSÝ (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps.*, 1911, pp. 416-428, figs. 9).—A description is given of hybrids grown by the author from seeds produced by E. Baur and crossed on a number of species of *Antirrhinum*. He concludes from his experiments that segregation and the recombination of factors are not limited to hybrids between varieties, but may also occur in hybrids between certain species.

Nicotiana crosses, ROSE H. THOMAS (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps.*, 1911, pp. 450-461, figs. 6).—Descriptions are given of a number of *Nicotiana* hybrids and a detailed account is presented of the differences observed in the pollen grains.

In most species of *Nicotiana* the pollen grains are oval and either large or small. In *N. tabacum* and its allies they are square or approaching that shape, while in *N. sylvestris* they are round. The segregation of pollen was observed in all the different crosses.

Experiments in crossing a wild pea from Palestine with commercial peas with the object of tracing any specific identity between this wild pea and peas of commerce, A. W. SUTTON (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps.*, 1911, pp. 358-367, figs. 4).—An account is given of experiments in crossing a species of peas obtained in Palestine in 1904 with some cultivated varieties of *Pisum sativum* to determine if possible whether the first species could be considered the ancestor of some of the cultivated forms. About 40 crosses were made between this species and *P. sativum* and *P. arvense*, but in only 4 cases were the hybrids carried to the F₃ generation, the others being sterile.

The results obtained can not be considered as demonstrating that the Palestine pea was the forerunner of the present garden peas. While some of the hybrids were fertile, yet the character of the flowers, leaflets, and pods, the

type of seed, and the sterility of most of the hybrids would probably indicate that it is not to be so considered.

The production of varieties of wheat possessing a high degree of baking strength, C. E. SAUNDERS (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, pp. 290-300*).—A description is given of work that has been carried on at the Canada Experimental Farms in an attempt to produce early wheats of a greater degree of strength than those commonly planted.

It was found that strength can not be considered a simple Mendelian character. It depends on numerous factors and is extremely complex, and its inheritance is said to be still far from being understood.

A biometrical study of the seeds of the genus *Brassica*, P. MONNET (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, pp. 406-415*).—The author gives the results of an attempt at a biometrical classification of 8 species and varieties of *Brassica*, preliminary to a study of variability and heredity in these plants.

The development of disease-resistant varieties of plants, W. A. ORTON (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, pp. 247-265, figs. 9*).—A description is given of some of the work of this Department in the breeding of cotton, cowpeas, and melons for disease resistance.

Experiments with peas in one variety of which the seeds adhere to each other, P. DE VILMORIN (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, pp. 368-372, figs. 2*).—The author crossed a variety of peas characterized by the adherence of the peas in the pod with other varieties to determine whether this character of adhesion would be inherited. A study of the third generation shows that there is apparently some connection between the factors for type of foliage, pigment, and the adhering character.

Variability in seeds, B. D. HALSTED ET AL. (*New Jersey Stas. Rpt. 1912, pp. 386-395, pls. 3*).—A study was made of soy beans, pea beans, cowpeas, and Lima beans to determine the relation of location in the pod to the size of the seed. In the soy beans it was found that the tip seeds in the three-seeded pods were the heaviest and the middle seeds next. In the pea beans the seeds nearest the middle of the pod were the heaviest and those at the end the lightest, the basal ones being the lightest of all. In the cowpeas the middle seeds were the largest and those at the tip the lightest. In the Lima beans all the basal seeds were the lightest in their respective sets, the tip seeds being the heaviest in the two-seeded and lightest in the four-seeded pods.

A study was also made of position and desirability of seeds, these being grouped according to seeds of average size, exhibiting plumpness and maturity, these being taken as the standard, and those below the average, which were considered imperfect. In the soy beans and in the Lima beans with a single exception the largest percentage of standard seed was from the tip portion of the pod and in the cowpeas from the middle position of the pod.

Additional notes are given on the position, attachment, and development of the seed in the pods of a number of leguminous plants.

Study of the hypocotyl in the field, B. D. HALSTED ET AL. (*New Jersey Stas. Rpt. 1912, pp. 395-397, pl. 1*).—A note is given on investigations begun to determine the inheritance of length of hypocotyl in field grown plants. This work has been taken up with soy beans, pea beans, and sunflowers, and the material collected for further study.

The study of the hypocotyls of some root crops, B. D. HALSTED ET AL. (*New Jersey Stas. Rpt. 1912, pp. 397, 398, pl. 1*).—A brief report is given of a study of the hypocotyl of radish plants, in which the development of the hypocotyl is traced from the seedling stage to the mature root.

The failure of plants grown in window boxes to develop fleshy roots is attributed to the abnormal elongation of the hypocotyl, and it was found that when the hypocotyl elongates to twice or more its normal length all power of transforming into a thickened root is lost.

Observations made on a number of other root crops show that the same phenomenon is possessed by them as the radish.

Tuber formation by potato, G. BAUER (*Natur*, 17 (1912), p. 363, fig. 1; *abs. in Bot. Centbl.*, 123 (1913), No. 9, pp. 218, 219).—A potato plant grown in good soil in a flower pot and covered with a dark pasteboard cylinder during most of the early and all of the latter portion of its growth, was found in September to have well developed tubers and to bear normal leaves on the part grown in exposure to light.

The effects of assimilation in cultivated plants, S. STRAKOSCH (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps.*, 1911, pp. 275-277).—The author has attempted to estimate the value of the materials taken from the soil by various cultivated plants. The estimation of the nutrients consumed by the plant is made from a chemical analysis of the entire plant, and the value of the produce is calculated according to the physiological values of the utilizable substances harvested. Taking the value of the elements absorbed from the soil as 1, the different crops reported ranged from 1.6 to 24.75. Oats are given at 3.25; wheat, 4; barley, 4.5; potato, 5.5; sugar beets, 9.3; alfalfa, 12.75; and sainfoin, 20.75.

Alternations of humidity and dryness as affecting germination of seeds of some weeds, O. MUNERATI and T. V. ZAPPAROLI (*Staz. Sper. Agr. Ital.*, 46 (1913), No. 3, pp. 157-195).—Pursuant to work previously reported (E. S. R., 28, p. 427), the author gives tabular details of studies, on about 30 kinds of seeds, carried out under controlled conditions from the summer or fall of 1910 through May of 1912.

It is stated that among the plants which germinate slowly and partially when kept in a constantly moist medium, but quickly and in high percentages when brought into a humid atmosphere after long dryness, are *Avena fatua*, *Galium aparine*, *Papaver rhæas*, *Plantago lanceolata*, and *Amarantus retroflexus*. Among those which germinate in low percentages in alternating humidity and dryness are *Rapistrum rugosum*, *Myagrum perfoliatum*, *Sinapis arvensis*, *Salvia pratensis*, *Abutilon avicennæ*, *Setaria italica*, and *Oenothera biennis*. Among those which may long retain vitality without germination in a medium alternating between humidity and dryness are *Convolvulus sepium*, *Lappa major*, *Sorghum halepense*, and *Solanum nigrum*. Among those apparently but little affected by variations of humidity are *Vicia segetalis*, *V. cracca*, *V. hirta*, *Lathyrus aphaca*, *Cirsium arvense*, *Eruca sativa*, *Daucus carota*, and *Cuscuta epithymum*. *Panicum crus-galli* and *Rumex crispus* are among those which, while germinating more or less in any sort of alternations of humidity and dryness, do not germinate in continuous humidity but are able to retain long their vitality.

Influence of manganese sulphate on germination, J. CROCHETELLE (*Jour. Agr. Prat.*, n. ser., 26 (1913), No. 39, pp. 398, 399).—Reporting results of experiments carried out with seeds of several common plants subjected to the action of manganese sulphate in different strengths, the author states that the species tested behaved very differently at different concentrations. The germination of clover fell off very rapidly at concentrations above 1 per cent, the cereals appearing more indifferent to an increase of concentration. In limy clay soil 2 concentrations favorable to germination were found, one about 0.1 to 0.2 per cent, the other about 0.8 to 1 per cent.

Influence of external conditions on resistance to cold by perennial plants, A. WINKLER (*Jahrb. Wiss. Bot. [Pringsheim]*, 52 (1913), No. 4, pp. 467-506, fig. 1; *abs. in Riv. Patol. Veg.*, 6 (1913), No. 7, p. 221).—Details and tabulated results are given of experiments on many deciduous and evergreen plants, all of which were able to bear a temperature of -20° C. in winter. When gradually approached, a winter temperature of -30° was borne, the younger evergreen foliage proving more resistant than the older. In the growing period newly formed buds and foliage of evergreen withstood -3 to -5° . The resting buds, the older assimilating organs, and the wood of evergreens bear in summer temperatures of -8 to -10° .

Trees accommodate themselves quickly to low temperatures, the wood of evergreens exceeding the mature needles and leaves in this respect, and these in turn greatly exceed young leaves and buds, in case of which accommodation extends readily beyond -5° but not to -15° . Leaves of evergreens and twigs of other trees can endure, from 4 to 6 times, if gradually approached, temperatures below their ordinary death point. Osmotic pressures and turgor are heightened in cold.

A bibliography is appended.

FIELD CROPS.

[Cost of production of different farm crops at the New Jersey Stations] (*New Jersey Stat. Rpt.* 1912, pp. 173-193).—In this report the costs of different crops produced on the college farm, as derived from careful records kept of each field, are given.

The record for timothy hay showed a value per acre of \$67.90, an average cost per acre \$32.69, and an average cost per ton \$9.78. The record for alfalfa showed a value per acre of \$49.68, a cost per acre of \$5.21, and an average yield per acre of 2.72 tons. For another field the value per acre was \$40.73, the cost per acre \$8.29, and the yield 2.4 tons. Another field of 9 acres showed an average total cost per acre of \$25.76 in seeding it to alfalfa. The record of a crop of oats and peas for forage showed a value per acre of \$38.33, a cost per acre of \$29.79, and a yield of 2.4 tons. The cost of sowing a cover crop of rye and vetch was \$14.54 per acre. Another field of oats and peas showed a value per acre of \$26.94, and a cost per acre of \$20.70.

The record of a corn silage crop showed a value per acre of \$28.90, a cost per acre of \$19.09, and a yield per acre of 6.2 tons. Records of another field showed a crop value of \$34.69 per acre, a cost of \$19.47 per acre, and a yield of 6.4 tons per acre. The cost of seeding a cover crop of wheat and vetch was given as \$3.22 per acre.

Similar data are also given for other crops, and copy of the record time sheet is presented.

Twenty-third report of cooperative field experiments, 1911-12, B. R. LARSEN ET AL. (*Aarsber. Norges Landbr. Høiskoles Akervekstforsök*, 23 (1911-12), pp. 123+15).—This report gives the usual accounts of an aggregate of 280 variety tests and fertilizer trials conducted during the year at farms in different parts of Norway under the direction of the Aas Agricultural College (E. S. R., 23, p. 432). The results of the following series of trials are discussed in detail: Twelve years' comparative variety tests of spring grains under different conditions of growth; trials with 3 different amounts of seeds of oats and barley, 1899-1911; 8 years' comparisons of sprouted and unsprouted seed potatoes; and 9 years' comparisons of potato varieties grown on 84 trial farms in different parts of Norway, 1904-1912.

The removal of mineral matter from unfertilized soil by different varieties of plants, I, A. STRIGEL (*Landw. Jahrb.*, 43 (1912), No. 3, pp. 349-366).—This paper reports the results of determinations of the ash and nitrogen content of 4 legumes and 5 grass varieties grown for this purpose in 1906 and 1907 (see below), and also those of 12 native plants mostly classed as weeds. The figures are presented in numerous tables of comparisons in various relations, and the results are discussed. Analyses of samples of the surface and subsoil taken each year from the plats are shown.

Percentage of ash constituents in the dry matter of legumes and grasses.

The influence of botanical composition, of origin, and of harvest time on the chemical composition of hay, II, A. STRIGEL (*Landw. Jahrb.*, 43 (1912), No. 3, pp. 366-371).—Analyses of hay samples from East Prussia averaged richer in protein and fat and poorer in crude fiber than those from the experiment field in Berlin. Hay samples from Oberlausitz ranked between the legumes and grasses of the Berlin field in nitrogen, crude fiber, and carbohydrates, but were richer than either in fat and ash. The calcium and magnesium in the dry matter was about midway between that in the legumes and grasses. The content of potash, sodium, phosphoric acid, chlorin, and especially silica, was higher than in either of the Berlin crops. It is noted that in general the predominance of one plant species or another would change the composition of the dry matter or of the ash, but that this difference is not so marked as the difference between the Papilionaceæ and Gramineæ.

The percentage of organic substances in the dry matter changed with the time of harvest, but not uniformly, while the ash constituents showed greater regularity. As the season progressed the hay showed an increase of calcium and magnesium; at first a reduction then a slight increase in potash; and at first an increase then a reduction in sodium. The percentage of phosphorus in the hay diminished from the early to the normal cutting time. Sulphuric acid, chlorin, and silica showed an increase during the season.

✓ Range improvement by deferred and rotation grazing, A. W. SAMPSON (*U. S. Dept. Agr. Bul.* 34, 1913, pp. 16).—In this bulletin the author discusses the causes of deterioration in ranges, the requirements of plant growth, the maintenance of a maximum forage crop, and the application of a system of deferred grazing to range management. It is claimed that deferring grazing over a portion of the range until the seed has matured, and then grazing it to avoid loss of forage* through nonuse, and to assist reproduction by trampling in the seed restores and maintains the vegetation without the loss of the forage crop in any year, insures the seed being planted, thereby overcoming the chief disadvantage of year-long protection, and does away with the fire danger resulting from the accumulation of inflammable material under year-long protection.

Experimental cultures of pure types of cereals, [with] observations on the stability and variability of their characters, BŒUF (*IV. Conf. Internat.*

Génétique Paris, Compt. Rend. et Raps., 1911, pp. 319-327).—"A pure variety of cereal must be regarded as a natural type which it is impossible to modify by any direct action. The hereditary characters of such a type depend on the ancestry; the variable characters depend on the conditions of life; selection of individuals is without effect. By the selection of large grains an increase in the yield may be obtained under certain conditions and within limits which our experiments have not yet fixed. The only means by which improvements can be effected are by bringing to perfection cultural methods, in the production of new types by hybridization, and in taking advantage of fortuitous variations, of which many owe their origin to natural hybridization."

Right- and left-handedness in cereals, R. H. COMPTON (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, pp. 328-331*).—The author gives the results of observations of not less than 19,165 barley seedlings, 469 oat seedlings, and 6,189 maize seedlings, his conclusions being substantially as previously noted (*E. S. R., 27, p. 236*).

Fertilizing cereals, A. ZARAGÜETA (*Prog. Agr. y Pecuário, 18 (1912), Nos. 788, pp. 547-550; 789, pp. 563-567, figs. 10*).—In fertilizing wheat a yield of 2,120 kg. of grain per hectare (1,887 lbs. per acre) followed an application of 360 kg. superphosphate, 120 kg. ammonium sulphate, 100 kg. nitrate of soda, and 100 kg. potassium chlorid; 1,480 kg. was produced without the potassium chlorid and 1,050 kg. without any fertilizer. The apparent increases in yields by the use of fertilizers ranged from 1,247 to 2,967 kg. per hectare with barley, 730 to 1,720 kg. with oats, and 320 to 1,905 kg. with rye.

On the cultivation and inoculation of legumes, A. EICHINGER (*Pflanzer, 8 (1912), No. 4, pp. 190-219*).—This article discusses the cultivation and usefulness of the following legumes: As green manures, beggar weed (*Desmodium tortuosum*), Jack beans (*Canavallia*), soy beans, cowpeas, red clover, peanuts, velvet beans (*Mucuna utilis*), Japan clover (*Lespedeza striata*), *Medicago arborea*, Mexican clover (*Richardsonia [scabra] glabra*), *Indigofera galeoides*, indigo (*Tephrosia purpurea*), and yellow trefoil (*Medicago lupulina*); alfalfa, beggar weed, red clover, white clover, crimson clover, and cowpeas as forage plants; and soy beans, garden beans, lentils, and Jack beans (*Canavallia ensiformis*) as grain crops.

Experiments in inoculation showed in general a considerable increase by the addition of bacteria, whether by pure cultures, the introduction of tubercles, or otherwise.

Phosphorus for alfalfa fields, J. E. WING (*Breeder's Gaz., 64 (1913), No. 3, p. 89, fig. 1*).—This article relates instances in which annual applications of 400 lbs. of acid phosphate per acre as a top-dressing greatly increased the yields of hay, in some cases approaching 200 per cent. The influence of the phosphorus is ascribed not only to its direct manurial value but also to its favorable influence on bacterial development.

Alfalfa in South Carolina, A. G. SMITH (*South Carolina Sta. Circ. 19, pp. 22, figs. 3*).—The author discusses the following topics with special reference to South Carolina conditions: Who should plant alfalfa; alfalfa versus other hay crops; adaptation of soils; injurious weeds, including crab grass, Bermuda grass, and nut grass; preceding crops; seed and time of seeding; preparation of the land; liming; fertilization before and after planting; inoculation; planting; cutting and curing the hay; pasturing; cultivating; diseases; yields and life of alfalfa; and reseeding an old field.

Mosaic inheritance in the hybrids of barley, L. BLAIRINGHEM (*Compt. Rend. Acad. Sci. [Paris], 156 (1913), No. 13, pp. 1025-1027*).—The author presents data on the behavior of the transmission of the awn and awnless characters in crossing 5 varieties of barley and their reciprocals, viz, *Hordeum distichum*

nutans×*H. distichum nudum*, *H. distichum erectum*×*H. distichum nudum*, *H. coeleste trifurcatum*×*H. distichum nutans*, *H. coeleste trifurcatum*×*H. zeocriton*, and *H. coeleste trifurcatum*×*H. steudellii*. It is pointed out that the rules of heredity discovered by Naudin have special application in crossing different species and govern the character of abortiveness in such crosses. See also another article abstracted on page 328 of this issue.

Behavior, under cultural conditions, of species of cacti known as *Opuntia*. D. GRIFFITHS (*U. S. Dept. Agr. Bul. 31, pp. 24, pls. 8, fig. 1*).—This bulletin records observations taken at Brownsville and San Antonio, Tex., and Chico, Cal., on between 600 and 1,500 varieties of prickly pear and cane cacti. Notes and discussions include spine variation, adaptability to conditions, excessive development of spicules, locality variations, effect of housing, longevity, effect of low temperatures, coloration, proliferation of fruit, habits of the plants, and moisture requirements.

It is noted that "all forms thrive best when the moisture supply is low during the dormant season. Wherever tried, some species or form native to the region has proved more productive than introduced forms. . . . Considering the succulence of the plants, their power of recovery from the effect of low temperatures is remarkable. Large limbs which hang limp beside the plants will often regain their normal position upon the advent of growing weather, provided they are not disturbed while the weather is cold. . . . Proliferation of fruit is not necessarily a specific characteristic but may be brought on by extraneous conditions. If this habit could be induced in the economic forms their value for forage would be decidedly increased. In all of the larger species especially, the plants grown from cuttings and those grown from seed present a very different appearance; the latter are treelike and the former are headed on the ground without distinct stems."

The result of selecting fluctuating variations, F. M. SURFACE (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, pp. 222-236*).—The author gives the results obtained at the Illinois Experiment Station in the production of high protein, low protein, high oil, and low oil varieties of corn as previously noted (*E. S. R., 20, p. 531*).

Inheritance of waxy endosperm in hybrids of Chinese maize, G. N. COLLINS and J. H. KEMPTON (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, pp. 347-357*).—More detailed results are given of a series of crosses between Chinese corn with waxy endosperm and American varieties with horny endosperm, previously noted (*E. S. R., 29, p. 35*). "For the whole series of crosses the percentage of waxy seeds was 23.1, a deviation from the expected 25 of over 9 times the probable error.

"Where a Chinese variety with colorless aleurone was crossed with an American variety with colored aleurone, the second generation showed a coherence or positive correlation between waxy endosperm and colorless aleurone. Where the Chinese parent had a colored aleurone and the American parent was white, the positive correlation was between the opposite characters, waxy endosperm and colored aleurone. These results are interpreted as showing a definite tendency for characters that are associated in the parents to appear together in the later generations of the hybrids. Similar examples of coherence have been reported in the other crop plants, though this seems to be the first instance where the correlation is reversible."

See also a previous note by Collins (*E. S. R., 29, p. 633*).

Corn improvement (*Arkansas Sta. Bul. 115, pp. 549-574, figs. 14*).—The first portion of this bulletin, by C. V. Ruzek, discusses the buying, selection, and storing of seed corn; describes methods of germination tests; and points out good and poor characteristics of ears and kernels. The second portion, by

M. Nelson and C. V. Ruzek, describes 8 varieties of corn suitable for Arkansas conditions.

The shrinkage of shelled corn while in cars in transit, J. W. T. DUVEL and L. DUVAL (*U. S. Dept. Agr. Bul.* 48, pp. 21, figs. 8).—This bulletin reports a continuation of work already noted (*E. S. R.*, 25, p. 638). Data are given regarding 4 shipments of cars of corn loaded at Baltimore for Chicago, including percentage of moisture and sound corn, weight per bushel, percentage of cob, dirt, and badly broken kernels, temperature of corn when loaded and unloaded, and net weight.

The summary of the results of three of these experiments shows that the average natural shrinkage in 12 cars of corn in transit from Baltimore to Chicago and return amounted to 0.33 per cent, while in 12 duplicate cars held on the track at Baltimore it was 0.41 per cent. The average temperature at the time of unloading the corn in the 12 cars that were shipped was 60°, as against 64° F. for the cars held at Baltimore, this difference being accounted for by the fact that the temperature of the air through which the cars passed en route to Chicago and return was usually lower than that of the air surrounding the cars at Baltimore.

The authors maintain that there is unquestionably a natural shrinkage in commercial corn during transit and in storage, varying with the moisture conditions of the corn and the atmospheric conditions to which it is exposed. It is very rapid in corn that has become hot and sour, and may amount to several per cent within a few days.

Cotton breeding experiments and valuation of individual plants in cotton breeding, B. WUNDER (*Pflanzer*, 8 (1912), No. 7, pp. 398-411).—The author presents the following formula for placing a value on individual plants for use in making comparisons for breeding purposes:

$$V = \frac{\% \text{ of lint}}{2} + 2 \times \text{weight of 100 seeds} + \text{staple length} + 10 \times \text{average yield per boll.}$$

The formula employed to determine the relative growth of plants was as follows:

$$\text{Growth} = \frac{\text{number of branches} \times \text{length of stem.}}{2}$$

Tables are given showing the results of the application of these formulas to 365 individual plants grown in 10 different fields.

The inheritance of measurable characters in hybrids between reputed species of cotton, W. L. BALLS (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps.*, 1911, pp. 429-440, figs. 9).—In the crossing of cottons the author has made observations and collected data on the inheritance of a meristic character (number of loculi in the ovary), the weight of the seed, and the length of lint. His conclusions are that "the error from natural crossing is a serious obstacle to precise work on genetics in cotton. The behavior of the foreign pollen is closely analogous to that of a parasitic fungus. The pollen from the F_1 of reputed species-crosses has a higher infection-capacity than that of either parent. The correlation of one character with another causes new dimensional features to appear in the hybrids. The expression of any character is thus determined firstly by its gametic origin, secondly by simple fluctuation, and thirdly by 'autogenous fluctuation'. Even the simplest Mendelian inheritance, viz, the 3:1 ratio, may thus provide an F_2 in which the expression of the character is externally similar to simple chance distribution."

See also a previous note (*E. S. R.*, 28, p. 631).

Propagation of cotton by cuttings, G. CASTET (*Rev. Hort. Algérie*, 16 (1912), No. 5, pp. 144-148, figs. 4).—This article describes the methods employed by means of which herbaceous cotton branches were successfully grown under glass by cuttings or slips, as a means of multiplying an especially promising plant.

Variety tests with cotton, 1912, F. G. TARBON, JR. (*South Carolina Sta. Circ. 11, pp. 3, 4*).—This circular consists of a table giving yields per acre of seed cotton, percentage of lint, and length of lint in inches. Felkel, the variety producing the highest percentage of lint, 42.1 per cent, ranging from $\frac{5}{8}$ to 1 in. in length, was one of the best yielders, producing 1,518 lbs. per acre.

Cotton industry in Southern India, H. D. BAKER (*Daily Cons. and Trade Rpts. [U. S.], 16 (1913), No. 173, pp. 513-516*).—With the introduction of Cambodia cotton Southern India exports have more than doubled in quantity and more than trebled in value within the last decade, or since Tinnevely sorts were grown. It is noted that the Cambodia cotton flourishes as a heavily manured and irrigated crop. Conditions of manufacturing and the status of the industry are also discussed.

The fertility constituents in flax, J. W. INCE (*North Dakota Sta. Bul. 106, pp. 5-9*).—This paper contains data, compiled from various sources, showing that in equal weights "flax-seed contains over twice as much fertility as does the average of the 6 common grain crops cited; that flax-seed contains more manurial value than the highly nitrogenous oil-bearing seeds; that with the exception of potassium, flax-seed contains more fertilizing ingredients than do the seeds of the six legumes mentioned. Again, though flax straw contains less phosphorus and potassium than does the straw of legumes and grains, yet it occupies a position about half way between the latter two with regard to its nitrogen content.

The author believes that inasmuch as flax products are very rich in manurial constituents they should be carefully conserved on the farm.

On the origin of cultivated oats, L. TRABUT (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, pp. 336-346, figs. 10*).—The author concludes that "at least 3 wild species of *Avena*, under the influence of culture, may acquire characters fitting them for cultivation. These 3 species preserve the ancestral characters by which they are adapted to different climates. "*A. fatua* gives rise to oats adapted to temperate and mountainous regions; *A. sterilis*, to oats adapted to the southern countries, and to saline soils; *A. barbata*, to races adapted to dry countries."

See also a previous note (E. S. R., 27, p. 237).

Studies in potato breeding, R. N. SALAMAN (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, pp. 373-376*).—This article gives a résumé of previous work (E. S. R., 24, pp. 429, 632), with more recent results. The characters discussed are shape of tuber, the tuber eyes, color, and disease resistance. Results showed that the shape depended on the length character. "Superficial eyes" were found to be dominant over deep eyes, and color characters were found to follow Mendelian laws with certain compositions of reds and of purples or blacks with their developing pigment when selfed. "Upright" positions of growth were dominant over "proneness." Crossing for disease resistance had not been carried far enough for results. See also a previous note (E. S. R., 28, p. 632).

Experiments on the improvement of rice in Java by seed selection, J. VAN BREDA DE HAAN (*Bul. Écon. Indochine, n. ser., 16 (1913), No. 100, pp. 11-28*).—According to the appearance of the spikes found in some 6,400 samples, 2 groups were made, *Oryza sativa* and *O. glutinosa*. Treatment of the kernels of the 2 groups with a diluted solution of iodine produced a violet color on the surface of those from the *O. sativa* group, and a reddish-brown color in the *O. glutinosa* group. These groups were further divided into 4 varieties, viz, colored glumes, red awns, yellow awns, and awnless. Further divisions were made according to external characters until 751 varieties were obtained in the *O. sativa* group and 141 in the *O. glutinosa* group.

Careful and full data were kept of selections along pure lines resulting in pedigreed varieties grown in various parts of Java. The largest yield mentioned as attained was 6,611 kg. per hectare (5,884 lbs. per acre). Cross breeding is also mentioned as giving satisfactory results, especially with the first generation of hybrids.

The principles of paddy manuring, W. H. HARRISON (*Jour. Bd. Agr. Brit. Guiana*, 6 (1912), Nos. 1, pp. 37-40; 2, pp. 71-77).—From results of manurial tests with rice the following principles are laid down:

"Paddy soils need manuring with bulky organic manures which readily decompose under anaerobic conditions yielding humus. Nitrates are unsuited for the purpose, whereas ammoniacal manures or manures which yield ammonia under anaerobic conditions of fermentation are of great value. Nitrogen and phosphoric acid must be applied to all paddy soils, whereas potash should only be applied when the soil is in particular need of that ingredient."

The crops mentioned as used for green manures are *Sesbania aculeata*, *Crotalaria juncea*, *Tephrosia purpurea*, and *Phaseolus mungo*. Two methods of green manuring were employed, viz, turning under a green crop, and incorporating with the soil green leaves cut and brought from other areas. The latter is mentioned as being most efficient, as phosphorus is also added to the soil, while with a plowed-under crop phosphorus was added in the form of superphosphate. After the addition of green leaves as a fertilizer 4,490 lbs. of paddy and 5,811 lbs. of straw were obtained per acre, after green manure 4,200 lbs. paddy and 4,400 lbs. straw, and 3,392 lbs. paddy and 3,124 lbs. straw with no treatment. In another experiment an addition of 112 lbs. of superphosphate to green manure apparently increased the yield from 2,814 lbs. paddy and 2,691 lbs. straw, to 3,733 lbs. paddy and 4,043 lbs. straw per acre.

A study of the colors of the grain in rye, VON RUEMKE (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps.*, 1911, pp. 332-335).—"Selection according to the color of the grain, the yield, and the hardness, has been continued for 12 years, and the following facts have been established: In order to obtain pure races as regards grain color, selection should be continued for 7 or 8 years. The phenomenon of xenia occurs, as in maize. The color of the grain is a constant character. This color is produced by a pigment in the aleurone layer, next the epidermis. Those races (greenish-blue and yellow) which have hitherto been in commerce are satisfactory both for milling and baking. The different colors of the grain are correlated with other physiological and morphological characters; for instance, the greenish color appears to be connected with an increased tillering capacity and a shorter straw than the yellow colors. The great difficulty in maintaining the purity of a variety of rye, on account of the danger of cross-fertilization, is increased in direct proportion to the size of the neighboring plats of rye.

"The author believes that the possession of races pure as regards color supplies a criterion by which the occurrence of crossing will at once be visible in the grain, and that this will be a material aid in maintaining the purity of varieties of rye."

Soy beans, E. H. JENKINS (*Connecticut State Sta. Bul.* 179, pp. 3-13, figs. 4).—This bulletin briefly describes the soy-bean plant, its composition and yield as compared with some other crops, and its uses as silage, hay, green manure, seed, and hog pasture under Connecticut conditions.

It is noted that the best method of inoculation has been with 500 lbs. of soil per acre from a field where the crop has grown well. For seed production rows drilled 24 to 36 in. apart with seeds 2 to 4 in. apart in the row and for growing forage 1½ bu. seed per acre sowed with a grain drill is advised.

Buckwheat and cowpeas were grown under like soil conditions as soy beans for comparison of their value as cover crops and harvested at the same time with the following results:

Comparative yields per acre in 1913 of soy beans, cowpeas, and buckwheat.

Cover crop.	Total yield.	Water.	Vegetable matter.	Mineral matter.	Nitrogen.	Phosphoric acid.	Potash.
	Lbs.	Lbs.	Lbs.	Lbs.	Lbs.	Lbs.	Lbs.
Soy beans.....	16,877	12,913	3,323	641	96	17	68
Cowpeas.....	19,597	16,515	2,522	560	72	11	72
Buckwheat.....	11,030	8,200	2,490	340	53	12	79

Other tables show analyses of soy-bean crops grown under various conditions.

[Field experiments with sugar cane], J. T. CRAWLEY (*Porto Rico Sugar Producers' Sta. Bul. 5* [English Ed.], pp. 5-21).—This report gives some results of fertilizer experiments with sugar cane, continuing previous work (E. S. R., 28, p. 423).

An average increase of 6.8 tons was harvested with the aid of complete fertilizers, and limed areas yielded better than unlimed. Trials showed the hole system of planting cane to be slightly superior in point of yield on a 2-year average than the furrow system. In distance planting it was noted that close (width between rows 4 ft.) planting gave larger yields, especially the first year, than wider (5 and 6 ft.) planting and reduced the cost of cultivation.

The results of cooperative tests of over 20 varieties of cane are reported. The report on seedling work covers the growing of about 2,000, and the analyses of about 300. The damage to roots, stalks, and leaves by insect pests is also noted.

Sugar-cane culture in Cuba, R. S. CUNLIFFE (*Cuba Mag.*, 3 (1912), No. 12, pp. 717-722, figs. 6).—This article describes the methods of producing sugar cane in Cuba on the 4 principal classes of soils, viz. red lands; black soils; brown, chocolate and mulatto soils; and savannah lands. The results of experiments at various places showed marked increased yields by the use of commercial fertilizers. Using 237 lbs. nitrate of soda, 95 lbs. sulphate of ammonia, 4,333 lbs. basic slag, and 114 lbs. sulphate of potash, there resulted a yield of 72,150 lbs. per acre, an increase of 59,683 lbs. over the unfertilized plat. On omitting the nitrogen the apparent increase was 60,666 lbs.; omitting the potash it was 61,534 lbs.; and omitting the phosphoric acid it was 41,816 lbs. per acre.

Seedling canes and manurial experiments, J. P. D'ALBUQUERQUE ET AL. (*Local Dept. Agr. Barbados, Seedling Canes and Manurial Expts., 1910-1912*, pp. 68).—This reports progress in sugar-cane work in continuation of that previously noted (E. S. R., 26, p. 837).

In an experiment to determine the deterioration of cut canes, 3 tons of White Transparent canes were cut from part of a field and so mixed together that 60 fairly uniform sample lots, each of 100 lbs. weight, could be drawn from the heap. Of these 60 bundles, 3 were crushed as soon as cut and the juice analyzed, 19 bundles (series A) were exposed to sun and air in the open, 19 bundles (series B) were covered with trash and left in the open, and 19 bundles (series C) were covered with trash and sprinkled with water once daily. The canes were cut on May 6 and 7, and each subsequent week day one bundle of canes from each of series A, B, and C was reweighed, crushed, and the juice analyzed.

"In series A, at the end of 3 days, besides a decrease of $8\frac{1}{2}$ per cent in weight, the purity of the juice began to diminish and the glucose ratio to increase, showing that inversion had begun. The next 3 days keeping did not show further diminution in weight, but after 4 days (from the beginning of the experiments), the diminution in purity was considerable and sufficient to affect the manufacturer's yield. These changes continued in the same direction until the seventh day, and from the seventh day onward with greater rapidity, rendering the canes of small value to the manufacturer of sugar, and of diminishing value to the manufacturer of sirup."

With series B no noteworthy change took place until after 4 days, and in series C purity was maintained until the fifth day, after which it decreased rapidly. Tabulated results are given.

Report of the agricultural work for the season between 1909-1911, J. P. D'ALBUQUERQUE and J. R. BEVELL (*Rpt. Agr. Work Barbados, 1909-1911, pp. 105*).—This report includes brief notes and results of continued work (E. S. R., 26, pp. 836, 837), mostly reported in local publications.

Sweet clover, C. C. CUNNINGHAM (*Kansas Sta. Circ. 34, pp. 6, fig. 1*).—This circular discusses the value of sweet clover in Kansas and gives directions for its production, covering the topics of preparing the seed bed, seeding, inoculating, handling sweet clover for hay, saving the seed, and sweet clover as a pasture crop and as a soil improver.

Soy beans and cotton as preparatory crops for tobacco, F. DE FREMERY (*Meded. Deli-Proefstat. Medan, 7 (1912), No. 1, pp. 57, 58*).—The results of these experiments were unfavorable. The soy bean plat produced 248,650 leaves of tobacco as compared with 266,800 on the control plat, and the cotton plat produced 95,700 leaves as against 107,350 on the control plat.

On hybrids of *Triticum* with *Ægilops* made in the year 1856, P. DE VILMORIN (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, pp. 317, 318, fig. 1*).—The author reports that he has lately discovered at Verrières some ears arising from the cross made by his grandfather in 1856 between *Triticum sativum* and *Ægilops ovata*. This cross has been made many times since, but this appears to be the only occasion on which it has succeeded. Ten hybrid plants were obtained, from the seeds of which 25 plants were raised in the year 1858. Fifteen of these plants were from *A. ovata* crossed with the wheat Blanc de Flandre. The plants varied considerably among themselves, and in the following year only 1 plant was raised, which produced no seed.

A fertile hybrid of wheat and rye, F. JESENKO (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, pp. 301-311, figs. 12*).—Plants of F_1 , F_2 , and F_3 resulted from an artificial cross between Mold-squarehead wheat and Petkus rye. It is noted that F_1 and F_2 plants seem to be perennial.

The fixity of races of wheat, P. DE VILMORIN (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps., 1911, pp. 312-316, figs. 3*).—The author draws attention to the often repeated assertion that climatic conditions may possess a modifying influence on varieties of wheat. He does not agree with this opinion, but considers that the influence of climatic conditions is limited to the suppression of unadapted forms. On finding in the laboratory of Louis de Vilmorin a collection of ears of the cultivated varieties of wheat grown at that period (1837-1855), he compared these ears with those harvested from the same varieties in 1908-1910, and found that they were identical in all respects, although separated by an interval of 50 years during which annual selection had been continued.

"This fixity is shown not only in the characters of the ear, but also in all the other characters of the plant, even that of precocity, which would appear to be most dependent on climate."

Tests of varieties of wheat, C. F. NOLL (*Pennsylvania Sta. Bul.* 125, pp. 43-56).—This bulletin includes the results of tests of about 30 varieties of wheat covering the years 1910 to 1913, inclusive. It is noted that 5 of these varieties have been in tests continually for 23 years. The yields in 1910 ranged from 15.7 to 33 bu., in 1911 from 20.3 to 39.2 bu., in 1912 from 15.7 to 26.4 bu., and in 1913 from 18.9 to 44.1 bu. per acre. The average yields of the 3 best yielding varieties for 1909 to 1913, omitting 1910, were Dawson Golden Chaff 32.3 bu., Turkish Amber 32.2 bu., and Fulcaster 29.7 bu. per acre.

Tabulated data include weights per measured bushel; average yields for periods of 3, 5, 8, 10, 11, 12, 13, 15, 16, and 22 years, respectively; and descriptions of varieties tested.

The seed control act, H. L. BOLLEY (*North Dakota Sta. Spec. Seed Bul.* 2, pp. 3-16, figs. 2).—This bulletin contains the text of the North Dakota pure seed law of 1913, with comments and notes thereon, and some instructions for collecting and sending samples of seed to the state seed commissioner.

A ready reckoner for grain buyers.—Wagonloads of various grains reduced to bushels and pounds, also wheat dockage (*Minneapolis, Minn., 1913, 2. ed., pp.* 68).—This publication presents figures showing wagonloads of various grains reduced to bushels and pounds, also wheat dockage, extending in weights up to 100,000 lbs.

HORTICULTURE.

[Report of botanical investigations], B. D. HALSTED ET AL. (*New Jersey Stas. Rpt.* 1912, pp. 349-402, pls. 26).—Inheritance studies of various crosses of sweet, pop, and flint varieties of corn (E. S. R., 28, p. 739) were continued in 1912. The transmission of texture and color in the progeny of these crosses is discussed. In one block of corn it was observed that the dark seed from the husk or cobless variety which had been pollinated with Black Mexican yielded corn growing on more or less perfect cobs. Individual grain husks were present but were sufficiently reduced in many cases to expose the grains of corn. Isolated grains of corn growing on poorly-developed ears from various crosses were found to be somewhat larger and heavier than grains from well-developed ears, but the specific gravity of these grains was only slightly increased. Attention is called to the fact that in a mixed ear of corn the sugary grains may be distinguished from the flinty grains by their more elevated position, as compared with the adjacent flinty grains. This may be noticed as soon at least as the ears are ready for the table. A study of the zigzag and irregular types of corn, such as Banana and Country Gentleman, shows that there is a normal 2-row arrangement of the unfertilized ovules and that the irregular arrangement is due to the lack of pollination of many ovules in each row. Ovule fertilization appears to take place from a midzone on the ear and to proceed toward the base and tip. The possible value of this fact in making selections for earliness and greatest vigor is pointed out. A preliminary test relative to germination of corn indicates that the slender epicotyl can accommodate itself readily to various planting depths and position of the seed in the soil.

Forty-eight F_1 crosses of peppers studied by the author are here discussed in part with reference to character transmission. Considerable variations in size and shape of peppers growing on the same plant were noted. Variation in shape within the variety appears to be due to the extent to which the placenta fills the cavity and to the more or less regular development of seed over the surface of the placenta. Size of fruit within the variety is governed largely by more or less perfect nutrition. Late maturing peppers within a variety are more nearly uniform in size than the early maturing peppers.

A brief study of several kinds of beans with reference to relation of position in pods to weight and desirability of the seed is reported on page 331, and hypocotyl studies with various plants on page 331, together with a preliminary study of shade as influencing the growth of plants in the open, and weather notes for the growing season.

Report of progress, B. H. A. GROTH (*New Jersey Stas. Rpt. 1912, pp. 404-407, pls. 6*).—A summary is given of the previous detailed report on the F_1 heredity of fruit characters in the tomato (E. S. R., 27, p. 742), together with a brief statement of work done with the F_2 and F_3 generations during 1912. The selection of many-celled and 2-celled fruits in the prairie berry (E. S. R., 28, p. 739) was continued. From the records secured at the time this report was prepared, however, high cell number does not appear to have been transmitted to the offspring from many-celled fruits selected in 1911.

Some additional data are given relative to the effect of various chemicals on plants, although no deductions are made at this time.

In the summer of 1909 some preliminary tests were made with various plants in the summer heat of the greenhouse to determine which plants might be favorable subjects for testing the permanency of environmental influence upon characters of habit. Among other plants 4 varieties of bush beans were tested. A decided change of habit attributed to excessive heat was produced in two of these varieties, both of which began to run up to a height of 6 to 8 ft. on strings like pole beans. No change in habit could be induced by the same treatment with the other two varieties during the course of three generations. Pods were taken at various heights from several plants of the varieties which had been converted into climbers, and the seeds of each pod were grown separately in the following summer under the same conditions. The seeds from the same plant, all perfectly mature, developed into plants of different heights. In the work as thus far continued, however, no direct relation has been traced between height of seed on the parent plant and maximum height in the offspring.

In previous studies of circulation in the sweet potato vine it was found that a reversed water current coming from parts of the vine fruited in favorable situations was able to keep the sweet potato leaves perfectly turgescient (E. S. R., 27, p. 731). An experiment, which is here outlined, is now under way to determine whether it is also possible to reverse the current of assimilated food materials.

A study of inheritance in garden plants, E. J. OWEN (*New Jersey Stas. Rpt. 1912, pp. 408-417, pls. 6*).—The work in 1912 was conducted along the lines noted in the previous year (E. S. R., 28, p. 740). Some general notes are given on first generation crosses of beans, together with some data on crosses and hybrids of eggplants. The yield limitation experiments with various vegetables were continued.

Some data on this work are reported for bush beans, eggplants, and tomatoes. Aside from the results previously noted (E. S. R., 27, p. 741) there appears to be a greater development of blossoms on plants which are the progeny of plants which have borne only one fruit as compared with those which have borne a full crop.

American-grown paprika pepper, T. B. YOUNG and R. H. TRUE (*U. S. Dept. Agr. Bul. 43, pp. 24, figs. 11*).—This bulletin reports the results of an experiment undertaken to determine the feasibility of growing the Hungarian paprika type of red pepper in this country. Introductory considerations deal with the history of paprika peppers, legal definition of paprika, botanical origin of paprika, characteristics of American paprika as compared with the foreign product, and commercial considerations. The cultural experiments which were carried out in South Carolina are here discussed with reference to the prevailing climatic

and soil conditions, propagation, preparation of seed bed, field planting, cultivation, fertilizers, harvesting, curing, storage, yield, financial returns, and outlook for the future.

Generally speaking it appears that there are no special cultural difficulties to be met with in growing paprika peppers in favorable locations in this country. The experimental crops grown by the Department have been harvested with a favorable margin of profit. On the other hand, until a larger market is developed for the product the planting of paprika peppers can be easily overdone.

Report of the horticulturist, M. A. BLAKE and A. J. FARLEY (*New Jersey Stas. Rpt. 1912, pp. 69-96, pls. 5*).—A brief general statement is given of progress made on various projects in 1912, together with data on the time of spraying, materials used, and cost of spraying in the Vineland peach orchards; harvesting dates of various apples at the college farm for the years 1908 to 1912, inclusive; a discussion of the nature of winter injuries to fruit trees noted on page 352; a brief account of the division's new range of greenhouses; and a description of experimental lime tests with My Maryland and Killarney roses.

An analysis of the harvesting dates of apples shows a considerable difference in the actual date of ripening of the various varieties in certain seasons and leads to the conclusion that fruit should be picked according to its actual maturity rather than at fixed dates.

In lime tests with greenhouse roses two varieties, My Maryland and Killarney, were grown in bench plats, each containing 15 sq. ft. of surface. Two plats were kept as checks; two plats each received 270 gm. of ground calcium limestone; and two plats each received 810 gm. of limestone when the plants were benched in the spring of 1910. All of the plats received the same general fertilizer treatment. Notes and data are given on the condition of the plats up to the fall of 1912, when the seventh crop of roses was gathered and the experiment discontinued. As indicated by the total yields of all the plats for the entire experiment, the unlimed plats show a smaller number of flowers of all grades (with one exception) of both My Maryland and Killarney than the plats receiving 270 gm. of limestone, and the plats receiving 810 gm. of limestone produced more flowers of all grades than the plats receiving 270 gm. of limestone. Killarney appeared to suffer much more from the increasing acidity in the soil than My Maryland. In addition to reducing the number of flowers the lack of lime appeared to reduce the length and vigor of the stems and leaves. The color of the flowers on the slightly acid plats was somewhat heightened, but when the growing shoots became very slender and weak the flowers were very light in color. From the results thus far secured it is believed to be advisable to apply annually at least 270 gm. of ground limestone to each 15 sq. ft. of bench surface, and that heavier applications may be beneficial and desirable with certain soil types, varieties, and methods of culture. Some extended studies with lime in the culture of roses are now being conducted.

Orchard spraying, W. H. ALDERMAN, N. J. GIDDINGS, and W. E. RUMSEY (*West Virginia Sta. Circ. 7, pp. 48, figs. 33*).—This circular discusses the use of spray machinery, preparation of sprays, and spray material, and briefly describes the more important diseases and insects of orchards and vineyards, including suggestions for their control.

Rational methods of pruning grapes, V. C. M. DE ZÚÑIGA (*Prog. Agr. y Pecuario, 19 (1913), Nos. 832, pp. 483-485; 833, pp. 501-504*).—A discussion of various methods of pruning grapes, with special reference to the reconstitution of phylloxera-infested vineyards, based largely on observations made in the experimental field of the enological station at Haro, Spain.

Factors governing the successful storage of California table grapes. A. V. STUBENRAUCH and C. W. MANN (*U. S. Dept. Agr. Bul. 35, pp. 31, pls. 8, figs. 7*).—This bulletin summarizes the table grapes storage investigations which have been conducted during the seasons 1906 to 1912, inclusive, special attention being given to the successful packing, storing, and marketing tests during the seasons of 1911-12 and 1912-13.

The commercial demonstrations during the two seasons, as well as the records of the Department's investigations during the whole period, show that the method of packing California table grapes with a filler of redwood sawdust and of holding them in cold storage for the holiday market is destined to form one of the successful practices of the grape industry of the State. Inasmuch as the holiday crop must compete with Spanish grapes, only fruit of the best quality should be handled in this way, those varieties which have open bunches being the most suitable for packing in redwood sawdust. The drum barrel has been found to be the most satisfactory package for grapes packed in redwood sawdust. The sawdust should be pure and unmixed with other woods and enough filling material should be used to prevent settling. The fruit should be cooled over night in the vineyard or precooled before the packages are loaded into the cars. It should be shipped under refrigeration and placed in cold storage at 32° F. immediately upon reaching its destination.

Under conditions of careful handling, packing, and storing Emperor grapes may be held in cold storage until about January 10; the Malaga variety until December 15; and the Muscat until November 15. When Almeria grapes can be grown successfully in California for commercial purposes they may be held in cold storage until about April 1.

The banana. R. U. URIBE (*Rev. Indus. y Agr. Tucumán, 3 (1912), Nos. 1, pp. 37-44; 2, pp. 71-89; 3, pp. 133-135; 4, pp. 161-181; 5, pp. 209-227; 6, pp. 261-273*).—A paper on the banana presented before the Agricultural Society of Colombia in which the author discusses the history, distribution, botany, uses, and commerce of the banana, including data on the cost of establishing plantations and the returns which may be expected.

The banana. R. DE CASTRO (*Bol. Min. Agr., Indus. e Com. [Brazil], 2 (1913), No. 4, pp. 127-140*).—An account of the banana with reference to its botany, origin, species and varieties, climatic and soil requirements, uses, commerce, and Brazilian exports.

Spraying walnut trees for blight and aphid control. R. E. SMITH, T. F. HUNT, and W. H. NIXON (*California Sta. Circ. 107, pp. 8*).—In some earlier experiments conducted by the station (E. S. R., 28, p. 349) it was found impractical to spray large walnut trees for the control of blight on account of the time and expense required by ordinary spray methods. In the experiments here described a considerable acreage of large walnut trees was sprayed, various methods and mixtures being used. It was found that the problem of spraying such large trees quickly and economically was met by the use of high-power sprayers and a special nozzle, previously noted (E. S. R., 26, p. 49), making it possible to cover the largest trees completely from the ground. The amount of material required for spraying good-sized trees thoroughly averaged from 30 to 50 gal. per tree and the average total cost of spraying per tree was about 55 cts.

The results of the spraying upon walnut blight were difficult to establish on account of the slight occurrence of the disease in the sprayed districts during the season. Well-sprayed trees remained comparatively free of aphid long after the insect had become abundant on unsprayed trees, and the improved condition, as well as the increased growth of the trees, nuts, and foliage, seemed to justify the cost of spraying, notwithstanding the fact that

the aphids finally spread from the unsprayed trees to some extent to the trees which were sprayed. The best results were secured with a mixture comprised of 5 gal. of commercial lime-sulphur solution, 25 lbs. of quicklime, and 95 gal. of water. The spraying should be done while the trees are still dormant, since the solution burns the foliage severely.

Rules and regulations of the South Carolina Crop Pest Commission governing the transportation of nursery stock.—Definition of nursery stock (*South Carolina Sta. Circ. 14, pp. 4*).—In addition to the text of the rules and regulations governing the transportation of nursery stock instructions are given for the fumigation of nursery stock originating in South Carolina, as well as the forms of certificates used by the State Crop Pest Commission.

Rules and regulations of the South Carolina Crop Pest Commission governing the transportation of bulbs, tubers, and roots (*South Carolina Sta. Circ. 17, p. 1*).—The regulations here given deal specifically with shipments from without the State of sweet potatoes, Irish potato tubers, onion bulbs, and strawberry roots.

Rules and regulations of the South Carolina Crop Pest Commission governing the transportation of seeds other than cotton (*South Carolina Sta. Circ. 18, pp. 3*).—The text of the rules and regulations is given.

FORESTRY.

Silviculture (*X. Cong. Internat. Agr. Gand, 1913, Sect. 5, pp. [218], fig. 1*).—A report of the proceedings of the silvicultural section of the Tenth International Congress of Agriculture, at Ghent, 1913, including résumés and in some cases full reports of various papers presented. See also a previous note (*E. S. R.*, 29, p. 105).

The distribution of forests in the natural regions of Switzerland, M. DECOPPET (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases, 4 (1913), No. 12, pp. 1822-1825*).—A brief descriptive account of the forest character of the Jura, the Plain, and the Alps divisions of Switzerland.

Extension of the Mexican forest flora to the plateau country of South Africa, D. E. HUTCHINS (*Quart. Jour. Forestry, 8 (1914), No. 1, pp. 16-20*).—Notes are given on the adaptation of a number of Mexican trees to the plateau country of South Africa.

The Chinese arbor vitæ (*Thuya orientalis*), C. A. SCOTT (*Kansas Sta. Circ. 33, pp. 6, figs. 3*).—A brief descriptive and cultural account of this tree, with special reference to its use in western Kansas as a windbreak and for ornamental plantings. Wherever the tree has been planted in Kansas it is making a very successful growth, having withstood the climatic conditions the past 18 or 20 years without serious injury.

Cottonwood in the Mississippi Valley, A. W. WILLIAMSON (*U. S. Dept. Agr. Bul. 24, pp. 62, pls. 6, fig. 1*).—This bulletin reports a special study made of cottonwood to determine more definitely its characteristics and the general practicability of forest management. Although the conclusions reached apply chiefly to the Mississippi Valley region, those in regard to planting are applicable wherever cottonwood can be grown.

The subject matter is discussed under the following general headings: Annual cut and present supply, character of the wood, uses, stumpage values and logging costs, range, botanical characteristics, silvical characteristics, character of stands, form and growth of individual trees, growth and yield of stands, management, returns from growing cottonwood, and planting.

An analysis of the data secured indicates that cottonwood plantings will yield at least 6 per cent on the investment. Cottonwood grows rapidly and can

be cut for pulpwood when 15 years old and for timber and veneer in 35 years. To the owner of unprotected bottom land it should appeal as a profitable tree to grow in the region, especially on the extensive areas outside the river levees.

Osier culture, H. LATIÈRE (*La Culture de l'Osier*. Paris, 1912, pp. 122, pls. 3).—A practical guide to the establishment, care, and management of osier plantations, including also information relative to the preparation and marketing of the osiers.

The rosewood of Guiana and its essential oil, E. BASSIÈRES (*Le Bois de Rose de la Guyane et son Huile Essentielle*. Paris, 1913, pp. 41, figs. 9).—A botanical study of the rosewood (*Licaria guianensis*), including an account of the distillation of rosewood oil. A note by A. Bertheau is also given on the macroscopic, histologic, and microchemic characters of the rosewood.

Rubber and rubber planting, R. H. LOCK (*Cambridge, England, 1913*, pp. XIII+245, pls. 10, figs. 22).—This is an introductory treatise on the subject, in which the author discusses the history of the use and cultivation of rubber, the botanical sources of rubber, the physiology of latex production and tapping experiments, planting operations, harvesting, factory work on the estate, the pests and diseases of *Hevea*, the cultivation of species other than *Hevea brasiliensis*, the chemistry of india rubber, and the manufacture of rubber goods.

Annual return of statistics relating to forest administration in British India, 1911-12 (*Statist. Forest Admin. Brit. India, 1911-12*, pp. 27, pl. 1).—The statistics here reported deal with alterations in forest areas, progress in forest settlements, forest surveys and forest working plans, forest protection, planting operations, yields in major and minor forest products, revenues, expenditures, etc. Statistical diagrams indicating some results of forest administration in British India are appended.

Annul report of the director of forests, N. W. JOLLY (*Ann. Rpt. Dir. Forests [Queensland]*, 1912, pp. 5).—This is a report for the calendar year 1912 relative to the administration and management of the state forests and national parks in Queensland, including data relative to forest areas, revenues, expenditures, etc.

The estimation of accretion in forest management systems, G. BAADER (*Die Veranschlagung des Zuwachses bei Waldertragsregelungen*. Inaug. Diss., Univ. Giessen, 1913, pp. 57, fig. 1).—A doctorate dissertation on this subject presented to the philosophic faculty of the University of Giessen.

A new dendrometer or timber scale, J. F. CLARK (*Forestry Quart.*, 6 (1913), No. 4, pp. 467-469, pl. 1).—The dendrometer here described and illustrated is a direct reading instrument, both as regards the height and diameter measurements of the tree.

The air-seasoning of timber, W. H. KEMPFFER (*Bul. Amer. Ry. Engin. Assoc.*, 15 (1913), No. 161, pp. 161-231, figs. 63; *abs. in Engin. Rec.*, 69 (1914), No. 2, p. 53).—In the present paper the author has collected the data on air-seasoning which has appeared in various circulars and bulletins of the Forest Service of the U. S. Department of Agriculture and has arranged them, together with data secured elsewhere, so that the results of various tests are comparable with one another.

The development and status of the wood-preserving industry, E. A. STERLING (*Sci. Amer. Sup.*, 76 (1913), No. 1958, pp. 24-27, figs. 9).—Notes and illustrations on the art as practiced in America are presented.

DISEASES OF PLANTS.

The fungi which cause plant disease, F. L. STEVENS (*New York, 1913*, pp. IX+754, figs. 449).—This book is intended as an introduction to the study of the more important cryptogamic parasites that affect economic plants in the

United States and supplements the volume by Stevens and Hall on Diseases of Economic Plants (E. S. R., 24, p. 345), in which the authors describe the gross characters of various diseases.

In the present publication technical descriptions are given of the different fungi, and keys presented whereby the student can determine the specific relationship of any parasite known to occur on economic plants in the United States. Some species have been included that have not been reported as present in this country and some nonparasitic ones are included in the keys, but no attempt has been made to give complete lists of all of them. The arrangement of the material is by orders, beginning with the slime molds, Myxomycetes, and running through the Schizomycetes and true fungi, the Eumycetes.

Extensive bibliographies are given at the end of the various groups, and a list of books and periodicals that are thought to be useful for students of plant diseases is also included.

Report on economic mycology, E. S. SALMON (*Jour. Southeast. Agr. Col. Wye, 1912, No. 21, pp. 321-404, pls. 25, figs. 8*).—Reports are given of observations on miscellaneous plant diseases, celery blight and its prevention, some spraying experiments for the control of apple scab, and notes on the American gooseberry mildew. In addition the author and assistants report on the Cytophora disease of the cherry (see p. 352), experiments with *Rhizopus nigricans* on tomatoes (see p. 351), and a new disease of apple buds (see p. 352), as well as on the lime-sulphur wash for use on gooseberries, previously noted (E. S. R., 29, p. 249).

Among the miscellaneous diseases reported upon, attention is called to the crown gall of alfalfa due to *Urophlyctis alfalfa*, a number of minor diseases of fruits, and tomato canker due to *Botrytis*, the superficial appearance of which resembles that caused by *Mycosphaerella citrullina*. In a previous publication (E. S. R., 23, p. 337) attention was called to the advantage of the presence of male hops in the control of hop mildew. Subsequent investigations have confirmed the previous conclusion that by the fertilization of the hop the growing out is hastened and the critical period when the hops are subject to mildew is shortened.

Experiments are reported on the spraying of celery for the prevention of the blight due to *Septoria petroselini apii*, from which it is concluded that three sprayings with home-made Bordeaux mixture, 4:4:50, will protect celery plants during the growing period. As the disease is liable to occur early in the season it is recommended that seedling plants be dipped in Bordeaux mixture at the time of transplanting.

For the control of apple scab, experiments were conducted on the use of Bordeaux mixture, lime sulphur, and iron sulphid as fungicides. Comparisons were also made between Bordeaux mixture (4:4:50) and the Woburn mixture, which is a greatly diluted form of Bordeaux mixture. It was found that for most varieties of apples home-made Bordeaux mixture could be successfully employed for the control of the scab, although it has proved injurious to some varieties. The Woburn Bordeaux mixture did not prove as effective as the ordinary Bordeaux mixture. Lime sulphur as a fungicide was found to check slight attacks of scab, but attention must be paid to the strength of the solution, many varieties being injured where the specific gravity was 1.01. For varieties known to be subject to injury, it is recommended that lime sulphur with a specific gravity of 1.005 be tried. The self-boiled lime sulphur and iron sulphid wash gave some very satisfactory results, and it is thought that this is worthy of further trial. The self-boiled lime sulphur and copper sulphid preparation is also believed worthy of further test.

The author reviews the present state of affairs regarding the spread of the American gooseberry mildew (*Spharotheca mors-uvæ*) in Kent. It is stated that there are 3,294 acres of infected gooseberries in Kent, as compared with 2,561 acres the previous season. This spread has been in spite of the efforts that have been carried on to control the disease, indicating that compulsory measures have no appreciable effect in clearing plantations of the disease.

A brief account is given of a disease of tomatoes due to *R. nigricans*. This trouble appeared on fruit after shipment, causing considerable loss. The fungus appears to be a facultative parasite and causes a softening and rotting of the fruit.

Report of the plant pathologist, M. T. Cook (*New Jersey Stas. Rpt. 1912, pp. 509-527*).—A summary is given of the work conducted by the department of plant pathology, which was organized under the author's direction in December, 1911. The work consists of inspection of nursery stock, orchards, and imported plants. Some studies have been made on chestnut bark disease, and investigations have been begun on peach yellows, sweet potato diseases, apple rots, and a storage rot of dahlias. The report concludes with a list of diseases reported during the year.

Report on the work of the division for plant protection, C. BRICK (*Jahrb. Hamburg. Wiss. Anst., 29 (1911), Beiheft 10, pp. 233-254*).—Brief accounts are given of diseases and animal enemies of plants reported during 1911-12 from German territory and from many other parts of the world, with more particular reference to those in portions of Germany proper, concluding with an index of injurious organisms noted in this connection.

Review of vegetable pathology (*Ann. Uff. Agr. Prov. Bologna, 18 (1911-12), pp. 194-197*).—A brief account is given of observations on injurious animals and fungi, in particular *Ophiobolus graminis* and *O. herpotrichus*, associated with stalk disease of wheat. Tabulated results are presented of reports made by several agriculturists in different localities regarding their observations on time and conditions of attack, susceptibility of varieties, effects of fertilizers, etc.

Recommendations made as to protective measures include application of fungicidal mixtures to infected stubble; rotation of crops; avoidance of excess of nitrogenous manures, also of very thick sowing; and suitable drainage.

A bibliography of mycological literature, G. LINDAU and P. SYDOW (*Thesaurus litteraturæ mycologicæ et lichenologicæ ratione habita præcipue omnium quæ adhuc scripta sunt de mycologia applicata. Leipsic, 1912, vol. 3, pt. 1, pp. 1-192; 1913, vol. 3, pt. 2, pp. 193-766+IV*).—This is in continuation of the bibliographies of mycological literature previously noted (*E. S. R., 22, p. 133*), the present volume covering the publications from 1907 to 1910, with additions and corrections to previous issues. The number of titles included in volume 3 is 12,120, and the total number of references listed in the three volumes issued to date is 41,860.

Some new or rare plant diseases, L. MONTEMARTINI (*Riv. Patol. Veg., 6 (1913), No. 7, pp. 204-210*).—The author gives brief notices of studies on some diseases and enemies of cultivated plants made or reported at the laboratory for plant pathology at Milan, including *Cladosporium cucumerinum*, damaging cucumbers; a leaf spot of Iris, ascribed to a Septoria; *Botrytis vulgaris*, parasitic on camellias; *C. pisi*, on kidney beans, etc.

A bacterium causing a disease of sugar-beet and nasturtium leaves, NELLIE A. BROWN and CLARA O. JAMIESON (*U. S. Dept. Agr., Jour. Agr. Research, 1 (1913), No. 3, pp. 189-210, pls. 3, figs. 5*).—In 1908 a bacterial disease was observed on nasturtium leaves growing near Richmond, Va., and a similar disease

on sugar-beet leaves from Garland, Utah. At the time of their recognition there is said to have been no thought of a possible relationship between the causal organisms, but subsequent studies, which have been extended to cover over four years, have shown that in essential characteristics the bacterial organisms are so nearly identical that they are considered by the authors to be the same species.

The occurrence and general appearance of the disease on the two host plants are described, and the results of numerous infection experiments are given. The morphological and cultural characters of the organism are presented in detail, and the bacterium held responsible for this disease is described as a new species, the name *Bacterium aptatum* being given it.

In addition to causing leaf spot disease of sugar beet and nasturtium, the organism was found infectious to bean leaves and pods, lettuce, pepper, and eggplant. It is considered probable that infection takes place through wounds, or by means of insect injuries, and that it may be spread by insects.

The organism belongs to the green fluorescent group and differs from *B. xanthochlorum*, which is pathogenic to the potato, and from *Pseudomonas tenuis*, which has been described as occurring in the sap of the maple tree (E. S. R., 29, p. 157). It also differs from *B. phaseoli*, although both organisms produce spotting on the leaves and pods of the bean.

The rusts of Nova Scotia, W. P. FRASER (*Proc. and Trans. Nova Scotian Inst. Sci.*, 12 (1909-10), No. 4, pp. 313-445, figs. 24).—The results are given of field and microscopic studies of the rusts of Nova Scotia, about 100 species being described. Particular attention is paid to the economic aspect of the different rusts, their heterecism, etc. A bibliography is included.

Internal æcia, F. A. WOLF (*Mycologia*, 5 (1913), No. 6, pp. 303, 304, pl. 1).—The author describes internal æcidia of *Puccinia angustata*, which, while common, are not considered the normal fructifications in this plant.

On the temporary suspension of vitality in the fruit bodies of certain Hymenomycetes, A. H. R. BULLER and A. T. CAMERON (*Proc. and Trans. Roy. Soc. Canada*, 3. ser., 6 (1912), Sect. IV, pp. 73-78).—Studies carried out since the publication by Buller of his *Researches on Fungi* (E. S. R., 22, p. 542), are said to show that dried fruit bodies of *Daldalea unicolor*, exposed in darkness to air at room temperatures, can retain their vitality for at least 7½ years, and those of *Schizophyllum commune* under similar circumstances for at least 5 years and 7 months; that the latter under similar conditions, except that they were thoroughly dried and kept at a pressure in this instance of less than 0.1 mm. of mercury, retained vitality for more than 16½ months; and that in general as regards retention of vitality when dried, exposed to ordinary air, or kept in vacuo, the fruit bodies of certain Hymenomycetes resembled in behavior the seeds of higher plants and the spores of molds.

Upon the retention of vitality by dried fruit bodies of certain Hymenomycetes, including an account of an experiment with liquid air, A. H. R. BULLER (*Brit. Mycol. Soc. Trans.*, 4 (1912), pt. 1, pp. 106-112).—Briefly reviewing the above work, the author adds an account of later experiments by himself, in which it was found that fruit bodies of *Schizophyllum commune*, after having been kept dry in exposure to air for 2 years and 8 months and subsequently dried in a vacuum and subjected to the temperature of liquid air for 3 weeks, retained their vitality. From this he concludes that there must be in this instance a temporary suspension of vitality, as claimed in case of seeds and spores studied by Becquerel (E. S. R., 21, p. 726; 23, p. 721).

Recent studies on parasitism of *Gnomonia veneta* on *Platanus*, A. TONELLI (*Riv. Agr. [Parma]*, 19 (1913), Nos. 40, pp. 626-629, fig. 1; 41, pp. 643-645).—As a result of studies and observations briefly noted, the author concludes

that *Microstroma platani*, as described by Eddelbüttel and Engelke (E. S. R., 28, p. 652), and *Glæosporium nervisequum* are stages of *G. veneta*.

Contributions on imperfect fungi, I, II, H. KLEBAHN (*Mycol. Centbl.*, 3 (1913), Nos. 2, pp. 49-66, figs. 13; 3, pp. 97-115, figs. 19).—The author concludes from the comparative study of a fungus found on dahlias that it is not identical with *Verticillium albo-atrum*. Of three fungi studied in connection with *Darlingtonia californica*, one is said to be new and is named *Glæosporium darlingtonia*, the second is not settled as to relationship, and the third is said to belong to the morphological type *Pestalozzia versicolor*.

A new nematode fungus, P. LANDNER (*Deut. Essigindus.*, 17 (1913), No. 49, pp. 465-468, pl. 1).—A brief account with illustration is given of studies by the author on a fungus invading the alimentary canal of *Anguillula aceti*, which is finally killed by the parasite. The latter is said to be closely related to *Fusarium*, but the author has designated it provisionally as *Rachisia spiralis* n. g. and sp. The possibility of combating nematodes by means of some such natural enemy is suggested.

Some important diseases of field crops in North Carolina, H. R. FULTON and J. R. WINSTON (*Bul. N. C. Dept. Agr.*, 34 (1913), No. 4, pp. 24, figs. 12).—Popular descriptions are given of the more important diseases of alfalfa, clover, corn, cotton, cowpeas, cereals, tobacco, etc.

Two new grass smuts, E. MACKINNON (*Jour. and Proc. Roy. Soc. N. S. Wales*, 46 (1912), pt. 2, pp. 201-204, pls. 4).—Descriptions are given of *Soro-sporium panici* on *Panicum flavidum* and *Ustilago panici-gracilis* on *P. gracile*.

Experiments in combating stinking smut of winter wheat, H. C. MÜLLER and O. MORGENTHAUER (*Fühling's Landw. Ztg.*, 62 (1913), No. 14, pp. 481-487).—Details are given and results tabulated of about 50 experiments with different treatments for stinking smut.

Deep planting (8 cm.) reduced somewhat the smut attack. The caustic potash and the nitric acid treatment gave favorable results and are to be further tested. It is stated that immersing the seed grain for 10 minutes in water at 55° C. has been found fully protective without lowering the percentage of germination.

Erysiphe polygoni on leaves of beet, G. NEVODOVSKII (*Viestnik Tifliss. Bot. Sada*, 1913, No. 26; *abs. in Riv. Patol. Veg.*, 6 (1913), No. 6, p. 180).—The author reports finding on beets at an experimental farm in the district of Tiflis a fungus agreeing closely, as regards morphology, with *E. polygoni*. It was suspected after further study to be a biologically specialized form of that fungus.

Foot rot, a new disease of the sweet potato, L. L. HARTER (*Phytopathology*, 3 (1913), No. 4, pp. 243-245, figs. 2; *U. S. Dept. Agr., Jour. Agr. Research*, 1 (1913), No. 3, pp. 251-274, pls. 6, fig. 1).—Attention was called in 1912 to the presence of a sweet potato disease in the Dismal Swamp region of Virginia, where as many as 95 per cent of the plants were affected.

The organism causing the disease attacks the stem, turning it black from a little below the soil line to from 3 to 5 in. above it. The first visible sign of the disease is a blackening of the lower part of the stem followed by a yellowing and dying of the lower leaves.

Successful inoculations were made with cultures of the fungus both in the greenhouse and on the Potomac Flats near Washington, D. C.

The disease was found to be due to a new species of *Plenodomus*, the name *P. destruens* being given it.

Experiments with *Rhizopus nigricans* on tomatoes, H. WORMALD (*Jour. Southeast. Agr. Col. Wye*, 1912, No. 21, pp. 381-391, pl. 1, figs. 2).—In connection with a study of the rot of tomatoes due to this fungus, the author carried on

inoculation and other experiments which showed that *R. nigricans* is a wound parasite which is capable of producing a rapid decomposition of the fleshy tissues of the tomato, even of green immature fruit. Neither the germ tubes nor the aerial hyphae were found capable of penetrating the skin of a sound tomato, but they gained entrance by way of cracks or punctures. The hyphae were much more virulent than the germ tubes produced from the spores. It was found that the development of the rot is favored by the presence of bruises, and that the fungus may also gain entrance through the removal of the stem from the fruit if the tomato is not quite ripe.

A comparison of the American brown rot fungus with *Sclerotinia fructigena* and *S. cinerea* of Europe, W. A. MATHENY (*Bot. Gaz.*, 56 (1913), No. 5, pp. 418-432, figs. 6).—Attention is called to the claim that *S. fructigena* attacks pome as well as stone fruits in America, while in Europe it is confined to pome fruits and the related species, *S. cinerea*, to stone fruit. As a contribution to our knowledge of these fungi, the author gives results of the study on some of the morphological characters of the two species and their behavior on different hosts. Pure cultures and mummified fruits containing both species were secured from Europe and the growth and other characteristics were compared with a locally produced brown rot fungus.

As a result of over 300 experiments, wide differences were noticed between *S. fructigena* of Europe and the local brown rot. *S. cinerea* when grown on plums, pears, apples, and quinces agreed in practically every instance with the disease produced by the local fungus. When grown in pure culture the European *S. fructigena* never agreed with the local form, various morphological differences between the two species being pointed out. The author states that the American brown rot of stone fruits is not identical with *S. fructigena* occurring in Europe on pome fruits, but agrees more nearly with *S. cinerea* and should be referred to that species.

A bibliography is appended.

Winter injuries to fruit trees, M. A. BLAKE and A. J. FARLEY (*New Jersey Stas. Rpt.* 1912, pp. 79-85).—The authors report the winter of 1911-12 as a very severe one on many kinds of fruit trees and attribute it to the fact that the early part of the winter was exceedingly mild, followed by unusually low temperatures in midwinter accompanied by dry, cold winds. This produced a number of kinds of injury which are classified as root injuries, twig and wood injuries, trunk splitting, bark splitting, collar injury, sun scald, and bud killing. The different forms of injury are described at considerable length and suggestions given for their prevention. These consist in better fertilization and cultivation of the trees so as to promote vigorous growth, also the use of cover crops to prevent freezing and thawing. Collar injury, it is said, may be prevented by mounding the earth about the trunks of trees before freezing weather.

A new disease of apple buds, E. S. SALMON and H. WORMALD (*Jour. Southeast. Agr. Col. Wye*, 1912, No. 21, pp. 392, 393, pls. 2, figs. 2).—For a number of years it has been observed that the flower buds of certain apple trees failed to develop and remained unopened throughout the flowering season. An examination of the diseased buds revealed the constant occurrence of a mycelium among the bud scales. In a few cases bacteria were observed in the gummy fluid, but the trouble is believed to be due to a species of *Fusarium* as yet undetermined.

The *Cytospora* disease of the cherry, H. WORMALD (*Jour. Southeast. Agr. Col. Wye*, 1912, No. 21, pp. 367-380, pls. 16, figs. 2).—The author reports the death in 1910 of a large number of young bearing cherry trees. In 1911 the disease was less serious, although considerable injury was reported.

The leaves of affected trees show a general yellowing and wilting, commencing at the tips of the shoots. The leaves begin to wither in May and the whole of the upper part of the tree is dead by October.

An examination showed the trouble to be due to *C. leucostoma*, the same fungus having previously been reported by Aderhold on the Continent as destroying cherry trees (E. S. R., 15, p. 270). Inoculation experiments were conducted to determine the parasitism of the fungus, and while this was not definitely established, the author thinks there is sufficient evidence to consider it the primary cause of the trouble.

It is said that spraying would be of little effect in controlling this disease, and the removal and burning of the affected parts is recommended.

Disease of peaches and almonds. G. ARNAUD (*Rev. Phytopath.*, 1 (1913), No. 2, pp. 24-27, figs. 2; *abs. in Riv. Patol. Veg.*, 6 (1913), No. 7, pp. 218, 219).—This is a discussion of peach-leaf curl due to *Exoascus deformans*. Directions are given for treatment with Bordeaux mixture and with lime-sulphur wash, both of which are said to give very good results as contrasted with those obtained from the use of iron sulphate and potassium permanganate.

An epidemic of fasciation and coalescence in vineyards under forced culture. P. PÉCHOUTRE (*Rev. Vit.*, 39 (1913), Nos. 1005, pp. 404-407, figs. 2; 1010, pp. 587-592, figs. 8; 1011, pp. 624-629, figs. 8; 1012, pp. 659-664, figs. 6; 1014, pp. 724-729, figs. 9; 40 (1913), Nos. 1024, pp. 135-140; 1030, pp. 324-326).—As a result of studies by the author, illustrated descriptions are given of numerous anomalies of development as regards form, size, relation, etc., exhibited by shoots, leaves, tendrils, or fruits of several varieties of grapes as recently noted in the vineyards at Nanterre, near Paris. Prominent features are torsion, coalescence, or fasciation (in some cases very complex) of shoots; deformation, dwarfing, or coherence of fruits; absence of tendrils; and deformation or union of leaf blades, petioles, etc.

It is stated that the conditions in which these anomalies occur are usually such as to contradict the view that they are due to exaggerated nutrition and exuberant vigor. Among the causes of fasciation are thought to be mechanical and insect injuries. In general it does not appear that these anomalies are hereditary or that they are transmissible by segmentation.

References to the literature of the subject are included.

Factors in mildew attack. J. CAPUS (*Rev. Vit.*, 40 (1913), No. 1027, pp. 228-232).—Reviewing the results of recent study (E. S. R., 29, p. 849), the author suggests that an explanation of some apparent inconsistencies observed in connection with mildew attack may be found in the fact that the three main contributing factors to be reckoned with, namely, the presence and number of infecting bodies, favorable atmospheric conditions, and a susceptible state of the vegetative medium, are not necessarily coincident, constant, or subject to coincident or similar variations.

Studies on roncet. L. PAVARINO (*Riv. Patol. Veg.*, 6 (1913), Nos. 6, pp. 164-170; 7, pp. 193-203).—The author gives an account of his studies during 1912 and 1913, carried out with an organism obtained from grapevines of the variety *Rupestris* du Lot affected with roncet. This was grown in pure cultures, maintaining its specific characters for more than a year. It is said to be a very active polymorphic facultative aerobic bacillus, agreeing closely in morphological and cultural characters with *Bacillus baccarinii* studied by Macchiati (E. S. R., 9, p. 924; 10, p. 224) as found in association with "mal nero" or bacterial gummosis of grapes. Two other organisms isolated are also briefly noted.

A new schizomycete of grapevines. L. MONTEMARTINI (*Riv. Patol. Veg.*, 6 (1913), No. 6, pp. 171-176).—An injurious abnormality of grapevines is de-

scribed, said to be suggestive of roncet in some respects, but to lack some features of the latter. A schizomycete is found in constant association with the trouble.

Notes on Cephaleuros, N. THOMAS (*Ann. Bot. [London]*, 27 (1913), No. 108, pp. 781-792, pl. 1).—A report is given of a study of Ceylon and Barbados specimens of Cephaleuros, one of the species of which causes a very destructive disease of tea plants in India and elsewhere. The author's investigations of the forms studied indicate that they were free from infesting fungal hyphæ, which most previous investigators have described.

The importance and control of tumors on chrysanthemum and other plants, R. LAUBERT (*Möller's Deut. Gärt. Ztg.*, 28 (1913), No. 41, pp. 486-488, figs. 4).—Giving a brief account of some infection experiments with root tumors or crown gall of *Chrysanthemum frutescens*, the author recommends destruction or radical pruning of the plants affected, and discusses briefly various other measures intended to prevent the spread of the disease.

A disease of narcissus bulbs, G. MASSEE (*Roy. Bot. Gard. Kew, Bul. Misc. Inform.*, 1913, No. 8, pp. 307-309, pl. 1).—It is stated that a disease of narcissus bulbs, which was first noted as becoming troublesome about three years ago, has become serious, some growers losing a large proportion of their bulbs. A study of the trouble has shown that it is due to *Fusarium bulbigenum*. The disease is first indicated by the presence of small, yellowish spots on the leaves. Subsequently the mycelium passes downward into the bulb involving the fleshy bulb scales, and later causes them to rot. The disease is spread through slightly diseased bulbs containing the spores, or is introduced into sound bulbs through infected soils.

Wind as a pathological factor in regard to plants, F. J. MEYER (*Naturw. Wehnschr.*, 28 (1913), No. 38, pp. 599-606, figs. 5).—Illustrations and descriptions are given of some effects of wind in destroying, deforming, or stunting trees, or in affecting otherwise their normal development.

A bibliography is appended.

Polyporus dryadeus, a root parasite of the oak, W. H. LONG (*U. S. Dept. Agr., Jour. Agr. Research*, 1 (1913), No. 3, pp. 239-250, pls. 2; *Phytopathology*, 3 (1913), No. 6, pp. 285-287).—Attention is called to the rot attributed in Europe to *P. dryadeus*. The author states that a study of materials indicates that the fungus is undoubtedly identical with the heart-rotting fungus known in America as *P. dryophilus* and that the rot and sporophore described by Hartig do not belong to *P. dryadeus* but to *P. dryophilus*.

Extensive field studies made in the forests of Arkansas, eastern Texas, Oklahoma, Maryland, and Virginia showed that the fungus *P. dryadeus* is common on many species of oak, where it produces a white sap rot and a heart rot in the roots. The growth of the fungus seems to be limited to the underground parts of the tree. In most cases only old or much suppressed trees were found attacked by the fungus. The disease does not seem to spread to adjacent trees. It is believed to be widely distributed both in America and in Europe, probably being found in these countries throughout the range of the oak trees.

A short bibliography is appended.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

[Game and fur-bearing animals in Indiana], G. W. MILES (*Bien. Rpt. Comr. Fisheries and Game, Ind.*, 1911-12, pp. 229-267, pls. 15).—The papers here presented relate to attempts to establish European game birds in Indiana (pp. 234-236) with an illustrated account of H. A. Link (pp. 237-267) of The Fur Bearing Animals of an Indiana Farm.

Gaertner group bacilli in rats and mice, W. G. SAVAGE and W. J. READ (*Jour. Hyg. [Cambridge]*, 13 (1913), No. 3, pp. 343-352).—Forty-one rats were examined for the presence of Gaertner group bacilli. Bacilli identical with *Bacillus enteritidis* were isolated from 5 rats in each case from the spleen (in 2 from liver also), but no members of this group were isolated from the intestinal contents.

"Several of the rat sera were capable of agglutinating Gaertner group bacilli in high dilution. These facts point to the view that old infection with Gaertner group bacilli had taken place. The general result of the investigation is in favor of the view that while rats are liable to be infected with Gaertner group bacilli and to be ill in consequence these bacilli are not natural intestinal inhabitants. If this be accepted, it may be stated that this group of bacilli are not natural intestinal inhabitants of any known animal species.

"Rats infected with Gaertner group bacilli may serve as a means of infecting meat with these bacilli and may possibly in this way be a cause of meat poisoning outbreaks."

Report of the entomologist, T. J. HEADLEE (*New Jersey Stas. Rpt. 1912*, pp. 421-454, pls. 3, figs. 9).—This report consists of a number of articles by the author and others. An illustrated description of the new entomological building is given by R. S. Patterson (p. 422). A discussion of the occurrence of the more important insect pests during the year (pp. 423-443) and a preliminary report on greenhouse insecticides (pp. 444-450) are by H. B. Weiss. A brief report of work with the peach borer and plum curculio is given by R. S. Patterson (pp. 451-454).

In order to determine the value of various preparations sold as greenhouse insecticides, they were applied to palms infested chiefly by scales. *Kentia forsteriana*, *K. belmoreana*, *Latania rubra*, and *Pandanus pacificus* were all infested by *Chrysomphalus dictyospermi*, and *P. veitchii* by *C. aonidium*. The results are presented in tabular form. *Livistonia rotundifolia* and *Areca verschaffeltii* seemed to be the only plants which will stand Scalecide 1:20 without injury. "Scaline at 1:25 and 1:30 gives promise of being better than Scalecide, but further experimentation is necessary. Using hydrocyanic acid gas, the effects on the Kentias were discouraging. It failed to kill entirely when used at $\frac{1}{16}$ oz. to 100 cu. ft., and at $\frac{3}{32}$ oz. to 100 cu. ft. the plants were injured. However, *P. pacificus*, *L. rotundifolia*, and *P. veitchii* stood $\frac{1}{4}$ oz. to 100 cu. ft. with no injury and complete killing of the insects."

Insecticides experimented with to determine their value in destroying radish root maggots (*Phorbia fusciceps*), including corrosive sublimate, Sulfocide, and potassium cyanid gave negative results, as fully two-thirds of the radishes were infested and one-third were entirely unsalable.

Report of the entomologist, D. L. VAN DINE (*Porto Rico Sugar Producers' Sta. Bul. 5 [English Ed.]*, pp. 25-46).—This annual report of the entomological work for the year, which was mainly with May beetles and their white grubs, is in continuation of those previously noted (*E. S. R.*, 29, p. 52). The report includes a list of the species known to attack sugar cane in Porto Rico, together with their associates, parasites, and other natural enemies, and a list of the references to the entomology of sugar cane in Porto Rico.

A feature of the work of the year was the discovery of the occurrence of a weevil root borer of sugar cane in injurious numbers in several localities. Adults that were reared from grubs taken from the roots of cane have been identified as *Diaprepes spengleri*, which under the name *Exophthalmus spengleri* was recorded by Barrett in 1903 as an enemy of citrus stock and the following year as being abundant in orange orchards and common in coffee

plantations, and has since been reported by Hendricksen and by Tower as a pest in orange groves. The injury caused by this root borer is serious in restricted areas. The author observed the adult weevil feeding upon the leaves of sugar cane and in several instances upon the leaves of *Spondias lutea*, used as fence posts about sugar cane fields.

The larvæ of a rhinoceros beetle, the identity of which has not yet been determined but is thought to be *Strategus titanus*, recorded from St. Croix (E. S. R., 28, p. 256) and Jamaica, where it is a pest of sugar cane, and which was also recorded from Porto Rico by Stahl in 1882, have been found breeding at the roots of cane on the southern coast of the island and are a source of injury.

Several species of entomogenous fungi were found attacking some of the injurious sugar cane insects. The Hawaiian fungus *Metarrhizium anisopliæ* was found to attack both the adult May beetles and their white grubs, also the larvæ of the rhinoceros beetle. Observations indicate that this fungus was established on the island naturally previous to its intentional introduction from Hawaii.

Insects injurious to sugar cane in Porto Rico and their natural enemies, D. L. VAN DINE (*Jour. Bd. Agr. Brit. Guiana*, 6 (1913), No. 4, pp. 199-203).—A list of some 21 pests and their natural enemies.

Report on a trip to Demerara, Trinidad, and Barbados during the winter of 1913, G. N. WOLCOTT (*Porto Rico Sugar Producers' Sta. Bul.* 5 [English Ed.], pp. 47-68).—In reporting observations made during his trip the author first discusses cane cultivation on the several islands visited. This is followed by a detailed report upon sugar cane insects in each island, and their parasites and predators, and insect pests of cane growing in the islands whose introduction into Porto Rico should be prevented.

Report on a trip to Demerara, Trinidad, and Barbados during the winter of 1913, G. N. WOLCOTT (*Jour. Econ. Ent.*, 6 (1913), No. 6, pp. 443-457).—The data here presented are noted above.

Insect pests at St. Croix (*Agr. News [Barbados]*, 12 (1913), Nos. 302, p. 378; 303, p. 394).—This account from the report of the director of the department of agriculture at St. Croix for the year ended June 30, 1913, deals chiefly with the insect pests of sugar cane and cotton.

The most important pest of sugar cane is the rhinoceros beetle *Strategus titanus*. The pink mealy bug is of frequent occurrence and a source of considerable damage to sugar cane, especially to the young canes. The moth borer was also a serious sugar cane pest. The weevil borer (*Sphenophorus sericeus*) occurs in the cane fields each season; a large longicorn beetle (*Lagochirus araneiformis*) has been discovered boring in canes at the experiment station.

The cotton pests at St. Croix are said to be largely the same as those occurring in the adjoining islands of the Leeward group, namely, the cotton worm (*Alabama argillacea*); the cotton bollworm; several other lepidopterans, the caterpillars of which attack the flower buds and bolls, namely, *Prodenia ornithogalli*, *P. latifascia*, and two undetermined species; the green leaf bug (*Nezara viridula*); the leaf footed plant bug (*Phytoglossus gonandra*); the cotton stainer (*Dysdercus andreae*); and the leaf blister mite (*Eriophyes gossypii*).

The scarabee (*Cryptorhynchus batatae*) attacks potatoes in all parts of the island; Indian corn is seriously attacked by the corn ear worm and the so-called corn fly or leafhopper (*Dicranotropis maidis*).

New insect enemies of carnations in the vicinity of Antibes, E. MOLINAS (*Jour. Agr. Prat.*, n. ser., 25 (1913), Nos. 21, pp. 654-657, figs. 3; 23, pp. 717, 718, figs. 2; 26 (1913), No. 27, pp. 23, 24).—Three new pests, a microlepidopteran (*Tortrix pronubana*), a noctuid (*Brotolomia meticulosa*), and a hemipteran (*Aphrophora spumaria*) are said to have been the source of injury to carna-

tions. Accounts are given of the first two mentioned and means for combating them.

Rules and regulations of the South Carolina Crop Pest Commission governing the transportation of materials from cotton boll weevil territory (*South Carolina Sta. Circ. 16*, pp. 3).—The text of these rules and regulations is given.

Rules and regulations of the South Carolina Crop Pest Commission governing the transportation of cotton seed originating outside of boll weevil infested territory (*South Carolina Sta. Circ. 15*, pp. 4).—The text of these rules and regulations is given.

Notes on the negative geotropism of *Corythuca ciliata*, *Adalia bipunctata*, *Coccinella 9-notata*, and *Megilla fuscilabris*, II. B. WEISS (*Jour. Econ. Ent.*, 6 (1913), No. 5, pp. 407-409).—The author concludes that "other factors being equal, sunlight and possibly high temperatures shorten the distance covered during a geotropic response and also the time during which the beetle responds to such stimuli, thereby giving the beetle a greater chance to find food. Sunlight does not, however, influence the direction of locomotion or the negative geotropic position assumed by the beetle."

A rhododendron borer (*Corthylus punctatissimus*), E. P. FELT (*Jour. Econ. Ent.*, 6 (1913), No. 5, p. 427).—This ambrosia beetle was found working in rhododendron stems in New York City, where it seems to be a rather serious, though distinctly local, pest. It can be controlled by cutting out and burning the affected stems.

Notes on Oregon Coccinellidæ, H. E. EWING (*Jour. Econ. Ent.*, 6 (1913), No. 5, pp. 404-407).—The author discusses the relative economic importance of different species of lady beetles found in Oregon, their migration and hibernation habits, and the emergence of adults in spring, and presents miscellaneous notes and observations.

The presence and percentage of cantharidin in *Epicauta adspersa*, J. SCHRÖDER (*Rev. Inst. Agron. Montevideo*, 1913, No. 12, pp. 9-14).—Analyses made of *E. adspersa* collected in Uruguay, by Siegfried's method, show the presence of 0.77 per cent of cantharidin in the fresh material and 1.72 per cent after drying at 45° C.

A brief review of our species of *Magdalis*, with notes and descriptions of other North American Rhynchophora, H. C. FALL (*Trans. Amer. Ent. Soc.*, 39 (1913), No. 1, pp. 23-72).—This paper includes a synoptic table for the separation of 15 species of the genus *Magdalis*, of which 6 species are described as new. Biological notes relating particularly to their host plants are included.

Descriptions of and notes on weevils belonging to a number of other genera, namely, *Trichomagdalis* n. g., *Lixus*, *Dinocleus*, *Phyllotrox*, *Eulyptus*, *Anthonomus*, *Epimechus*, *Orchestes*, *Conotrachelus*, *Acallodes*, *Auletes*, *Baris*, and *Pycnobaris*, follows.

The present status of control measures for the rhinoceros beetle (*Oryctes rhinoceros*) in Samoa, K. FRIEDERICHs (*Tropenpflanzer*, 17 (1913), Nos. 10, pp. 538-556, figs. 4; 11, pp. 603-619, figs. 9; 12, pp. 660-675, figs. 8).—A discussion of the rhinoceros beetle, an account of which by Jepson has previously been noted (*E. S. R.*, 28, p. 561). The subject is dealt with under the headings of direct and indirect measures, natural enemies being discussed under the latter.

An unusual type of injury due to a thrips, J. R. WATSON (*Jour. Econ. Ent.*, 6 (1913), No. 5, pp. 413, 414, pl. 1).—The author reports observations of a new thrips (*Cryptothrips floridensis*), which is a camphor tree pest at Satsuma, Fla. The larvæ attack the buds, in some instances killing them outright. Later they attack the younger twigs—feeding in groups—causing the bark to dry up and crack.

"For the adults a solution composed of $\frac{1}{2}$ gal. whale oil soap, $\frac{1}{2}$ gal. of commercial lime-sulphur, and $\frac{1}{2}$ lb. of blackleaf 40 to 50 gal. of water is now in use. This has proved quite efficient."

Note on the occurrence of the felted beech coccus, *Cryptococcus fagi*, in Nova Scotia, C. G. HEWITT (*Canad. Ent.*, 46 (1914), No. 1, pp. 15, 16).—*C. fagi*, a coccid which seriously affects the beech in England and Europe, is said to be well distributed in the Halifax district, Nova Scotia, occurring on ornamental and forest beeches.

The gasoline torch treatment of date palm scales, R. H. FORBES (*Jour. Econ. Ent.*, 6 (1913), No. 5, pp. 415, 416).—The gasoline blast torch has been found to be very effective as it penetrates inward and downward into the spaces between the leaf bases, thus reaching and exterminating *Parlatoria blanchardi*, one of two important date scales occurring in Arizona. *Phenico-coccus marlatti* is not reached by this treatment, but by cutting the old leaf stubs of the palm clear down to the bole of the tree, thus largely removing the infestations of this scale, and then thoroughly burning the exposed bole of the tree with the gasoline torch it may be entirely removed.

Some recent studies of the grape phylloxera, P. MARCHAL and J. FEYTAUD (*Rev. Vit.*, 40 (1913), Nos. 1020, pp. 5-11, pl. 1, figs. 6; 1021, pp. 33-41, figs. 3; 1023, pp. 104-110, figs. 2).—A review of recent investigations of the biology of *Phylloxera vastatrix*.

The false tarnished plant bug as a pear pest, P. J. PARROTT and H. E. HODGKISS (*New York State Sta. Bul.* 368, pp. 363-384, pls. 8, figs. 11).—Recent investigations have shown that the injuries to pears, characterized by the cracking open of the skin in small spots and the formation of protruding granular areas, the seriously injured pears usually being deformed and undersized, are caused by *Lygus invitus*, which the authors have termed the false tarnished plant bug because of its resemblance to *L. pratensis*. The damage is done by the nymphs which attack both the fruit and foliage. They show a preference at first for the tender leaves, attacking those that are unrolled along the margins of the fold or those that are expanding at the apices or along the edges of the unfolded margins. The tissues about the points of injury turn black, and if the punctures are numerous, more or less extensive areas along the margins of a leaf shrivel and become dry. The dead portions later become detached from the healthy tissues by the whipping of the wind, which may cause the affected foliage, usually on the growing shoots, to assume a ragged or frayed appearance.

"The principal injury by this insect is the piercing of the young pears which later become much scarred and misshapen. The young nymph thrusts its proboscis deeply into the substance of the tiny pear and on withdrawing it sap flows from the puncture. The sap dries, leaving a blackish spot. One nymph may make many wounds, and the perforations, which at first seem small and inconsequential, result in a disfiguration which becomes increasingly conspicuous as the young pear develops in size. When the fruits have become as large as filberts they are conspicuously marked with hard, granular spots of irregular shapes, varying in size from a pin prick to $\frac{1}{4}$ in. Wherever they occur the epidermis is ruptured and uplifted while the exposed surfaces are mealy like and of a light yellow color, contrasting strongly with the healthy tissues. By cutting into the fruit one will find hard, flinty areas which form cores in the flesh. When these are numerous the knife cuts with difficulty through them. Similar injuries may occur on the stems. Occasionally a number of the diseased spots may coalesce, producing a large crack which extends deeply into the flesh of the pear. Severely injured fruit, besides being badly deformed, may also be stunted in its growth, which may seriously affect its market value."

The Bartlett pear is especially subject to attack; the Angouleme has frequently suffered to an equal degree, and the Clairegeau, Seckel, and Kieffer are susceptible to injury. Thus it would appear that none of the leading sorts are likely to be exempt from injury. The pest has been very destructive for many years in an orchard at Lockport, where in 1908 it was estimated that 75 per cent of the pears had been attacked, of which only 25 per cent would when mature prove saleable.

The work of this pest on the grape is less conspicuous than on the pear, its injury to the foliage being quite similar to that on pears and its attacks of the blossom clusters causing the most serious injury. Though it has not been observed to attack peaches under natural conditions it readily attacked them under confinement.

The authors present technical descriptions of its several stages, there being 5 nymphal instars. "The nymphs of the first two instars are pale, fragile creatures which are very active and subsist largely on the juices of the tender foliage. In the older stages they are more sedentary and attack both leaves and fruits. The habit of feeding in rather restricted areas is responsible for serious injuries to young pears. The destructive activities of the insects occur during the period coincidental with the conclusion of pollination and the formation of the fruit.

"Tests during the past 3 years have demonstrated that spraying as the blossoms drop largely prevents the deformation of the young pears. The spraying mixture that is recommended is $\frac{3}{4}$ pint of tobacco extract (400 per cent nicotin) to 100 gal. of water to which are added 3 lbs. of dissolved soap. Thorough applications, using liberal quantities of the spray, are essential to accomplish the desired purpose. . . . As injury occurs within a short period after fruit has set the orchardist should examine his trees carefully, commencing with the dropping of the petals, to note conditions with respect to the nymphs."

Brief mention is also made of *Lygidea mendax*, *Campylomma verbasci*, *Paracalocoris colon*, and *P. scrupeus* as associated insects.

A pear-deforming plant bug, F. H. HALL (*New York State Sta. Bul.* 368, popular ed., pp. 3-8, figs. 10).—A popular edition of the above.

A new insect pest of coconut palms in British Guiana, G. E. BODKIN (*Jour. Bd. Agr. Brit. Guiana*, 7 (1913), No. 2, pp. 87-90).—An account of *Castnia daedalus*, a lepidopteran which burrows between the trunk of the coconut palm and the broad and thickened bases of the branches. In old trees the signs of attack are said to be quite characteristic, consisting of deep, irregular, longitudinal scars or furrows running up the trunk of the palm in continuous lines. This borer is extremely abundant in British Guiana in coconut palms along the west bank of the Demerara River and the east bank of the Berbice River.

Control measures consist in the removal of all the lower branches by cutting away at the base and securing the worm. It is stated that as many as 19 specimens of *C. daedalus* in its several stages of development have been taken from a single palm.

A brood study of the codling moth, T. J. HEADLEE (*Jour. Econ. Ent.*, 6 (1913), No. 5, pp. 389-395, figs. 4).—This is a report of cage studies made in Kansas in 1912 of broods of the codling moth.

"In 1912 in the course of the outdoor tree cage studies at Manhattan, 3 distinct and successive appearances of each of the codling moth's stages, except of larval emergence, were determined. The third emergence of codling moth larvæ would come during late September and October. In view of the fact that larvæ emerging during late September and October in 1911 pupated and produced moths in the spring of 1912, it seems entirely likely that these larvæ

of the third brood matured, emerged, hibernated, pupated, and produced moths in the spring of 1913. The fact that only 48 per cent of the larvæ of the second brood pupated this season shows that the third brood is only partial."

The *Calliephialtes* parasite of the codling moth, R. A. CUSHMAN (*U. S. Dept. Agr., Jour. Agr. Research*, 1 (1913), No. 3, pp. 211-238, pl. 1, figs. 15).—This is a detailed report of studies of a species of *Calliephialtes*, the identity of which is still open to doubt, and in lieu of which technical descriptions of *C. messor*, characterized by Gravenhorst in 1821; *C. comstockii* described by Cresson in 1880; and *C. pusio* by Walsh in 1873, are reproduced. This parasite was imported into California in 1904 by G. Compere, who found it attacking the codling moth in Spain.

The author's studies, commenced in the spring of 1911, were conducted at Vienna, Va. He first describes the methods and apparatus used in its propagation. In a detailed account of biological studies much of the data are presented in elaborate tables. Oviposition began in cages about 9 days after the emergence of the female, the full-grown larva in its cocoon being the stage of the host selected. The eggs, only one of which is deposited at a time, are placed at almost any point in the cocoon, not necessarily on the host larva, and normally only one parasite develops on a single host. The results of cage experiments indicate that the total individual oviposition was in the neighborhood of 75 eggs, the average daily oviposition being about 2 eggs. The incubation period of 825 eggs varied from 1 to 7 days, or inversely with the average mean temperature. The larva begins feeding very shortly after hatching and may attack its host at almost any point, although it is more likely to attack the dorsum or sides than the venter. The feeding period, from the hatching of the egg to the beginning of the cocoon varied, in a total of 579 cases observed, from $3\frac{1}{2}$ to $18\frac{1}{2}$ days, with an average of about $7\frac{1}{4}$ days. A considerable portion of the larval life is passed in the cocoon, the maximum period in which, as determined for 116 female larvæ and 404 male larvæ, requiring 24 days and $36\frac{1}{2}$ days, respectively. The actual minimum and maximum larval periods for females were 12 and 27 days, respectively, and for males $7\frac{1}{2}$ and 51 days, respectively. The pupal periods, which were determined for 109 females and 366 males, varied from 6 days for males in July and August to 13 days for females in June. The period in the cocoon includes a part of the larval life, all of the pupal period, and a small portion of the adult life. The duration of this period was determined for 111 females and 396 males. The total possible minimum period is computed for females as 14.5 days and for males 10.5 days, and the total possible maximum period for females 39 days and for males 50 days. The actual minimum and maximum for females were 15.5 and 37.5 days, respectively, and for males 11.5 and 36 days. Transformation from the pupa to the adult within the cocoon takes place 1 or 2 days before the emergence of the adult, depending largely on the difficulty encountered by the insect in biting its way by the remains of the host and through the 2 cocoons. The average longevity of 132 females was 51 days. The females frequently fed on the juices of the codling moth larvæ, on one occasion a female having been observed to kill and partially eat a larva that had left its cocoon and was at large in the cage. The total developmental period from oviposition to emergence was determined for 112 females and 399 males, and for females it ranged from 23.5 days to 44.5 days and for males from 18 to 44 days.

No definite experiments were conducted in the experimental control of the development but Newman records having kept immature specimens of *C. messor* in cold storage for a period of 14 months, after which they emerged without having suffered in the least. As regards seasonal history the author reports that the first females emerged from hibernation in the spring of 1912 on May 3

and the last on May 15. The first egg was deposited on May 13, 10 days after the first emergence. From the earliest female progeny 3 complete generations were reared and from the latest group 2 generations, the total time consumed by the 3 generations being only 1 day longer than that consumed by the 2. With the hibernating brood this gives a maximum of 4 generations in the year and a minimum of 3 generations. Development was found to cease at about 50° F. although oviposition was frequently carried on actively at that temperature. This parasite hibernates as a full-grown larva in its cocoon, in which stage it is capable of withstanding a very low temperature. The mortality among hibernating larvæ during the winter of 1911-12 was very slight, if not nil, in spite of the fact that a temperature of -6° was recorded in the insectary.

In a study of the alternate hosts the author found that a *Enarmonia* larva available was parasitized within 2 days, a diminutive male emerging from the cocoon 22 days later. The larvæ of neither *Euzophora semifuneralis* nor *Gnorimoschma gallaesolidaginis* were parasitized, although the former were left in the cage for several weeks. A codling moth larva containing the internally parasitic larvæ of *Ascogaster carpocapsæ* was readily attacked and parasitized by this *Calliephialtes* and this always resulted in the death of the earlier parasite and the production of diminutive adult *Calliephialtes*.

An annotated list of 19 references to literature is appended.

On the pupal instar of the fruit tree leaf roller (*Archips argyrospila*). W. M. DAVIDSON (*Jour. Econ. Ent.*, 6 (1913), No. 5, pp. 396-398).—Records of the observations made at San Jose, Cal., in 1911 of the date of pupation and the date of adult emergence of 77 individuals of this pest are presented in tabular form.

Cellia pulcherrima, with some new facts as to the date of appearance and wintering of *Anopheles bifurcatus* in Turkestan, J. B. VASSILIEV (*Trudy Bûro Ent. [St. Petersburg]*, 10 (1913), No. 6, pp. 20, pl. 1, figs. 11; abs. in *Rev. Appl. Ent.*, 1 (1913), Ser. B, No. 11, pp. 193-196).—This paper includes biological studies of the anopheline mosquito *C. pulcherrima*, the most characteristic representative of the malaria-bearing species in Turkestan.

Report on the mosquito work for 1912, T. J. HEADLEE (*New Jersey Stat. Rpt. 1912*, pp. 457-506, pl. 1).—This consists of a brief history of the work by the author (pp. 457-461); reports upon salt marsh work (pp. 461-489) and upon the county mosquito extermination commissions (pp. 490-493), by H. H. Brehme; upon larvicides and calcium carbide (pp. 493-496), by H. B. Weiss; and upon mosquitoes of the season and miscellaneous inspections (pp. 497-506), by H. H. Brehme. The text of an act for the establishment of county mosquito extermination commissions is included.

The life history of *Dermatobia hominis*, F. KNAB (*Amer. Jour. Trop. Diseases and Prev. Med.*, 1 (1913), No. 6, pp. 464-468).—This is a critical discussion of recent papers relating to the manner in which the larva of this fly gains entrance to its host. It appears that the eggs of this fly are in some way attached in clusters of about 16 in number to the basal third of the abdomen of mosquitoes of the genus *Janthinosoma*. The eggs of the *Dermatobia* hatch and the larvæ find their way into the host while the mosquito is sucking blood.

The life history of the Mediterranean fruit fly (*Ceratitis capitata*) with a list of fruits attacked in the Hawaiian Islands, H. H. P. SEVERIN (*Jour. Econ. Ent.*, 6 (1913), No. 5, pp. 399-403, pls. 2).—This is supplementary to the papers previously noted (E. S. R., 29, pp. 54, 257).

Some parasites of *Simulium* larvæ and their possible economic value, E. H. STRICKLAND (*Canad. Ent.*, 45 (1913), No. 12, pp. 405-413, figs. 4).—In his discussion of this subject, accounts relating to which have been previously

noted (E. S. R., 29, p. 856), the author includes a brief résumé of the peculiarities in structure and habits of the larvæ. In the vicinity of Boston during 1911 the spring brood of *Simulium* was parasitized by various species of *Myxosporidia* up to as high as 80 per cent mortality, and by *Mermis* sp. up to 25 per cent mortality. The fall brood was parasitized by *Glugea* spp. up to 10 per cent mortality, and by *Gregarine* sp. up to 50 per cent mortality.

The rôle of ichneumon females in the control of the sex of their descendants, I. CHEWYREUV (*Compt. Rend. Soc. Biol. [Paris]*, 74 (1913), No. 12, pp. 695-699; *abs. in Jour. Roy. Micros. Soc. [London]*, 1913, No. 4, p. 385).—The author's observations of the oviposition of *Pimpla instigator* and other species in the pupæ of species of *Sphinx*, *Pieris*, etc., representing large and small pupæ, indicate that the female parasite adjusts the kind of egg to the nutritive conditions available. In the experiments conducted female parasites emerged from the large pupæ and males from the small pupæ.

The second paper (pp. 698, 699) relates to parthenogenesis. While the fecundated females lay eggs that develop into both sexes, those laid by virgin females produce males only. In the case of the fecundated females, the eggs which produce males are unfertilized eggs, and these are laid in smaller pupæ if any choice is afforded.

A fresh feature of the large larch sawfly outbreak in the Lake District, J. MANGAN (*Nature [London]*, 91 (1913), No. 2282, pp. 530, 531).—The author reports that during 1912 *Mesoleius tenthredinis*, which has frequently parasitized as high as 70 per cent of the larvæ of *Nematus erichsonii*, parasitized scarcely 2 per cent in the Lake District. On the other hand some 25 per cent of the cocoons yielded specimens of another ichneumon which has hitherto played quite an insignificant part as a parasite of this sawfly. The tachinid *Zenillia pexops* emerged from approximately 24 per cent of the cocoons.

A further parasite of the large larch sawfly, R. A. WARDLE (*Nature [London]*, 92 (1913), No. 2298, p. 320).—It is stated that the ichneumon parasite recorded above has been identified as *Hyperablus albopictus* (= *Mesoleius transfuga*).

The red spider on jute (*Tetranychus bioculatus*), C. S. MISRA (*Agr. Jour. India*, 8 (1913), No. 4, pp. 309-316, pl. 1).—Since 1909 when the attack of jute by this red spider was observed for the first time, it has been the source of considerable injury to this plant in India. "Besides jute, the red spider is also found on cotton, castor, mulberry, orange, indigo, *Trumpheta neglecta*, *Urena lobata*, *Hibiscus ficulneus*, *H. penduriformis*, and *H. abelmoscus*. In the case of castor, when the crop is badly infested the leaves turn pale yellow and become unfit to be served to eri worms (*Attacus ricini*)."

Its life cycle is said to be passed in 8 or 9 days. As a remedial measure, spraying with a mixture consisting of crude oil emulsion $\frac{1}{2}$ pint, flowers of sulphur 2 oz., and water 4 gal. is recommended.

New species of mites, H. E. HODGKISS (*Jour. Econ. Ent.*, 6 (1913), No. 5, pp. 420-424).—One species of *Anthocoptes*, 9 species of *Eriophyes*, 2 species of *Oxypleurites*, and 8 species of *Phyllocoptes* are described as new to science.

FOODS—HUMAN NUTRITION.

The phosphorus content of wheat and of wheat flour; and its relation to the baking qualities of the flour, H. L. WHITE and R. F. BEARD (*North Dakota Sta. Bul.* 106, pp. 59-64).—Hard wheat patent flours, hard wheat straight flours, and durum patent flours were used in these investigations, and determinations were made of the total, organic, inorganic, and water-soluble phosphorus.

According to the authors' summary, "a marked variation in all these divisions of the phosphorus content was found. A comparison of phosphorus content with loaf volume was made. Summarizing the data obtained, it is found in general that the larger loaves contain less of all divisions of phosphorus than the smaller loaves. Calculated on the basis of total phosphorus equal to 100 per cent, it is found that the larger loaves contain a higher percentage of organic phosphorus than the smaller loaves, the averages of two groups being 93.5 per cent for the larger and 87.3 per cent for the smaller."

The influence of bran extracts on the baking qualities of flour, H. L. WHITE (*North Dakota Sta. Bul.* 106, pp. 47-58, figs. 3; *Jour. Indus. and Engin. Chem.*, 5 (1913), No. 12, pp. 990-993, figs. 3).—Acid extract of bran, water extract, acid extract neutralized, and dilute hydrochloric acid were used to replace part of the water required for making dough in 2 series of baking tests with flour from Bluestem, durum, and Velvet Chaff wheat.

It was found, in general, that the acid extract produced loaves showing from 6 to 20 per cent increase in volume, with a better color and texture than were obtained in the check test or in the tests in which the other extracts were used. In the test with water extract, the loaves were somewhat larger in the check test, while with dilute acid a loaf of decreased volume and very poor texture was obtained.

Analysis of the acid and the water extract of bran showed 0.464 and 0.163 gm. P_2O_5 , respectively, per 100 cc. extract.

"It is thought the presence of both acid and soluble salts makes the gluten more coherent. In general, the better the flour, that is, the stronger the gluten, the more marked is the improvement by use of acid extract; but all samples of flour show greater or lesser improvement. The inner portions of the loaves of bread made with acid extract show no greater amount of water-soluble acid reacting material than the average of homemade or bakers' bread."

Experiments undertaken to show whether or not acid extract had a stimulating effect on yeast were not convincing.

The structure of the soy bean, T. E. WALLIS (*Pharm. Jour. [London]*, 4, ser., 37 (1913), No. 2597, pp. 120-123, figs. 7).—Histological data regarding the ground and the unground soy bean are reported. The author notes that soy bean meal is occasionally adulterated with cotton-seed meal, ground dried grains, sand, rice starch, and unidentified material.

Sections of the black and brown soy beans show "that the color is due to pigment in the cell walls of the epidermal cells. The walls are colored deep crimson in the case of the black beans and pale yellow-brown in the brown beans. The structure of all parts of the seeds otherwise exactly resembles that of the ordinary yellow beans."

Philippine fruits—their composition and characteristics, D. S. PRATT and J. I. DEL ROSARIO (*Philippine Jour. Sci., Sect. A*, 8 (1913), No. 1, pp. 59-80, pls. 16).—Data are given regarding the appearance, character, and uses of a large number of fruits, and analyses are reported. Among others, the list includes the mango, pineapple, pomelo, papaya, melon, tamarinds (ripe and green), mangosteen, guava, chico mamey, durian, and breadfruit.

A study of the composition of cider vinegars made by the generator process, L. M. TOLMAN and E. H. GOODNOW (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 11, pp. 928-933, figs. 3).—The conclusions drawn from the experimental data reported follow:

"Vinegar manufactured by the generator process is uniform in its composition, as uniform as the cider from which it is prepared—in which respect it differs materially from the vinegars manufactured by the old barrel process.

With the exception of the conversion of the alcohol into acetic acid there is but little change in the composition of the cider as it is being converted into vinegar. The most marked difference, other than the oxidation of the alcohol into acid, is the elimination, or perhaps, destruction of the fixed acids. Here there appears to be an almost constant loss during acetification. On the other hand, there is a considerable formation of pentosans in the generator. No appreciable loss in solids or nonsugars takes place, and the other constituents are practically unaffected. The amount of glycerol in the cider remains almost unchanged by its passage through the generator, and, as it is a product of the alcoholic fermentation, it is an important factor for the detection of adulteration in commercial vinegars. The percentage of ash in the nonsugar solids is remarkably constant, varying only within slight limits, and is of decided value as a standard for judging the purity of cider vinegars.

"The results indicate plainly that, given the composition of a hard cider to be used in this manufacture of vinegar by the generator process, it is possible to approximate very closely the composition of the vinegar which can be made from it."

The physiological significance of certain substances used in the preservation of food, J. H. LONG (*Trans. 15. Internat. Cong. Hyg. and Demogr. Washington, 2 (1912), Sect. 2, pp. 360-371*).—A résumé of work and discussion regarding the use and physiological effect on sodium benzoate, copper salts, and sulphurous acid in food materials.

The physiological significance of certain substances used for the preservation of foodstuffs, A. SCHATTENFROH (*Trans. 15. Internat. Cong. Hyg. and Demogr. Washington, 2 (1912), Sect. 2, pp. 371-380*).—A discussion of the effects of formic acid, boric acid, borax, sulphurous acid, salicylic acid, benzoic acid, hydrogen peroxid, formaldehyde, etc., on the physiological processes and their desirability as preservatives.

Cost and nutritive value of foods, C. F. LANGWORTHY (*Trans. 15. Internat. Cong. Hyg. and Demogr. Washington, 2 (1912), Sect. 2, pp. 550-573*).—A survey of the work done in the United States from 1907 to 1912 along the following lines: Studies of food and food products; special studies of ash, protein, and other food constituents; preparation, preservation, handling, and storage of food in relation to nutritive value; dietary studies and dietetics; digestion; metabolism experiments, including studies of income and outgo, made with respiration calorimeters; hygienic studies of foods in relation to their economic value; cost and economic value of food and other statistical data; and agencies for making information available.

A complete list of the publications referred to is appended.

Statistical data regarding the protection of food supplies in large cities in Germany, edited by H. SILBERGLEIT (*Statistische Beiträge zur Frage der Lebensmittelversorgung in deutschen Grossstädten. Berlin, 1912, p. 75*).—A summary of data, chiefly statistical, regarding slaughterhouse prices, sales, and other topics connected with the trade in meat, fish, and potatoes.

Retail prices, 1890 to August, 1913, F. C. CROXTON (*U. S. Dept. Labor, Bur. Labor Statis. Bul. 136, 1913, p. 146*).—In this publication, which is No. 11 of the Retail Prices and Cost of Living Series (E. S. R., 30, p. 259), statistical data are reported, chiefly in tabular form, regarding the prices of food, coal, and gas, and the scaling weight (i. e., weight of dough before baking) of the principal brands of wheat bread, the investigation covering a number of American cities.

The influence of preparation upon foodstuffs and their nutritive value, M. RUBNER (*Trans. 15. Internat. Cong. Hyg. and Demogr. Washington, 2 (1912)*).

Sect. 2, pp. 591-602).—A survey of the common ways of preparing different classes of food materials for use and of the effect which the changes thereby produced have upon their digestibility.

Around-the-world cook book, MARY L. BARROLL (*New York, 1913, pp. VII+360*).—A collection of recipes, which, the author states, have been gathered from many sources in the United States and elsewhere.

Influence of quality and quantity of the food upon the growing organism, H. ARON (*Trans. 15. Internat. Cong. Hyg. and Demogr. Washington, 2 (1912), Sect. 2, pp. 451-456*).—A discussion, illustrated in part by the author's experiments with dogs, of the rôle played by the different food constituents in growth and of the beneficial effects of a generous diet.

Influence of chronic undernutrition upon metabolism, N. ZUNTZ, S. MORGULIS, and M. DIAKOW (*Biochem. Ztschr., 55 (1913), No. 3-4, pp. 341-354; noted in Biochem. Bul., 3 (1913), No. 9, pp. 72, 73*).—Respiration experiments were made periodically with a dog which was fed on constantly decreasing diets for a little more than a year, the weight and body temperature of the animal being noted daily during the entire time.

It was found that the energy utilized per square meter of body surface sank from 931 calories with an original weight of 10 kg. to a minimum of 631 calories with a weight of 4.98 kg. in the eleventh month and rose again to 921 calories with a weight of 4.10 kg. just before death in the thirteenth month. No typical differences were noted between the metabolism in this long continued undernutrition and that observed with fasting subjects. The natural expectation that the energy utilization would gradually tend to adapt itself to the insufficient food provided was not fulfilled. In fact, the contrary appeared toward the close of life.

The specific dynamic effect of foodstuffs, M. RUBNER (*Trans. 15. Internat. Cong. Hyg. and Demogr. Washington, 2 (1912), Sect. 2, pp. 383-389*).—A discussion of the author's theory that each food ingredient entails a characteristic increase in the energy transformed in the body.

The increase ascribed for the different ingredients is given as follows: Cane sugar, 5.8 per cent; fat, 12.7 per cent; and protein, 30.9 per cent. These values are termed by the author specific dynamic effect.

The work of digestion and specific dynamic action of foodstuffs, N. ZUNTZ (*Trans. 15. Internat. Cong. Hyg. and Demogr. Washington, 2 (1912), Sect. 2, pp. 390-394*).—A discussion of the problem of the increased metabolism following the ingestion of food from which the conclusion is drawn that the increase is chiefly due to the increased mechanical work of the digestive tract.

The influence of the ingestion of food upon metabolism, F. G. BENEDICT (*Trans. 15. Internat. Cong. Hyg. and Demogr. Washington, 2 (1912), Sect. 2, pp. 394-400*).—Basing his arguments upon the work of Müller and on original experiments (E. S. R., 27, p. 666), in which metabolism was measured after the ingestion of purgatives of nonabsorbable agar-agar as well as carbohydrates, etc., the author concludes that the increased metabolism after the ingestion of food is not due to mechanical activity in the digestive tract, but rather to the stimulus exerted on the general metabolism by the cleavage products of the food constituents.

The influence of foodstuffs and their cleavage products upon heat production, G. LUSK (*Trans. 15. Internat. Cong. Hyg. and Demogr. Washington, 2 (1912), Sect. 2, pp. 400-409*).—Respiration calorimeter experiments with dogs appear to the author to demonstrate "(1) that the increase in metabolism after protein ingestion is due to the stimulus of certain amino acids acting on protoplasm and (2) that the increase in metabolism after giving sugar and fats is

due to the increase of these metabolites in the blood stream." "There are the following forms of metabolism in the quiet or sleeping dog excluded from thermal influences: (1) A basal metabolism, in which the cells are nourished by a blood stream which does not receive food from the intestinal tract, but the composition of which is regulated by the organs of the body; (2) a metabolism due to plethora, induced by an increased quantity in the blood of carbohydrates or fat metabolites which are being absorbed from the intestine; and (3) a metabolism due to the stimulus of certain incoming amino acids acting upon the cells. The metabolism of plethora and the metabolism of amino acid stimulation can not be added to each other; there is no summation of effect when both influences are brought into action together. In other words, the rhythm of cellular motion induced by the presence of carbohydrates is not further intensified by the stimulus of amino acids, unless the latter alone would accomplish the result."

The rôle of proteins in growth, L. B. MENDEL (*Trans. 15. Internat. Cong. Hyg. and Demogr. Washington, 2 (1912), Sect. 2, pp. 429-438*).—A summary and discussion of the work done by Osborne and the author in feeding rats with isolated protein substances (E. S. R., 24, p. 304; 25, p. 864; 28, pp. 863, 864).

Studies of protein minimum, M. HINDHEDE (*Skand. Arch. Physiol., 30 (1913), No. 1-3, pp. 97-182, 228, figs. 5*).—This work is based on experiments similar to those previously reported (E. S. R., 28, p. 564) with subjects living on diets consisting mainly of potatoes and fat. The nitrogen content of the diets was very low, varying approximately from 3 to 8 gm. per day.

The author interprets the results as indicating that the protein minimum varies with individuals as it does with the same individual under different conditions of muscular activity. In these experiments, all excess of protein in the diet [*Luxusverbrauch*] is believed to have been absent, and the nitrogen excreted, therefore, represented only the inevitable loss of body cells. The results indicate that the utilization of protein during muscular work increases in the same ratio as, or one slightly greater than, that of energy.

The nutrition and growth of bone, F. H. MCCRUDDEN (*Trans. 15. Internat. Cong. Hyg. and Demogr. Washington, 2 (1912), Sect. 2, pp. 424-429*).—According to the author, bone, like other tissues, undergoes metabolism throughout life. When the new bone, which is constantly being formed, is not of proper composition, various diseases (rickets, etc.) may result. Bones serve as a storehouse of lime salts, according to the author, just as the liver serves as a storehouse of glycogen.

The antagonistic action of salts, J. LOEB (*Trans. 15. Internat. Cong. Hyg. and Demogr. Washington, 2 (1912), Sect. 2, pp. 457-463*).—In answering the question as to what is the physiological function of salts in the organism, the author emphasizes that of safeguarding the specific permeability of cells, a function which finds its expression in the so-called antagonistic salt action.

He carried on experiments with muscular tissue and eggs of the marine fish *Fundulus*, the results of which he summarizes as follows: "The antagonistic action of salts is due, in all cases where an analysis of these phenomena is possible, to a prevention of the increase in permeability which a salt would have if it were alone in solution. The fact that these injurious effects are reversible indicates that the changes in permeability may play a great rôle in the physiology and pathology of cells, a fact to which Osterhout has also called attention. The experiments show that the salts are responsible for the reversibility of the increase in permeability. It is also of importance that these experiments seem to prove that the antagonistic action of acids and salts, and possibly of electrolytes in general, is due to an action upon proteins."

The rôle of surface tension in determining the distribution of salts in living matter, A. B. MACALLUM (*Trans. 15. Internat. Cong. Hyg. and Demogr. Washington, 2 (1912), Sect. 2, pp. 463-474*).—The author summarizes the points made in this address, much of which is based on original microchemical investigations, by emphasizing "how far surface tension is a factor in determining the distribution and localization of salts in the fluids and tissues of the body. The forces governing the distribution of salts in ordinary solutions are profoundly modified in tissues and organs by the action of surface tension, which . . . is a very important factor in the processes of secretion and excretion. The part this force plays in determining the inorganic composition of the tissues and in influencing the functions of the organs" seems to him to justify that emphasis.

Lime requirements of man, H. KRUSPE (*Tonindus. Ztg., 37 (1913), No. 78, pp. 1024, 1025*).—According to the author's estimate, the amount of calcium oxid required per day is 1 gm.

The calcium oxid content of several foods is quoted. The author is of the opinion that the amounts of these eaten per day do not supply the necessary calcium oxid, so advises that calcium chlorid solution be added when bread is made, the amount being equivalent to 2 gm. calcium oxid per kilogram of flour.

The importance of nutritive salts in health and disease, R. PETERS (*Trans. 15. Internat. Cong. Hyg. and Demogr. Washington, 2 (1912), Sect. 2, pp. 628-639*).—A general discussion of the functions of the salts in food material in the light of some of the recent European observations and investigations.

The choice of foodstuffs in relation to disease, C. VON NOORDEN (*Trans. 15. Internat. Cong. Hyg. and Demogr. Washington, 2 (1912), Sect. 2, pp. 574-583*).—A discussion of dietetics with special reference to such pathological conditions as obesity, undernutrition, gout and the uric acid diathesis, diabetes mellitus, fever and Graves's disease, diseases of the stomach and intestines, and diseases of the kidney.

Diet as a weighty factor of causal therapeutics in severe diseases of the stomach and intestines, in troubles of metabolism, kidney troubles, disorders of the circulation, in pulmonary diseases, and in nervous and mental diseases, W. PLÖNIES (*Trans. 15. Internat. Cong. Hyg. and Demogr. Washington, 2 (1912), Sect. 2, pp. 483-535*).—A diet of starch, white of egg, and lean meat combined with complete rest is indicated for all diseases which have their primary cause in gastro-intestinal disorders and the consequent production of toxins or the impairment of the bactericidal function of the small intestine.

Diet in relation to disease, A. HOLST (*Trans. 15. Internat. Cong. Hyg. and Demogr. Washington, 2 (1912), Sect. 2, pp. 583-590, 619*).—This paper, much of which is based on data gathered in the author's laboratory, discusses the curative or preventive effect of different food materials on human and experimental scurvy, beri-beri, and polyneuritis gallinarum. It emphasizes the apparently opposite action of certain apparently similar food materials, citing, for example, the fact that scurvy on board ships in which dried potatoes were included in the diet has been cured when a supply of fresh potatoes has been obtained. Another example is that, although wheat bread always produces polyneuritis in pigeons, it appears much later when yeast is used instead of baking powder. Attention is also called to the fact that, whereas chickens fed on meat boiled for an hour at 100° C. do not develop polyneuritis, when they are fed on meat boiled for an hour at 120° they die of the disease and that they contract it with meat boiled half an hour at 110°.

To quote from the author's summary: "On the whole, our present knowledge of the diet in relation to beri-beri and scurvy shows that, in our daily food,

and, above all, in the vegetable nutriments, there are mysterious forces at work, the outlines of which are only just beginning to appear. . . . When fed on oats or barley only, guinea pigs constantly die from scurvy; but if we moisten the grains and make them sprout—that is, when we convert them into fresh vegetables—they prevent the disease.”

Relation of oysters to the transmission of infectious diseases, H. D. PEASE (*Trans. 15. Internat. Cong. Hyg. and Demogr. Washington, 4 (1912), Sect. 5, pp. 203–213*).—In this paper, what the author believes to be the best informed opinion regarding infection by shell fish is summarized as follows:

“Outbreaks of acute gastro-intestinal disturbances and of typhoid fever have been shown to be due to the consumption of raw oysters and clams which have been floated in specifically polluted waters during a nonhibernating season of the year for these shellfish, but . . . no evidence exists that oysters taken from their natural or final maturing beds during any season of the year, nor that any oysters—floated or not—during their hibernating period, have ever caused outbreaks or endemic conditions of any infectious disease. . . .

“The burden of official supervision, therefore, is determined by the life cycle of the oysters and the practical requirements for the conduct of the business. The important point is to determine the sanitary conditions of the drinking places during the late summer and early fall months. When this has been accomplished, it will doubtless be found that oysters taken from waters in at least the more northern sections of the Atlantic coast have ceased to be a factor in the transmission of infectious diseases.”

[Shellfish and transmission of disease], G. A. SOPER (*Trans. 15. Internat. Cong. Hyg. and Demogr. Washington, 4 (1912), Sect. 5, pp. 211–213*).—In an informal discussion of the paper noted above, emphasis is laid on the importance of controlling the use of hard or little-neck clams and also of soft clams from polluted waters.

“Unlike the oyster, which requires a rather firm, clean bed, the hard clam grows well in a muddy bottom. Sewage sludge itself is not unfavorable to it. It is not unusual to see persons digging hard clams close to the mouths of sewers. After a very short period in market this form of shellfish is often eaten raw. Hard clams are particularly in favor during those warm months when oysters are out of season and diarrheal diseases are most common. It would not be at all surprising if many outbreaks of diarrheal disease at seaside summer resorts were traceable to hard clams taken from nearby polluted sources. . . .

“What are known as soft clams in New York, but are simply termed clams in New England, are more often found in sewage polluted localities than are oysters or hard clams. They grow deeply buried in sand or mud, and are dug out of their resting places when the tide recedes and leaves their beds bare. Heavily polluted shores are among the most prolific sources of soft clams, and large quantities are annually taken from situations of this kind. . . .

“Unlike oysters and hard clams, which are now extensively planted and grown for market, soft clams are taken only in the wild state. . . . The persons who gather them usually consume them in their own homes, or distribute them among friends. To control the purity of soft clams will be more difficult than to prevent the pollution of oysters, but the beneficial results to be obtained would seem to make the effort well worth while.”

Some calorimetrical investigations relating to the manifestation and amount of imbibition heat in tissues, V. E. NIERSTRASZ (*K. Akad. Wetensch. Amsterdam, Versl. Wis en Natuurk. Afdcel., 20 (1911–12), pt. 2, pp. 1013–1024, fig. 1; Proc. Roy. Acad. Sci. Amsterdam, Sect. Sci., 14 (1912), pt. 2, pp. 1130–1138, fig. 1*).—The apparatus used in these experiments, called a bolometer by

the author, was a specially constructed differential calorimeter provided with sensitive electrical resistance thermometers.

Dried and powdered preparations of muscles and other tissues from cold-blooded (fresh-water mussel) and warm-blooded (rabbits and pigeons) animals were brought into contact with water in the calorimeter and the heat given off during the process of imbibition (real molecular swelling) was measured. It was found that all the materials tested were liable to imbibition, the process being attended by a considerable development of heat. Generally speaking, muscle tissue developed greater heat than kidney and liver.

Differences between tissues from different types of animals were less marked, though noticeable. The sensibility of the method is said to be very great, one division mark on the measuring wire representing an average of 0.001 or 0.002 gm.-calorie.

The work is of technical interest as suggesting new methods of research into the nature of some of the more obscure changes occurring in body tissue, and possibly into the action of digestive juices, etc.

Direct calorimetry of infants, with a comparison of the results obtained by this and other methods, J. HOWLAND (*Trans. 15. Internat. Cong. Hyg. and Demogr. Washington, 2 (1912), Sect. 2, pp. 438-451, fig. 1*).—A description of the methods used and the results obtained in respiration calorimeter experiments with infants under various conditions of nutrition.

ANIMAL PRODUCTION.

The element of uncertainty in the interpretation of feeding experiments, H. H. MITCHELL and H. S. GRINDLEY (*Illinois Sta. Bul. 165, pp. 463-579, pl. 1*).—In this bulletin the authors point out that many simple feeding experiments are of more or less ambiguous significance because of the dissimilarity which exists among the gains of individual animals, due to variable, uncontrolled, and largely unknown experimental conditions. Methods are proposed for "dealing with the question in a systematic and rational manner, so that the sphere of uncertainty surrounding the conclusions based on experimental results will be reduced to a minimum and be defined as clearly as possible."

It is first shown that all attempts to predict the result of repeating an experiment must be based on the "tendency of comparable experimental data to assume a definite frequency distribution, expressible by a frequency curve capable of mathematical definition." It is further explained that "an average is at best only an imperfect description of a series of experimental data, and when used for comparative purposes is often extremely misleading." The use of a factor, known as the standard deviation, is advised in comparing the gains exhibited by 2 different lots of animals and may be defined as "the square root of the average squared deviation of all individual gains from the average gain for the lot." On the basis of this standard deviation, the probable error to be encountered in predicting the result of repeating a feeding experiment may be determined. By the use of such a probability method it is possible to interpret the results of feeding experiments in a fairly satisfactory manner.

For extensive comparisons of variation "the coefficient of variation is used, this coefficient being simply the standard deviation calculated at a percentage of the average. The coefficient of variation of gains within lots is a good measure of the experimental error." From an extensive review of experiment station literature in this country it is found that the average coefficient of variation gains for similarly treated lots of sheep is about 21, for steers and swine about 17, and for poultry about 16 per cent.

Calculations indicate that experimental lots should contain at least 10 to 14 animals, or even 25 to 30 animals, when the rations or other conditions under

investigation are very similar. However, increasing the size of the lots is no remedy for a poor selection of experimental animals, nor can increased size of lots eliminate the element of individuality. The beneficial effect of increasing the size of lots varies not with the number in the lot, but with the square root of this number. Uniformity of gains within the lot is desirable and can be obtained by a reduction in the coefficient of variation of gains. The experimental error may be reduced by the selection of experimental animals homogeneous as regards age, breed, type, sex, and previous treatment. In this connection it has been found that as a rule lots exhibiting the best average gains also exhibit the more uniform gains, and vice versa; also that the changes in the variability of gains during an experiment may be materially reduced when conditions are constantly or increasingly favorable to growth and fattening.

Experimental evidence indicates that physiological selection of experimental animals does not eliminate the poor gainers, and that such selection is very inefficient in reducing experimental error, even when conducted along the most rigorous lines.

The difficulty which some stations have had in duplicating experiments and results leads to the conclusion that the frequent tendency to generalize from data of a very specific description should be carefully guarded against. It is further recommended that experimental rations be submitted to a chemical analysis, for "the practical utility of average analyses is limited, and in the case of many of the grains and roughages is small, indeed." On the other hand, the individual feeding of animals in ordinary feeding trials is deemed unnecessary and entirely out of harmony with ordinary practice.

In concluding this bulletin the authors present their views relative to the publication of results and the formulating of results, showing wherein caution and precision must be used when asserting that a given experiment indicates a superiority of one ration over another.

There are appended statistical data concerning the rate of growth of sheep, swine, steers, and poultry; formulas for determining the number of animals to include in an experimental lot; additional data on the change in variability of gains in weight as related to feed consumption; and a bibliography of 84 references.

The element of uncertainty in the interpretation of feeding experiments, H. H. MITCHELL and H. S. GRINDLEY (*Illinois Sta. Bul.* 165, *abs.*, pp. 2-8).—This is a popular edition of the above bulletin.

An investigation of the feeding value of flax material as determined by chemical analysis, J. W. INCE (*North Dakota Sta. Bul.* 106, pp. 10-29).—This article includes a summary of data as to the feeding value of flax straw and flax plant by-products, with comments on the extensive use of these materials in commercial stock feeds. The average composition of flax materials, as shown by analyses of materials collected in North Dakota in 1912, is given in the following table:

Analyses of flax materials.

Kind of material.	Moisture.	Protein.	Ether extract	Nitrogen-free extract	Crude fiber.	Ash.
	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>	<i>Per ct.</i>
Flax straw, brown.....	4.47	9.22	4.03	4.06
Flax straw, green.....	4.96	7.87	4.17	5.34
Flax screenings.....	5.29	18.10	8.97	7.18
Flax chaff.....	4.86	9.06	3.42	7.20
Flax bran.....	5.96	9.08	3.57	34.51	39.78	6.01
Green flax straw shives.....	4.69	8.00	1.93	29.36	51.85	4.17
Dew-rotted flax straw shives.....	4.30	3.44	1.29	29.08	59.30	2.59

From the results of a feeding experiment, previously noted (E. S. R., 29, p. 366), the opinions and experiences of several farmers as to the feeding value of flax products, and other data, it is concluded that the farmer is justified in feeding these products in moderation, with due precautions against poisoning. Additional feeding experiments, however, are regarded as desirable.

Grape foliage in animal feeding, J. GIRARD (*Jour. Soc. Cent. Agr. Haute-Garonne*, 23 (1913), No. 245, pp. 171-176).—Grape foliage is fed to cattle either dried or ensiled, and is found to be both palatable and nutritious. The silage is preferred. As a forage, the leaves retain their green color and possess a pleasant odor. The usual daily allowance is from 10 to 15 kg. (22 to 33 lbs.) per head together with a grain ration.

Investigations on the change in the nutritive value of feeds from ensiling and on the consequent loss of nutritive value, IV, A. ZAITSCHEK (*Landw. Vers. Stat.*, 78 (1912), No. 5-6, pp. 401-408).—This is a continuation of work previously noted (E. S. R., 25, p. 479; 26, p. 360), experiments in feeding swine being conducted to determine the comparative feeding value of fresh and ensiled beets.

It is noted that the nutritive value and digestibility are lowered as the result of ensiling. This loss was especially noticed with beets stored for the entire winter and removed in the spring. Beets removed from storage in February suffered less loss of sugar and other nutrients. The net available energy value of fresh beets is reported as 38.04 calories per kilogram, and for ensiled beets 33.73 calories.

Silo and silage catechism, R. H. MASON (*South Carolina Sta. Circ.* 12, pp. 3-16, figs. 6).—A general circular treating of the different types of silos, silo construction, silage crops, filling the silo, and feeding silage.

Fodder and method of making same, V. CHRISTENSEN (*U. S. Patent* 1,073,591, Sept. 23, 1913; *abs. in Jour. Soc. Chem. Indus.*, 32 (1913), No. 20, p. 987).—"The concentrated saccharin juice of the agave is mixed with nitrogenous and cellulose substances, and the mixture dried and ground to form a 'conservable complete fodder.'"

Comparative value of brewery residue mixed feeds for ruminants, W. VÖLTZ, W. DIETRICH, and A. DEUTSCHLAND (*Wchnschr. Brau.*, 30 (1913), No. 45, pp. 575-578).—In sheep-feeding trials mixed feeds of chopped straw and brewery residue, and turf meal, charcoal, and brewery residue were fed. The relative digestibility, starch value, and feeding value of these feeds were determined and their economy demonstrated. The starch value for the chopped straw mixture was estimated at 55.65 kg. per 100 kg. of dry matter and that of the turf meal mixture at 23.85 kg.

Peanut bran in Germany, R. P. SKINNER (*Daily Cons. and Trade Rpts.* [U. S.], 16 (1913), No. 270, pp. 890, 891).—An account is given of the use of peanut shells and the red hulls which envelop peanut kernels for stock feeding. The shells are high in cellulose content and low in nutritive value, but the material is mixed with other feeds of higher value and is frequently used in the composition of molasses feeds to give them body. Peanut bran made from the hulls is said to contain varying amounts of fat and is considered a serviceable secondary stock feed.

Commercial feeding stuffs, R. F. KOLB and B. B. ROSS (*Feed Stuff Bul. Ala. Dept. Agr.*, 1911-12, No. 54, pp. 64).—This bulletin includes a discussion of the nutritive value of feeding stuffs, the calculation of rations, and the dangers resulting from the feeding of spoiled feeds. Analyses are reported of middlings, shorts, bran, screenings, molasses feed, dried beet pulp, mixed feeds, and pro-

prietary stock feeds. The text of the Alabama commercial feeding stuffs law, together with the feed definitions as adopted in 1911 and 1912, is included.

Steer-feeding experiments, W. H. TOMHAVE and B. O. SEVERSON (*Pennsylvania Sta. Bul. 124, pp. 23-39, figs. 4*).—In these experiments 2 lots of 12 steers each, weighing approximately 900 lbs., were fed during 140 days as follows: The steers in lot 1 received all the corn silage they would consume during the first 2 months of the feeding period, together with 3 lbs. cotton-seed meal per 1,000 lbs. live weight daily. At the end of 56 days they were fed in addition to this combination all the ear corn they would consume, this being replaced by shelled corn the last 2 months of feeding. Lot 2 received as roughage 20 lbs. corn silage per day per head and all the mixed hay they would consume during the first 56 days, together with 3 lbs. cotton-seed meal per 1,000 lbs. live weight daily. During the remainder of the period they were fed shelled corn as in lot 1.

The average daily gain per head for lot 1 was 1.944 lbs., for lot 2, 1.803 lbs.; the respective costs per pound of gain were 8.31 and 9.46 cts.; the profit per steer, not including pork, \$14.10 and \$11.22; the price received from a bushel of corn after paying for other feeds \$1.47 and \$1.31. Hogs following lot 1 gained 611 lbs., in lot 2, 575 lbs., increasing the total returns per steer \$2.23.

It is concluded that the feeding of corn silage alone as a roughage is the more satisfactory of the 2 methods of feeding, this experiment bearing out results of previous tests. Because of the palatability of corn silage the advisability of limiting the amount of silage in the ration in order to insure the greatest gain in flesh during the finishing period was demonstrated.

Comparative experiments in fattening sheep of the middle valley of the Tiber and the cross-bred Merino-Rambouillet; with some observations on the organic changes, G. TASSINARI (*Staz. Sper. Agr. Ital., 46 (1913), No. 1, pp. 57-78*).—In these digestion experiments the cross-bred sheep gave somewhat better results, taking on more fat and assimilating a greater portion of the feed allowance.

The management of sheep on the farm, E. L. SHAW and L. L. HELLER (*U. S. Dept. Agr. Bul. 20, pp. 52, pls. 4, figs. 15*).—This is a popular treatise on the value of sheep on the farm; the selection of stock; the feed, care, and management of sheep; caring for lambs; tagging, dipping, castrating, and docking. Plans for construction of feed racks are given. Shearing and care of wool, slaughtering, and the care of meat are discussed.

[Report of] sheep and wool expert, J. W. MATHEWS (*Rpt. Dept. Agr. N. S. Wales, 1912, pp. 55-59*).—This report first emphasizes the importance of the future development of the Merino to New South Wales. It is shown that many of the flocks have attained their present standard of perfection only after life-long work on the part of the breeders, and that closer settlement must necessarily result in the breaking up of many of these old established flocks. In view of this fact it is urged that the government take measures for the preservation of the Merino, and that a great state station be established which will supply New South Wales, Australia, and ultimately the world, with the purest and finest types of Merino that the country can produce.

In cross-breeding experiments the heaviest body weights were obtained from the Dorset Horn-Merino, Lincoln-Merino, and Border Leicester-Merino crosses in the order named, the Down breeds proving unsatisfactory. The heaviest fleeces were obtained from the Lincoln-Merino, Border Leicester-Merino, and Leicester-Merino crosses. Data are given showing the aggregate value of each type of cross-bred sheep, live and dressed weights, and weights of fleece for both local and foreign trade.

Australasian wool clip (*Daily Cons. and Trade Rpts. [U. S.], 16 (1913), No. 264, p. 759*).—The Australasian wool clip production for the current 12 months

is estimated at 2,407,000 bales, an increase of 160,000 bales on the output in the 1912-13 season.

An experiment in pig feeding and fattening on sugar cake, C. MANICARDI (*Indus. Latt. e Zootec.*, 11 (1913), No. 6, pp. 86, 87; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 6, p. 933).—In experiments with 40 pigs it was found that those fed a special brand of sugar cake, described by Cugnini on page 375, presented superior fattening results and more economical returns than those fed farinaceous feeds.

Country hams and bacon, and market classifications of pork products, W. L. NELSON and L. D. HALL (*Missouri Bd. Agr. Mo. Bul.*, 11 (1913), No. 6, pp. 53, figs. 32).—This deals with the preparation of country hams and bacon, but more especially with the market classification of these products. Some of the material has been taken from Bulletin 147 of the Illinois Station, previously noted (*E. S. R.*, 24, p. 69).

The inheritance of coat color in the horse, A. R. WALTHER (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps.*, 1911, pp. 491-502, figs. 6).—The author's observations and investigations are summarized as follows:

"There are 2 principal colors found in horses' coats, viz, yellow and red. These 2 colors, generally combined with black points, are the components of the coat colors of the wild horse (*Equus przewalski sp. equiferus*). . . . Yellow and red are allelomorphic to each other. Two yellow horses give rise to yellow horses and, in lesser numbers, to red horses. . . . Yellow is therefore dominant to red. These principal colors may be modified by 4 kinds of supplementary markings: Black marks (melanism), white hairs (leucotrichia), marks of the piebald horses (tacheture, leucodermia), white stockings (balzanes). The 3 first are always epistatic on the principal color, and on each other, in the order named. . . .

"Albinism is very rare. It is probably a recessive. There is no direct connection between albinism, leucodermia, and leucotrichia."

[German horse control brands], KLUTE (*Deut. Landw. Tierzucht*, 17 (1913), No. 43, pp. 512-516, figs. 31).—A description of the various control brands in use in the studbooks of the several Provinces of the German Empire.

Report of the poultry husbandman, H. R. LEWIS and A. L. CLARK (*New Jersey Stas. Rpt.* 1912, pp. 99-103, 124-156, pls. 19).—In a study of the 3 different types of brooders, outdoor individual, kerosene indoor, and gasoline, it is concluded that the latter is the more efficient for the average farm poultryman.

It is stated that sprouted oats is one of the cheapest and best sources of winter succulence for fowls. The best results were obtained in sprouting oats, when they were sprouted in a warm place (60 to 80° F.), light or darkness being immaterial; previously soaked for one day; placed in trays to a depth of not more than one inch; and water applied once a day, very little the first 2 days and more as the growth advances. The use of nitrogen showed no benefits. Oats proved more suitable than barley, wheat, or rye.

Rations are suggested for a dry mash, summer dry mash, scratching ration, and night ration. In a 9 months' test of the laying capacity of 328 hens of different breeds the following percentage egg yield was obtained: White Leghorns and Rhode Island Reds 40, White Plymouth Rocks 37, White Orpingtons 32, Buff Orpingtons 31, Black Langshans 27, Barred Plymouth Rocks and White Wyandottes 26, and Light Brahmas 17. In general, there was noted among all the heavy layers a long body in proportion to its depth, with the heavy development behind forming a wedge shape when viewed from the side, late molting, a faded shank, bright full eye, often faded in color and free from surplus face wrinkles. The poorer producers were noted for an early molt and general sleek appearance.

An account is given of the reading courses and educational work being conducted, together with a statistical review of the poultry industry in New Jersey.

The Philippine chicken, V. F. ALLABEY (*Philippine Agr. and Forester*, 2 (1912), No. 4-6, pp. 49-55).—A study was made of the physical characteristics and utility value of the native Philippine chickens. They were found to have no established and well-defined type, and no fixed color. Their shanks are not feathered. The skin is usually white, but sometimes yellow or black. The hens are fairly good sitters and mothers. Practically no attention has been given to breeding, except for the production of game cocks. The eggs are small, and the hens seldom lay more than 8 eggs in one laying period and often become broody after laying 5 or 6. It has been demonstrated that native hens will not produce profitably if confined to the yard. The weight of the native chicken is surprisingly small, and it is thought that because of this there is little chance of developing a meat breed by crossing the native chicken with the meat breeds of other lands.

Experiments performed in order to obtain fixed and lasting varieties of poultry, R. HOUWINK (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps.*, 1911, pp. 524-533, figs. 40).—As the result of observations made of the variations in the native breeds of Drent, Holland, especially as regards the form of comb, wattles, and toes, presumably due to the rigors of climate, experiments were made to determine the relative influence of these environmental agencies in establishing fixed and lasting variations. The conclusion reached by the author is as follows: "Natural selection produces fluctuating variations in races of hardy fowls. By continued breeding of these fluctuating varieties, produced by natural selection, new fixed races may be formed. In agreement with Darwin's theory, the formation of races may be explained not only by mutations but also by fluctuating variations produced by natural selection."

Hybrids of the Barbary duck with the farmyard duck: Their egg laying capacity and their eggs, A. CHAPPELLIER (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps.*, 1911, pp. 503-506).—The author's observations confirmed the work of Poll in 1906 to the effect that the hybrids between the Barbary duck and the farmyard duck differ considerably in the development of the ovary according to which species is used as the male parent. The use of a male Barbary duck resulted in nonlaying female hybrids which possess a rudimentary Fallopian tube and ovaries bearing no trace of ovules. The females of a reciprocal cross produce a large number of eggs, but the eggs are always sterile. The average weight of the eggs from the hybrid is about two-thirds that of the eggs of either of the parents.

The duck and egg business of Pateros, M. B. RAYMUNDO (*Philippine Agr. and Forester*, 2 (1912), No. 4-6, pp. 56-59).—An account of the duck industry of Pateros, a town situated 10 miles from Manila, and for generations known because of its proficiency in this industry. Interesting methods of incubation, care, and management are described.

Report of the biologist, J. NELSON (*New Jersey Stat. Rpt.* 1912, pp. 281-345, pls. 8).—In securing data on oyster propagation for 1912 (*E. S. R.*, 28, p. 774), observations were made on the climatic, tidal, water, and filtration conditions at the Barnegat, Mullica, and Scullville stations.

Relative to spawning observations it is stated that the best oyster fry came from those individual oysters that spawn as near as possible to the date of the spawning climax, and, that as a general thing, "in our northern waters oysters spawn at a definite date, which can be foretold sufficiently early to allow of planting suitable cultch to catch the spat under the best conditions."

A couple of weeks generally intervene between the act of spawning and the act of "setting" of the spat, and spatting occupies but a few hours.

In experiments in coating tiles with various preparations to determine the effect of spatting it was found that copper paint and glaze were the poorest surfaces, while ordinary paint, gelatin, and linseed oil made a good showing. The best surface was the unglazed natural surface of the tile. In oyster shells coated with plaster no advantage was evident over those uncoated, while in clam shells the spat preferred the plaster coated.

A brief discussion is included on the floating of oysters (E. S. R., 27, p. 762).

DAIRY FARMING—DAIRYING.

Report of the dairy husbandman, A. S. Cook (*New Jersey Stat. Rpt. 1912, pp. 159-172, 193-202, pls. 4*).—Two lots of 2 cows each were fed for 30-day periods by the reversal system (15 days intervening between periods) on the following rations: Lot 1, corn and cob meal, and lot 2, corn meal, in addition to the regular basal ration composed of alfalfa hay, silage, corn stover, and cotton-seed meal. It is estimated that lot 1 received a daily ration of 22.45 lbs. dry matter, 1.596 lbs. protein, and 13.216 energy therms; lot 2, 22.67 lbs. dry matter, 1.666 lbs. protein, and 13.734 energy therms. For the entire period there was an increase of 90.2 lbs. of milk and 2.76 lbs. of milk fat in the corn meal ration. The cost of feed was 16.7 per cent greater in the case of the corn meal ration, and the corn and cob meal ration gave \$2.62 more profit than the corn meal ration or an increase of 17.5 per cent.

In comparing the efficiency of the different types of milk pails in the production of milk with a low bacteria count, the results with the Sterilac type showed 4,210 bacteria per cubic centimeter, the covered pail 5,375, the Gurler pail 7,240, the Sanitary pail 14,431, and the open pail 54,630.

Records are given of the station dairy herd in which it was found that the average milk production was 7,308.5 lbs., containing 278 lbs. of fat. The average net returns per dollar expended for feed, when roughage was figured at the cost of production, and milk at 5 cts. per quart was \$2.83, and when figured at the market price \$1.98. The total cost per quart of milk in the former case was 3.1 cts., and in the latter, 3.89 cts. The value of home-grown feed upon economical production is emphasized.

The "Pannello Zuccherino" (sugar cake) in the feeding of dairy cows, A. CUGNINI (*Ann. Ist. Agr. [Milan], 10 (1910-11), pp. 25-40, pls. 2; abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases, 3 (1912), No. 11, pp. 2482-2486*).—A report of feeding trials with a sugar cake made up of grape pomace meal, mixed with dry residues from the distillation of cereals and molasses, and containing approximately 14.34 per cent protein, 4.10 per cent fat, and 35 per cent nitrogen-free extract. Dairy cattle relished the feed and did well upon it.

Influence of the extracts of organs on milk secretion, L. GIUSTI (*Rev. Zootéc., 5 (1913), No. 49, pp. 6-11*).—The conclusions of the author are (1) that the extracts of organs which when injected into the body stimulate milk secretion are those of the hypophysis, corpus luteum, parotid, mammary glands, spleen, lymphatic glands, thyroids, thymus, fetus, and uterus; (2) that those which have no apparent effect are from the stomach, intestines, lungs, placenta, vagina, brain, heart, liver, kidneys, pancreas, suprarenal bodies, and testicles; (3) that the action is temporary and diminishes on reinjection; (4) that the results are noted when the organs are macerated or a decoction made from them; (5) that the extract of the organ possessing the greatest and most manifest action is that of the hypophysis; and (6) that the influence of the extract

of the hypophysis on lactic secretion is not alone on the quantity but also on the quality of milk, as denoted by an increased amount of fat.

[Relation between an increase of the average fat content of milk and the economy of production], N. HANSSON (*K. Landtbr. Akad. Handl. och Tidskr.*, 52 (1913), No. 5, pp. 289-369, figs. 12; *Meddel. Centralanst. Försöksv. Jordbruk-sområdet*, 1913, No. 78, pp. 85, figs. 12).—The author studied the possibilities of increasing the value of milk production by improving the fat content of the milk, and on the basis of results obtained in Swedish cow-testing associations ascertained the variations in the feed consumption per kilogram of milk fat in the case of milks of high and low fat contents and per kilogram of milk of different fat contents. The results thus reached are held to furnish an answer to the question as to whether it is economically advantageous to increase the average fat content of the milk by systematic breeding operations.

It is shown that the percentage of milk sugar and ash are practically constant in relation to the milk yield, while the albuminoids stand in a definite relation to the total solids, making up about 25 per cent of these. The milk fat of milk of low fat content is, therefore, accompanied by considerably more non-fatty solids than that of milk of high fat content; hence where the milk is used for butter production, or where it is paid for by the test, it is advantageous to increase the fat content of the milk so far as possible.

The amount of fat eaten per kilogram of milk fat (as measured by the "feed unit system") is decreased with an increasing fat content of the milk. An increase in the fat of the milk from 3 to 4 per cent, under otherwise similar conditions, means a saving of from 4 to $4\frac{1}{2}$ feed units in the amount of feed required per kilogram of milk fat. This saving is more marked in the case of milk low in fat than with rich milk, and is greatly reduced when the fat content reaches $4\frac{1}{2}$ to 5 per cent or more. The amount of feed eaten per kilogram of milk fat also depends on the milk yield obtained, since the returns for the feed eaten are lowest in case of poor yields. Rich milk requires a greater feed consumption than milk low in fat, and this greater consumption nearly corresponds to the increased solids content of the richer milk. Where all milk represents the same price, it pays best, therefore, to produce milk low in fat, while when payment is made according to fat content or nutritive value it is of advantage to produce milk high in fat or to increase the fat content of the milk so far as possible, since only about 30 per cent of the value of the fat secured by the increased fat content is required to pay for the resulting increase in the feed consumption.

The studies of the quality of the milk transmitted by breeding animals to their progeny show that it is possible to increase gradually the fat content of the milk by careful selection of individuals with an inbred faculty for producing milk of a fat content above that of the average for the family. The influence of male and female animals appears to be equal with regard to the fat content of the milk of the offspring, provided both represent a similar degree of constancy in their fat contents. Within the herd, however, the bull exercises the greatest influence through the larger number of his descendants. Variations always appear in the transmission of the fat content, for the reason that not only the special fat content of the sire and the dam and the faculty to transmit this fat content varies but there are also various plus and minus variants. The individual can thus have a fat content appreciably different from that of either parent, while the average for all progeny lies quite near to the average figure for the genotypic fat content of either parent. The aim of the herd improvement, when payment according to quality is decided upon, should be to reach not the highest possible percentage of fat in the milk, but the highest possible production of fat. The direct method of improvement in the average fat con-

tent of the milk consists in a rigorous selection of breeding animals, especially bulls, by which the ability of the bull to transmit a certain fat content is judged by the average fat content of his dam, granddams, and full sisters, by his sire's and grandsire's influence on their daughters, and when the bull is old, by his own influence on the average fat content of his progeny.

Many instances are given in the report of the beneficial hereditary influence of bulls and cows in Swedish dairy herds on the average fat content of the offspring.

Cost of milk production, F. RASMUSSEN (*New Hampshire Col. and Sta. Ext. Bul.* 2, 1913, pp. 20).—In reporting the results obtained in a year's work with one New Hampshire cow-testing association comprising 26 herds and 326 cows, the following facts are noted: The average yield was 6,463.6 lbs. of milk and 243.6 lbs. of milk fat; the average percentage of fat was 3.76; the average cost of feed was 2.4 cts. per quart; the returns per cow per year above feed cost were \$43.77; and the returns for each dollar's worth of feed consumed was \$1.59.

A classification of the cows in the order of amount of milk produced shows a decrease in profit with a decrease in production. The largest producers were on the average the most profitable. The estimated cost of keeping a cow per year is \$147.73, for which itemized statements are included. The production necessary for profit ranges from 6,000 to 8,000 lbs. of milk per cow.

Prices farmers received for market milk during 1912 (*Cream. and Milk Plant Mo.*, 2 (1913), No. 2, pp. 2, 3).—Inquiries conducted by the Dairy Division of this Department show that the average price paid for milk to farmers supplying 26 of the leading cities in the United States during the year 1912 was 3.565 cts. per quart, the lowest price paid being 2.904 cts. and the highest 4.437 cts. per quart. The highest average prices were paid during the months of October, November, December, January, and February, the lowest during May, June, July, and August. There is a large variation noted in the prices paid in the different cities.

The public value of different milks, C. E. NORTH (*Med. Rec.* [N. Y.], 84 (1913), No. 21, pp. 924-927).—This article discusses the relative value to the public of different grades of milk as determined by their cleanliness, safety, and price. Assuming that the maximum values of these 3 items are 25, 50, and 25, respectively, the several grades of pasteurized, certified, and raw milk are rated.

The milk supply of Karlsruhe, G. BERG (*Schr. Ver. Sozialpolit.*, 140 (1912), pt. 1, pp. VIII+168, pl. 1).—A complete description of the methods of feeding and management of dairy stock in vogue in Karlsruhe, with a statistical review of the milk production and consumption, market prices of milk, and sanitation regulations in operation in that city.

Dairying in western Norway, B. M. RASMUSEN (*Daily Cons. and Trade Rpts.* [U. S.], 16 (1913), No. 261, p. 697).—It is reported that though dairying is a leading industry in this district, it is backward as to scientific methods and machinery. There is a movement to reorganize the dairy industry along modern lines especially in the establishment of cooperative plants. However, poor transportation facilities and other factors render this plan difficult.

[Dairy inspection], W. D. SAUNDERS (*Quart. Rpt. Dairy and Food Comr. Va.*, 1913, June-Aug., pp. 36, 37, 56-60).—A brief report of dairy farm and creamery inspection in Virginia, and of examinations of proprietary stock and poultry feeds.

Proceedings of the Iowa State Dairy Association held at Waterloo, Iowa, October 10 to 14, inclusive, 1911 (*Iowa Yearbook Agr.*, 1911, pp. 347-388).—The addresses given before this association dealt with the power problem in the

creamery; the moisture content and the butter-fat standard; the good and bad points of the convention butter; improvements in butter manufacturing; ice-cream making and its relation to the creamery; daily testing of cream; and the North Iowa Dairy Improvement Association.

Dairy bacteriological practicum, J. F. HUSSMANN (*Molkereibakteriologisches Praktikum. Hanover, 1913, pp. XI+144, pls. 19*).—The contents of this book on milk bacteriology are as follows: Morphology and physiology of bacteria, technique of dairy bacteriology, a short description of the fission fungi of importance to the dairy industry, bacteriological control of the milk industry, methods of taking photomicrographs, etc. The book is illustrated with plates of the apparatus required for the different operations.

Review of agricultural microbiology, M. E. KAYSER (*Indus. Lait. [Paris], 38 (1913), Nos. 36, pp. 581-584; 37, pp. 596-598*).—In this article the author outlines the recent work in agricultural microbiology as applied to dairying. Studies on the bacteria of soured milk, cheese ripening, and milk cultures of various kinds are reviewed.

Annual report of the dairy instructor, A. CONLON (*Tasmania Agr. and Stock Dept. Rpt. 1912-13, pp. 20, 21*).—Reporting on the quality of Tasmanian export butter, the author states that Australian butter as a whole is deteriorating, and that energetic measures will be required to successfully compete with the high-grade margarin products that are being put on the British market.

Margarin v. butter (*Pastoral Rev., 23 (1913), No. 9, p. 921*).—In this article it is claimed that the neutral animal and vegetable fats used in margarin manufacture can be given a lactic acid flavor almost identical with that produced in butter. The margarin is produced in a room containing a number of vats filled with new milk, all of which are fermented by lactic acid bacteria. Further to improve the quality of this product, "a process of hardening liquid oils, such as cottonseed, soy beans, sunflower, etc., by means of hydrogen has been adopted, which completely removes all flavor and color, and at the same time solidifies the oil."

[Camembert cheese], C. GROUND (*Indus. Lait. [Paris], 38 (1913), Nos. 32, pp. 509, 510; 34, pp. 551-552*).—These are short articles treating on the manufacture and market value of Camembert cheese.

A practical method of preventing the unnecessary waste of condemned milk (*U. S. Dept. Agr. Press Notice, 1913, May 17, p. 1*).—With a view to denaturing condemned milk, thus rendering it unfit for human use but without destroying its value as a feed for stock, tests were made with a rennet solution. A 3 per cent water solution made from powdered rennet (strength 1:30,000) was used, and 40 cc. of this solution was added to 5-gal. cans of milk at temperatures of 50 and 65° F., with a resulting coagulation in approximately 1 hour.

The cost of material for this method of denaturing is estimated at 8½ cts. per 10 gal. of milk, when powdered rennet costs \$7 per pound.

Utilization of all of the constituents of milk, C. GROUND (*Rev. Gén. Chim., 16 (1913), No. 15, pp. 261-268*).—This discusses the probabilities of utilizing for various purposes the casein, lactose, and salts contained in milk. The methods for preparing casein from skim milk and sugar from milk serum are discussed in detail. From 1,000 kg. of milk about 30 kg. of casein containing 10 per cent of water can be obtained, and about 32 kg. of lactose and 8 kg. of molasses can be prepared from 1,000 kg. of milk serum. Other products considered are vinegar, milk beverages, and phosphates, especially calcium phosphate.

Industrial uses of casein, W. H. HUNT (*Daily Cons. and Trade Rpts. [U. S.], 16 (1913), No. 255, pp. 561-564*).—For industrial purposes casein is commonly extracted from skim milk by the use of a solution of concentrated sulphate of

magnesium. Recently it has been obtained by a process of electrolysis, which has the advantage of cheapness of production, increased yield, and greater purity.

The most important use of casein is in the manufacture of galalith (milk stone), which is used in imitation of ivory, tortoise shell, and celluloid. This product is prepared by molding and compressing the casein in the presence of formaldehyde. Numerous factories are found throughout France and Austria. In 1910 about 440,000 lbs. of casein were transformed into galatin at Surgère, Charente-Inférieure, where 35 dairies bring their milk to the casein factory. The residue, containing a large proportion of lactose, is returned to the dairies where it is used as a feed for pigs.

Casein is also put out in the form of vulcanized products, and is used in the clarification of wines.

VETERINARY MEDICINE.

Veterinary materia medica and therapeutics, K. WINSLOW (*New York, 1913, 7. ed., pp. 779*).—In this edition (E. S. R., 20, p. 1183), which has been revised and enlarged, the chapters on the physiological actions of ergot and digitalis have been entirely rewritten, and those on adrenalin and quinin have been changed in order to bring them up to date. Large additions have been made to the sections on the therapeutic actions of iodine, bismuth, magnesium sulphate, lysol, phenol, cocaine, sodium chlorid, arsenic, camphor, antiseptics, vaccines, and practical disinfection. Among the medicinal agents included for the first time in this book are glycerophosphates, picric acid, sodium cacodylate, chlore-tone, cresol, aspirin, novocain, thiosinamin, fibrolysin, yohimbin, and phenolphthalein. A complete section on poisons and antidotes has been added.

Handbook of pathogenic micro-organisms, edited by W. KOLLE and A. von WASSERMANN (*Handbuch der pathogenen Mikroorganismen. Jena, 1912, vol. 1, 2. enl. ed., pp. X+1057, pls. 3, figs. 154*).—The contents of this volume are as follows: Review of the Historical Evolution of the Study of Infection, Immunity, and Prophylaxis, by R. Abel (pp. 1-29); General Morphology and Biology of Pathogenic Micro-organisms, by E. Gotschlich (pp. 30-292); General Methods of Bacteriology, by E. Friedberger and H. Reiter (pp. 293-554); Nature of Infection, Mixed and Secondary Infection and Transference of Infectious Diseases by Inheritance, by A. von Wassermann and F. Keysser (pp. 555-631, 632-658, 659-684); Biochemistry of Antigens with Particular Reference to the Chemical Principles of the Specificity of Antigens, by E. P. Pick (pp. 685-863); Specificity of the Organisms causing Infection, and The Principles of Acquired Immunity (Active, General, Local, and Passive), by W. Kolle (pp. 869-904, 905-942); and Natural Immunity, by M. Hahn (pp. 943-1020). The first edition of this volume has been previously noted (E. S. R., 16, p. 601).

Protein split products in relation to immunity and disease, V. C., V. C., JR., and J. W. VAUGHAN (*Philadelphia and New York, 1913, pp. XII+17-476, figs. 34*).—This represents a detailed account of the investigations of the authors and their coworkers which began nearly 15 years ago.

In the introduction the theories relating to the physiological and pathological action of the protein split products are discussed under the following headings: (1) Bacteria are essentially particulate, specific proteins; (2) all true proteins contain a poisonous group; (3) the chemical nucleus does not become a poison until stripped in part at least of its secondary groups, and the intensity of its poisonous action is determined by the thoroughness with which the secondary groups have been removed; (4) when proteins are submitted to the action of disrupting agents there is the possibility of the chemical nucleus being

set free more or less completely, and to the extent that if it is detached it becomes a poison; (5) the pathogenicity of a bacterium is not determined by its capability of forming a poison, but (6) is dependent upon its ability to grow and multiply in the animal body; (7) any foreign protein which can grow and multiply in the body of a given animal may prove pathogenic to that animal; (8) the infectious diseases result from parenteral protein digestion; (9) natural immunity to any infection is due to inability of the infecting agent to grow in the animal body; (10) the immunity which is due to recovery from an infection is the result of the development in the body during the course of the infection of a specific ferment which immediately destroys the infection on renewed exposure; (11) immunity established by vaccination is similar to that induced by an attack of the disease; (12) protein sensitization and bacterial immunity, apparently antipodal, are in reality identical; (13) protein sensitization consists in developing in the animal body a specific proteolytic ferment which digests the same protein on reinjection; (14) when a foreign protein is introduced into the blood of an animal it soon leaves the circulating fluid and is distributed throughout the tissues; (15) vaccines are protein sensitizers; (16) toxin immunity and bacterial immunity are radically different; (17) the protein poison is not a toxin; (18) the protein poison is not specific; (19) the tolerance which may be secured by the protein poison is not specific; (20) the sensitization developed by a protein is specific, but is not due to the poisonous group in the protein; (21) different proteins find in the body certain predilection places in which they are most prone to accumulate; (22) the symptoms of a given disease are largely determined by the location of the foreign protein; (23) the poison elaborated in all the infectious diseases is the same; and (24) when a cell in the animal body is permeated by a foreign protein, the former strives to elaborate a ferment by which the latter is destroyed.

The remaining chapters deal with the growth of massive cultures of bacteria; the chemistry of bacterial cellular substances; the cleavage of proteins with dilute alkali in solution in absolute alcohol; action on animals; the production of active immunity with the split products of the colon bacillus; the split products of the tubercle bacillus and their effects on animals; the anthrax protein; the cellular substance of the pneumococcus; protein sensitization; parenteral digestion; protein fever; specific ferments of the cancer cell; and the phenomena of infection.

The carbohydrate metabolism and the internal secretion, P. HÖCKENDORF (*Der Kohlehydratstoffwechsel und die innere Sekretion. Berlin, 1912, pp. 126*).—This book deals with the interrelationships of the various internal secretions and discusses, on the basis of the newer findings, the part played by these secretions in the diseases of metabolism.

A further study of the distribution of prussic acid in the flax plant, J. W. INCE (*North Dakota Sta. Bul. 106, pp. 30-46*).—This is a report of further investigations (E. S. R., 28, p. 477) of the poisonous principle contained in the flax plant. Analyses of about 80 samples of flax straw, chaff, screenings, the entire flax plant, and young flax for the seasons of 1911 and 1912 are reported with notes upon the character of the samples, with special reference to the percentage of prussic acid present. Some experiences of other experiment station workers and farmers in regard to the toxic action of flax products are cited.

The author finds that all flax materials evidently contain some of the poison, which varies with the stage of maturity of the flax, the part of the plant, and the species of flax, and also with some external conditions, such as weathering.

“While this poison in flax substances may not always become liberated and active enough to be fatal to animals who eat it, nevertheless it is necessary for

farmers to remember the possibility of fatal results, and feed only small quantities of the material until they are certain it will not kill their stock."

Veterinary notes, T. W. CAVE (*Jour. Southeast. Agr. Col. Wye, 1912, No. 21, pp. 439-453*).—These notes relate to struck sheep experiments; parasitic pneumonia of sheep due to the red lungworm (*Strongylus rufescens*), a disease allied to "husk," which is caused by the lung threadworm (*Eustrongylus filaria*); parasites of the fourth stomach of cattle; tuberculosis in cattle and the new tuberculosis order; and the death of fowls from impaction of the crop, due to improper feeding.

The behavior of new serum and liver substances, and levulosuria in trypanosomiasis, K. SCHERN (*Berlin. Tierärztl. Wchnschr., 29 (1913), No. 40, pp. 710, 711*).—Continuing previous work,^a the author sought to determine whether the substances capable of reviving or extending the life of trypanosomes, such as exist in normal serum, were present in other parts of the normal animal organism. Very labile trypanosomes, taken at the third stage of the infection, were treated with organ pastes.

Liver and serum were found to have an elective position in this regard. These substances were found to be very stabile so far as boiling and drying were concerned, and they could be preserved for a long time in a refrigerator at a temperature of 37° C. The activities of this substance or substances are suppressed by putrefaction.

From the liver and serum a substance was prepared in which the reviving and life-extending principles were present in concentrated form, and which after a period of 4 years was still active. Although these principles are present in the serum and liver of diseased animals, they seem to diminish toward the end of the disease. They are absent in the sera of rats in the third stage of the disease. The fresh liver of a rat which died from trypanosomiasis contained the active principle only in a minimum quantity. The possible relation of this principle in other diseases, as glanders, tuberculosis, anthrax, typhoid, and cholera, is also discussed.

Some intraperitoneal injection tests with levulose showed that infected rats in the third stage of the disease will discharge the levulose with the urine. Animals in the first and second stages of the disease did not eliminate levulose.

Tuberculous contagion by dried particles, P. CHAUSSE (*Rec. Méd. Vét., 90 (1913), No. 15, pp. 497-511*).—This deals with the history of the subject and criticizes Cornet's theory. It discusses especially tuberculosis caused by inhalation.

About the intracutaneous use of avian tuberculin for diagnosing fowl tuberculosis, L. VAN ES (*Ztschr. Infektionskrank. u. Hyg. Haustiere, 14 (1913), No. 4-5, pp. 271-296, pl. 1, figs. 2*).—Tuberculosis was noted among the poultry of the North Dakota Experiment Station, and it was decided to study the intracutaneous test as to its value for diagnosing tuberculosis in birds. The tuberculin employed was prepared in the usual manner from the avian tubercle bacillus and was used in a concentration of 50 per cent. In a few cases 100 per cent crude tuberculin was used but as it apparently gave weak reactions, its use was discontinued. The points of application were the comb and one of the wattles, and the injections were given as superficially as possible in order to reach the Malpighian layer. A Pravaz syringe having a small-bore needle was employed for the injections, and the amount of tuberculin given varied from $\frac{1}{2}$ to $\frac{3}{4}$ cc. of 50 per cent tuberculin per fowl.

It is stated that the results can be noted within 24 to 72 hours, but usually 48 hours post-injection. The diagnostic feature consists in noting the swelling

^aArb. K. Gsndhtsamt., 38 (1911), No. 3, pp. 338-367.

at the point of injection, and just as in mammals the typical reaction is one of varying degrees of intensity. The reactions were never accompanied by hyperemic manifestations. The center of the reacting focus of the comb usually is of a pale yellow color and the secondary area is dirty red brown and sometimes greenish. The swelling of the comb is compact while that of the wattles is usually edematous. In the latter the color varies between a dirty pale yellow and a dirty green. The reaction occurs most frequently in the wattles and where comparison was possible a reaction on the comb only was noted in 4.25 per cent of the cases, on the wattles in only 21.25 and on both in 74.5 per cent.

In all there were about 320 birds examined, some of which received tuberculin only once and others twice. Some of the birds came from flocks which were apparently free of tuberculosis. Of all the birds examined 207 were submitted to autopsy, and 108 of these were found to be tuberculous. Among 75 which gave typical reactions, 73 showed lesions. The number of nonreacting birds was 79, and of these 8 showed lesions. The birds with doubtful or minor reactions were 53 in number, and 27 of these were found to have lesions.

These findings, according to the author, show that the intracutaneous application of avian tuberculin is an almost certain method of diagnosing this disease. The doubtful reactions which occur may limit the usefulness of the test somewhat, although it was ascertained that in such cases one-half of the birds so reacting were found to be tuberculous. This aspect of the problem will, however, be studied further, especially with reference to the kind of tuberculin preparation used. The intracutaneous test probably will have its greatest usefulness in detecting the presence of tuberculosis in a given flock or as a means for guarding against the introduction of tuberculous birds.

The eye test was used in 50 instances with negative results. Many of the birds which were submitted to this test gave a positive intracutaneous reaction.

Tuberculin in diagnosis and treatment, BANDELIER and ROEPKE, trans. by W. B. CHRISTOPHERSON (*New York, 1913, 2. ed., pp. XVI+307, pls. 9, figs. 5*).—This text-book on the specific diagnosis and therapy of tuberculosis is in its second English edition and translated from the seventh revised and enlarged German edition. It is divided into the following sections: Theories of tuberculin reaction and the curative factors of tuberculin action; the specific diagnosis and the specific treatment of tuberculosis (chiefly from the human medical standpoint); and a special section which takes up pulmonary tuberculosis and tuberculosis of the respiratory tract, digestive organs, urogenital organs, serous membranes, eye, ear, skin, glands, bones, and joints. It also contains 25 temperature charts, 2 colored lithographic plates, 5 illustrations, and a bibliography.

Bovine tuberculosis in man, R. S. WILLIAMS (*Reading Univ. Col. Rev., 5 (1913), No. 15, pp. 217-230*).—The work of Robert Koch in regard to the transmission of tuberculosis from animal to man is reviewed, and is followed by the opinions of O. Bang, Sims Woodhead, Park and Krumwiede, Fraser, and Delépine. The conclusion reached is that bovine tuberculosis can be conveyed to man.

[Circular letter of the Board of Agriculture and Fisheries of Great Britain as to tuberculosis], S. OLIVIER (*Jour. Bd. Agr. [London], 19 (1913), No. 12, pp. 1043-1046*).—This deals with the measures recommended for the eradication of the tuberculous cow. It aims at the destruction of every cow found to be suffering from tuberculosis of the udder or discharging tubercle bacilli with the milk, and all bovines which are suffering from tuberculosis with emaciation. When tuberculosis is not detected in the animal after slaughter, its owner is to be reimbursed for the full value of the animal plus 20 shillings. "Where tuberculosis is found the proportion of the value of the animal payable by way

of compensation to the owner is made to depend upon the extent of the disease which is present."

The combating of bovine tuberculosis on the basis of mutuality, MOREY (*Rev. Gén. Méd. Vét.*, 21 (1913), No. 247, pp. 365-395).—A discussion in regard to tuberculosis as it exists among dairy and other animals in the districts of Charolles, Autun, Châlons-sur-Saône, Louhans, and Mâcon. The author proposes to eradicate tuberculosis by a mutual process, which is to include the activities of both the society of owners of the cattle and the State. The tuberculin test is to be used with a system of marking the tuberculous animals, marks which resemble the Murphy button used in intestinal surgery being placed on the left ear of the animal. The cost of eradicating the disease on a mutual basis is discussed.

Tuberculosis in goats, M. SCHLEGEL (*Ztschr. Tiermed.*, 17 (1913), No. 8, pp. 347-349; *abs. in Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 39, pp. 695, 696).—A description of two cases.

In one case the right lung showed pale yellow cheesy-calcified nodules ranging in size from a pinhead to a bean. The left lung showed large gray foci which when cut through showed a whitish yellow, creamlike, smeary mass inclosed in a gray white capsule. The trachea was filled with a slimy purulent secretion in which tubercle bacilli could be easily detected. The enlarged bronchial and mediastinal lymph glands also contained tubercle bacilli.

The other case represented a high grade of generalized tuberculosis of the lungs, liver, and kidneys. This animal was 7 years old and very cachectic. The bovine type of bacillus was noted in this case.

A preliminary report on the investigations of bovine redwater (cystic hematuria) in Washington, J. W. KALKUS (*Washington Sta. Bul.* 112, pp. 27, pls. 10).—This report is based upon investigations commenced by the station in 1908. The results have been summarized by the author as follows: "Redwater is a specific disease of cattle and is quite common in the western part of Washington. It is characterized clinically by the constant or periodic discharge of bloody urine and by its chronic course; and pathologically by the characteristic vascular lesions which occur on the bladder mucosa. The cause of the disease is yet to be discovered.

"Blood of sick cows seems to be innocuous to healthy ones. The disease has been apparently transmitted from a sick to a healthy cow by inoculation of the latter with the bladder lesions of the former. Although some drugs seem to render temporary relief, treatment as a whole has been very unsatisfactory. Permanent recoveries from redwater are doubtful; a cow once affected with the disease nearly always eventually succumbs to it."

Studies on hog cholera.—*Spirochæta suis*, its significance as a pathogenic organism, W. E. KING and G. L. HOFFMANN (*Jour. Infect. Diseases*, 13 (1913), No. 3, pp. 463-498, pl. 1, figs. 44).—Continuing the work already noted (E. S. R., 29, p. 681) the authors now report that *S. suis* is found in the intestinal ulcers, crypts in the ceca, and in the external local lesions of animals suffering from hog cholera. The spirochete resembles in many respects *S. pallida*, *S. gallinarum*, and other forms, and appears to be capable of breaking up into granules. These granules, the authors believe, may play an important part in the life cycle and physiological functions of the spirochete, as suggested by the notes of Fontes on tuberculosis (E. S. R., 27, p. 285). They are present in the blood of cholera hogs, and in cultures of *S. suis*, and are capable of producing the disease in healthy hogs.

"In the blood of hogs suffering from cholera the presence of a relatively large spirochete in few numbers has been recognized. As this organism has not been found in the blood of normal hogs, it may represent *S. suis* in a tran-

sitional form. Its morphological variation from *S. suis*, as found in ulcers and local foci, may be due to the unfavorable action of blood as a medium or to its natural processes as a part of the life cycle of the species.

"*S. suis* is an obligatory anaerobic organism and usually requires several weeks' incubation for growth to take place on artificial culture medium. It may be transferred from generation to generation on artificial culture medium. Cultures containing the organism in the form of granules and spirochetes may be passed through bacteria-proof filters and the spirochetes removed, the few small granules which pass through being capable of producing hog cholera or resistance to the disease.

"*S. suis* is capable of producing typical hog cholera when injected into healthy hogs. This is true not alone of contaminated cultures made directly from the intestinal ulcers of cholera hogs; second and third generations on artificial culture media, containing the *S. suis*, as well as the Berkfeld filtrates of the same transfers, are capable of producing hog cholera and marked reactions, which confer more or less protection against the disease. The pathogenicity of these cultures does not appear to be due to the passage of an unknown 'invisible micro-organism' which is finally transmitted to healthy hogs by inoculation. Control experiments tend to show that the pathogenicity of the cultures of *S. suis* is due to the species itself in the form of spirochetes or granules.

"Finally, in those hogs which received the disease from cultures of *S. suis*, the organism is present in the intestinal lesions or local external lesions, as demonstrated by the dark field examination.

"As the above results have practically fulfilled Koch's laws, in so far as it is possible with an organism possessing the biological characteristics of spirochetes, [the authors believe] it may logically be concluded that *S. suis* is more nearly established as the specific cause of hog cholera than any other known organism."

Cultivating the virus of hog cholera, W. PFEILER and W. LENTZ (*Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 39, pp. 689-692).—The virus used in these experiments was obtained from the organs of infected hogs, and filtered in order to render it sterile so far as visible organisms were concerned. A loopful was then tested with regard to its infectivity and another loopful was sown on a nutrient medium. In most cases no hog cholera was produced before cultivation in the medium. After cultivation a loopful of the culture was transferred into another flask containing nutrient medium and at the same time a loopful or a fraction thereof was given subcutaneously to shoats. The cultures were transplanted in the manner described until a dilution corresponding to 1:200,000,000 loopfuls was obtained. In most cases hog cholera was produced with every dilution (after cultivation) and almost every form of the disease could be noted.

It was also possible to cause the disease with an organ filtrate of the animals infected with the cultivated virus, and in some instances infection was produced by simple cohabitation and by feeding a 1:100,000,000 dilution.

A note on kidney worm infestation of swine as shown post-mortem at the Manila matadero, R. W. NEWCOMB (*Philippine Agr. Rev. [English Ed.]*, 6 (1913), No. 8, pp. 399, 400).—An investigation was made by the author of the occurrence of *Stephanurus dentatus* in native hogs killed at the Manila matadero, which at the same time permitted the gathering of information regarding its distribution in the southern part of central Luzon. In all some 2,000 hogs were examined and nearly 50 per cent found to be infested.

"The parasites are most commonly found in the fatty tissue posterior to the kidneys, though they may be found in the hilum of the kidney or even in the

kidney tissue itself, and occasionally in the mesenteric fat, the psoas muscles, and the neck of the bladder. Tubular tracts are formed of hard connective tissue sometimes as large as a pencil, and having very thick walls. Often a sort of nest is formed, composed of many convolutions of a single tube or of several of the tracts combined. These nests are often 2 or 3 in. (50 or 76 mm.) in diameter. When found in the kidney tissue the parasites are usually very small. They cause destruction of portions of the kidney with a subsequent formation of scar tissue which upon contraction distorts the surface of the kidney to a marked degree, so that it is often possible to detect an infested kidney by its exterior appearance. . . . Adhesions of the intestines to adjacent organs or other parts of the intestines are rarely found and very rarely an acute peritonitis due to perforation of the intestines or kidney."

606 in the treatment of the pectoral form of equine influenza, C. HÉBRAY (*Rev. Gén. Méd. Vét.*, 22 (1913), No. 255-256, pp. 113-117).—The author reports upon a case of this disease in a 5-year-old horse which on the sixth day developed serious complications, including double pneumonia and laminitis. The intravenous injection at this time of 2 gm. of arsenobenzol in 30 gm. of physiologic serum resulted in a rapid and complete recovery. The author considers the use of arsenobenzol in this disease to be more economical than are other medications usually administered, especially if the use of the horse is considered.

Autoserotherapy in veterinary ophthalmology, PRUNEAU (*Rec. Méd. Vét.*, 90 (1913), No. 19, pp. 640, 641).—A description of a case of pseudomembranous conjunctivitis in a mare which was treated successfully by autoserotherapy. The method of treatment consisted of introducing an appropriately prepared serum (blood from a vein), into the conjunctival sack. The eyes were also washed with serum after anesthetizing with a 4 per cent cocaine solution.

Autoserotherapy for treating exudative pleurisy, U. MELLO (*Mod. Zoiatro.*, *Parte Sci.*, 1913, No. 8, pp. 303-316).—A description of 5 cases in horses successfully treated by this method.

Bacillus typhi gallinarum alcalifaciens and the disease which it causes in fowls, W. PFELLER and A. REHSE (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg*, 5 (1913), No. 4, pp. 306-321; *abs. in Berlin. Tierärztl. Wehnschr.*, 29 (1913), No. 24, p. 439).—The authors report studies made during the course of two outbreaks of disease among fowls. In serological and cultural studies the bacilli isolated were found to resemble the typhoid bacillus (*B. typhosus*). The organism was extremely virulent for chickens but ducks, geese, and pigeons were resistant to its action.

The paper includes a review of the literature and a bibliography of 17 titles.

RURAL ENGINEERING.

Obtaining ground water supplies by pumping, A. A. MEYERS (*Arch. Suiker-indus. Nederland. Indië*, 21 (1913), No. 29, pp. 906-942, pls. 4).—Methods of obtaining ground water for irrigation are discussed, dealing first with the sinking of deep and shallow wells, well casings, filters, etc., and second with deep and shallow well pumping machinery and both steam and electrical pumping power.

Data on pumping plants in different localities show a wide range of efficiencies. Attention is called to different irrigation districts to which pumping power is supplied from central stations.

A number of drawings and illustrations of pumping machinery and well equipment accompany the article.

Conservation and distribution of water for irrigation (*New York* [1913], pp. 77, figs. 62).—Applications of pumping machinery for irrigation are illus-

trated and described, and considerable data are given to be used in pumping, measuring, and distributing irrigation water.

The rating of current meters, J. B. BROWN (*Engin. News*, 70 (1913), No. 15, pp. 712-714, figs. 4).—This article describes the process of rating current meters used by a water company selling irrigation water by current meter measurement (E. S. R., 28, p. 889). The rating station consists of a concrete lined flume 175 ft. long over which a car driven by a variable speed motor is operated. Ten observations are taken with each meter at speeds approximating $\frac{1}{2}$, 1, $1\frac{1}{2}$, and 3 ft. per second. The observations recorded are number of revolutions of the meter, distance traveled, and time in seconds for each run. Revolutions per second and the corresponding velocities in feet per second are computed and rigorously adjusted, and from these results a rating curve is plotted.

Sample observations, computations, and the resulting curve are given, with formulas for computing and adjusting results.

Summary and report on the first subsoil blasting demonstrations in Trinidad, 1913, H. VINCENT (*Proc. Agr. Soc. Trinidad and Tobago*, 13 (1913), No. 9, pp. 449-454).—Experiments were conducted in the blasting of water-logged subsoils covering 11 districts of Trinidad, 8 of which possessed an extremely tenacious clay subsoil. About 15 acres altogether were blasted and 10 cases of dynamite cartridges were used. The summary of data given in tabular form shows that the depth of charge varied from 1 ft. 6 in. to 4 ft. and the spacing of holes from 8 to 24 ft.

From the results of the experiments the advantages of blasting water-logged lands are summarized, including the improved aeration of the soil, the decreasing of surface wash, the better incorporation of the plant food in manures, an increased solvent action from rain water, and an improved porosity in stiff clays, with consequent greater root depth and drought resistance.

Object-lesson and experimental roads, and bridge construction, 1912-13 (U. S. Dept. Agr. Bul. 53, pp. 34).—This bulletin describes in detail the construction of object-lesson roads during the past fiscal year, including one each of bituminous-concrete, bituminous-macadam, gravel-macadam, brick-cinder, and sand-gumbo roads, 3 shell roads, 4 gravel roads, 7 macadam roads, 9 earth roads, and 14 sand-clay roads. The total area of object-lesson roads showed an increase from 79,203 sq. yds. in 1905 to 488,331 sq. yds. in 1913.

In addition reports are given of bridge work and inspection of object-lesson roads, a report of work on the Memphis to Bristol Highway, and a brief account of experimental work for the year, which is to be reported in detail later.

Concrete roads and pavements, E. S. HANSON (*Chicago*, 1913, pp. 227, figs. 29).—It is the purpose of this book not only to stimulate the construction of concrete roadways but also to furnish road makers specific data from the experience of others. The matter is presented under the following chapters: Concrete as a road material; the construction of concrete roadways; the roads of Wayne County, Michigan; cost of concrete roads in Illinois; other examples of concrete roads; some data on city pavements; reinforced concrete pavements; concrete in combination with other materials; patented concrete pavements; the theory and practice of joints; some tests of concrete as a roadway material; bridges and culverts; sidewalks, curbs, and gutters.

Specifications for concrete roads and pavements from various sources are appended.

Concrete pavement troubles (*Cement World*, 7 (1913), No. 7, pp. 46-48, figs. 3).—Data and photographs are given relating to the causes operative in numerous examples of failure observed in concrete roads and pavements, covering a wide range of local conditions. Failures are attributed chiefly to

unscientific design, lack of rolling, incorrect proportions, improper materials or their defective preparation, mixing or careless placing, improper finish of wearing surface, faulty joints, neglect of protection, inadequate curing, and inspection.

Tests of concrete and brick pavements (*Engin. Rec.*, 68 (1913), No. 17, pp. 457, 458, figs. 4).—Tests were made on concrete and brick pavements by means of a so-called "determinator" designed by the department of public works of Detroit. A test space 40 ft. square was divided as follows: In half of the space a 1:1½:3 gravel concrete pavement was laid, in one-fourth of the remaining space crushed granite concrete, and in the remaining space a brick pavement composed of two sections similar in all respects except that one had a 1:5 mortar cushion and the other an ordinary sand cushion.

The determinator consists essentially of a central vertical column or pivot around which revolves a horizontal shafting having heavy cast-iron wheels on each end 48 in. in diameter with rims 3 in. wide. The weight transmitted to the floor by each wheel is 1,650 lbs. To reproduce the wear due to rough shod horses each wheel is provided with 5 plungers on the ends of which are metal plates having 4 steel calks. As the wheels revolve, these plates strike the surface of the pavement a heavy blow, estimated in this test at 150 lbs.

After 19,315 revolutions of the machine the gravel concrete had worn badly and unevenly, as much as 1½ in. in places, while the granite concrete showed only little wear and that very even. The brick section laid on a mortar cushion was in excellent condition while that on the sand cushion was beginning to disintegrate.

The use of mechanical power in German agricultural work, II. K. SCHWAN-ECHE (*Fühling's Landw. Ztg.*, 62 (1913), Nos. 2, pp. 41-65; 3, pp. 95-108, figs. 3; 7, pp. 242-272; 8, pp. 286-306; 12, pp. 426-443).—This article deals at length with the comparative efficiencies and economies of the various forms of power used in German agricultural work. The investigations are grouped under 3 heads: (1) Small power up to 15 h. p. for belt work confined to the farm yard. (2) power for heavier field machinery and for transportation, and (3) electric power plants and central power plants.

For work confined to the farm yard and requiring up to 15 h. p. it is concluded that wind power, when available, may be profitably used in spite of the high initial cost of the plant. In case wind power is not available and where an all-purpose power from 8 to 15 h. p. is desired, the small portable steam engine is concluded to be the most practical and economical if the engine operator can be profitably employed at other work when the engine is not in use. For smaller belt work the internal combustion engine may be profitably employed and also the electric motor, providing the price for electric current does not exceed 15 pfennigs (3¼ cts) per horsepower hour. Steam power is concluded to be in general the most efficient and economical power for the heavy field work of plowing, threshing, etc., where several related operations are combined into one operation.

A comparison of motor trucks and horses for transportation purposes indicates that the former may be used with economy only in case special apparatus for loading and unloading is used and where the truck is used at least 70 or 80 days a year, carrying a full load on an average of not less than 30 km. (18.6 miles) daily. The use of motor trucks is concluded to be uneconomical for farms smaller than 375 to 500 acres.

The article further considers small private electric power plants and central power plants, giving information regarding the installation and operation of the former and data on the cost of power from both.

Internal combustion motors in agriculture, NEUMANN ET AL. (*Jahrb. Deut. Landw. Gesell.*, 28 (1913), No. 1, pp. 205-222, figs. 25).—This article deals with the use in agricultural belt work of several types of small internal combustion motors using gasoline, oil, and naphthalin as fuel.

Curves showing the comparative costs of power per horsepower hour from various sizes of internal combustion motors and corresponding sizes of electric motors indicate that electric power for small farm belt work is the cheaper only when used a small number of working hours per year, while the cost of internal combustion power decreases gradually as the number of working hours per year increases from 1,000 to 2,000. This condition exists up to 16 h. p. when the curves show that steam power is a little cheaper than internal combustion power at 2,000 working hours per year. The cost of these two is equal at about 1,400 hours per year.

Rural lighting and motor service near Noblesville, Ind. (*Elect. World*, 62 (1913), No. 15, pp. 749, 750, figs. 5).—This article calls attention to a rural electric transmission system in Indiana supplying electric light and power to 100 strictly farm customers from a central station in a neighboring town. The farm lines are operated at 2,200 volts, single phase service, and the company estimates that at least four customers must be served per mile to make the line commercially profitable. The rates for service are 10 cts. per kilowatt hour, subject to a 5 per cent discount, with a minimum quarterly rate of \$1.50. Each farmer furnishes his own equipment, including transformer and wiring, poles, etc. from the main line. He also pays for a proportional share of the main line which is repaid in service at the stated rates.

Test of a nominal 10 h. p. benzin locomotive, J. REZEK (*Mitt. Landw. Lehrkanz. K. K. Hochsch. Bodenkul. Wien*, 1 (1913), No. 3, pp. 407-409, pl. 1).—A portable 4-cycle single cylinder internal combustion motor having a 180 mm. (7 in.) bore and a 260 mm. (10 in.) stroke, rated at 10 h. p., was tested under variable load and speed conditions using benzin as fuel. The fuel consumption per horsepower hour was in general found to decrease and the mechanical efficiency was found to increase as the load increased up to the rated capacity. Mechanical efficiencies of from 52 to 82 per cent were obtained.

The economy of motor trucks with special reference to agricultural conditions, E. JAENICHEN (*Maschinen Ztg.*, 11 (1913), No. 17, pp. 201-209, figs. 8).—Numerous data from actual experience with the use of motor trucks and horses for agricultural transportation purposes demonstrate the superiority of the former in both efficiency and economy. The data in all cases extend over a year's work and include initial cost, depreciation, interest, and cost of operation. The high initial cost of the truck is offset by its overwhelming advantages of speed, convenience of concentrated power, high loading capacity, and indifference to weather conditions and fatigue. The initial cost and cost of keeping a number of horses of power equivalent to the average truck, it is stated, exceed the initial cost and cost of operation and maintenance of the truck.

The first "stock" motor plow in Africa, H. VON NATHUSIUS (*Pflanzer*, 9 (1913), No. 6, pp. 283-287, pls. 4).—Plowing tests were conducted in hard packed sandy loam with a "stock" motor plow on which only 3 of the 6 shares were used. The average speed was about 3.7 ft. per second, the average depth of furrow about 8.6 in., and the average width of furrow about 13 in. An average of about 7.5 acres was plowed in 10 hours. The total cost per acre of the work, including interest on the investment and depreciation, was about \$4.35. Cost figures from a year's work, using 3 and 4 shares, show a total average cost per

acre of about \$3.70. These results are deemed not at all discouraging when the price of fuel and the unfavorable conditions of soil and weather are considered.

The advantages stated for this motor plow are that it is not affected by weather or weeds and saves high-priced labor. It is stated, however, that considerable changes must be made in the apparatus before satisfactory results can be obtained in the seeding and cultivation of cotton soils.

A new steam plow dynamometer, J. REZEK (*Mitt. Landw. Lehrkanz. K. K. Hochsch. Bodenkul. Wien*, 1 (1913), No. 3, pp. 393-406, pl. 1).—A new dynamometer for measuring the tractive effort of steam tractors is described which consists essentially of an oil-filled cylinder connected to the plow or other load and a piston in the cylinder connected to the drawbar of the tractor. The resulting oil pressure in the cylinder is transmitted to a revolving drum above, which registers the distance traveled and the corresponding tractive effort.

Service tests of this dynamometer and comparisons with other types serve to show its accuracy in recording minute variations in the tractive effort. It has the disadvantage, however, that the oil is likely to leak out of the cylinder, and must be watched in this respect.

Stock watering devices in lowland pastures, J. HEISIG (*Ztschr. Moorkultur u. Torfverwert.*, 11 (1913), No. 3, pp. 87-93, figs. 3).—Cheap and serviceable methods of watering stock in lowland pastures are described, including structures for storing water from wells, brooks, and springs.

Silos, construction and service, M. L. KING (*Ext. Publ. Minn.*, 1913, pp. 100, figs. 31).—This book takes up the fundamentals of silage preservation, describes different types of wood and masonry silos, and explains the details and the construction of what are considered the more important types, under the following chapters: Early development, fundamentals of silage preservation, wood silos, masonry silos, planning the silo, erection of stave silos, monolithic concrete silos, the Iowa system of building block silos, safe strength of materials, and buying and contracting for silos.

A study of the hog house question, PROBST (*Illus. Landw. Ztg.*, 33 (1913), No. 59, pp. 539-541, figs. 6).—This article deals with the design of hog houses, emphasizing, in addition to cost, warmth, dryness, ventilation, and sunlight as the essential considerations.

Studies in poultry house construction, H. R. LEWIS and A. L. CLARK (*New Jersey Stas. Rpt.* 1912, pp. 104-124, pls. 10, figs. 7).—This article reports studies of 5 types of poultry houses erected at the station plant during the fall and winter of 1911-12, and gives data in regard to cost and environmental conditions as they existed during the winter, including studies of temperature and moisture conditions.

The results of these studies point to the following conclusions: "(1) A house with a large area of glass and no muslin has a high moisture content and low temperature, accompanied with rapid changes. (2) An extreme open front house furnishes ideal conditions, providing the birds are protected from rain, snow, and drafts. (3) A house, the front of which contains some muslin and glass, is a very efficient type. . . . (4) Hollow tile construction makes a very desirable house, but it is doubtful whether at the present prices of tile and mason labor the resulting increased cost warrants its use. (5) A roosting closet with double walls is desirable in shed roof laying houses. (6) The providing of ample means of properly ventilating shed roof, paper covered houses adds greatly in reducing temperature during spring and summer. (7) Tongued and grooved boards for the outside walls when covered with a layer of building paper are reasonable in cost and supply in a great measure the nonradiating qualities of a double wood wall."

As a result of this study, a new type of house was evolved called the New Jersey Multiple Unit Laying House, which is described in detail. Studies of this type are to be reported in a later bulletin.

Housing farm poultry, B. ADLER (*Utah Sta. Circ. 14*, pp. 15-32, figs. 9).—This circular discusses some of the essentials of a good poultry house for Utah conditions and offers detailed plans and bills of material for three houses in which an attempt has been made to include these essentials.

One room school buildings (*Penn. Bd. Ed. Prelim. Bul., 1913*, pp. 13, pls. 10).—This bulletin presents suggestive standard plans and limited specifications for the construction of one-room school buildings for rural and suburban districts. These plans and specifications are said to conform to the modern principles of lighting, heating, ventilation, and physical activity.

The necessity of plumbing inspection in rural districts, W. C. GROENIGER (*Mo. Bul. Ohio Bd. Health, 3* (1913), No. 10, pp. 900-906).—This article deals with rural sanitation, considering briefly the subjects of water supply and sewage disposal and making a few suggestions regarding the proper installation and testing of plumbing. Attention is called to the many sources of pollution of water supplies and the reader is particularly warned against locating the so-called water-tight cesspool in the immediate neighborhood of wells or springs.

Bacteriological tests of methods of cleaning, W. D. FROST and Miss V. A. ARMSTRONG (*Addresses and Proc. Nat. Ed. Assoc., 49* (1911), pp. 985-990).—Studies of the relative number of bacteria present when floors are cleaned by different methods are reported, the experimental method followed being described.

In connection with vacuum cleaners, the authors note that with permanently installed systems bacteria are taken out of the rooms entirely, and, if the discharge pipe is properly located, do not return to the rooms. With portable cleaners, however, which discharge into the room, the larger or smaller number of bacteria pass from the container into the room, the number depending upon the kind of construction of the container, "hence they may be an actual menace to health. It is possible to obtain abundant data to warrant health officers forbidding the use of these machines by traveling cleaners, since it must be very evident that if *Bacillus prodigiosus* can be carried from one room to another, *B. tuberculosis* could be carried from one house to another."

RURAL ECONOMICS.

Our rural life and farm problems, S. A. LINDSEY (*U. S. Senate, 63. Cong., 2. Sess., Doc. 334, 1913*, pp. 3-17).—The rural life problems as seen by the author are principally due to the increase in tenantry, high rate of interest to farmers, and wasteful methods of distributing farm crops. To overcome these obstacles he suggests cooperation among farmers, rural credit, better transportation facilities, and better rural homes and schools.

How can a young man become a farmer, T. F. HUNT (*Berkeley, Cal.: Univ. Cal. [1913]*, pp. 8).—The author considers that one of the factors in keeping young men from becoming farm owners is the difficulty in obtaining the necessary capital. He suggests that postal savings deposits be lent to him at 3 per cent and the debt be cancelled by a system of amortization.

The needs of North Carolina farmers with regard to credits, marketing, and cooperation (*Rpt. Com. Appointed by Gov. N. C. on Needs N. C. Farmers, 1913*, pp. 13).—The commission announces as the principal need of the North Carolina farmer a modification of the European system of credit adapted to American conditions, so that a worthy citizen can buy land, drain it, and stock it properly.

It is stated that because of the undeveloped marketing system in North Carolina there is imported annually \$50,000,000 worth of food and feed products which should be produced in the State. Proper standardization is needed in order to market profitably the farmer's products. The belief is expressed that the farmer must bring about these results through his own efforts, but under the guidance of the State.

Cooperation in Brazil (*Relat. Min. Agr. Indus., e Com., Brazil, 1911, No. 3, pp. 133-200*).—This article traces the cooperative movement in Brazil from its beginning in 1819 by the formation of a society of agriculture, commerce, and navigation to the present time. It describes in considerable detail the different forms of organization and their adaptation to special industries, such as sugar and coffee production, agricultural credit, etc.

Report on the working of the cooperative societies in the Punjab for the year ending July 31, 1913, A. LANGLEY (*Rpt. Work. Coop. Soes. Punjab, 1913, pp. 3+2+11, tables 14*).—This report shows the workings of the societies for the fiscal year 1913, calling attention to the rapid expansion of the movement among the agricultural classes and to the fact that the opposition of the money lender is gradually being overcome. Statistics are given showing membership, receipts and disbursements, etc., for the central, agricultural, and nonagricultural societies.

Early associations for promoting agriculture and improving the improver, T. H. MIDDLETON (*Rpt. Brit. Assoc. Adv. Sci., 1912, pp. 709-730*).—The author sketches the various agencies that have been effective in improving British agriculture from 1860 to date.

Agricultural accident insurance in the Netherlands, E. VAN DER FEEN-MÜLLER (*Mitt. Deut. Landw. Gesell., 28 (1913), No. 40, pp. 555-558*).—This article traces the causes leading up to accident insurance associations for agricultural workers, describes the organizations, and gives considerable information concerning the number insured and the cost.

[Dairy farm management], D. H. OTIS (*Hoard's Dairyman, 46 (1913), Nos. 3, p. 52; 12, pp. 319, 329, 330*).—The first of these articles gives in detail the investment and income from the various kinds of live stock on two farms of approximately the same size, and points out that one farm made a much better profit than the other because of a better understanding of market conditions and of advertising.

In the second article a review and discussion is given of the managerial methods of two dairy farms, substantially alike, but one of which realizes an income of \$4,232.20, the other \$851.66. The author ascribes the greater profits of the former to the returns from larger sales and the increased inventory of equipment and live stock, particularly dairy cattle. It is deemed noteworthy that although this farm has the lower total capitalization, it has considerably more investment in pure-bred stock and equipment.

Statistical study of wheat cultivation and trade, 1881-1910, J. F. UNSTEAD (*Geogr. Jour., 42 (1913), Nos. 2, pp. 165-181, figs. 2; 3, pp. 254-276*).—By a study of the area, production, and trade in wheat for practically all the countries of the world the author comes to the conclusion that there has been an increase of about 300,000,000 bu. for the period of 1891-1900 over that of 1881-1890, and one of 700,000,000 bu. for 1901-1910 over 1891-1900. This increase was due mostly to increased acreage, but to some extent to increased average yield per acre.

The study also leads to the conclusion that the acreage may be considerably extended and a higher return per acre may be expected.

The following table shows the average yields and per capita consumption as given by the author:

Average yields and per capita consumption of wheat for countries named.

Country.	Yield per acre.			Per capita consumption.		
	1881-1890.	1891-1900.	1901-1910.	1881-1890.	1891-1900.	1901-1910.

^a Estimated.

The agricultural outlook (*U. S. Dept. Agr., Farmers' Bul. 563, pp. 36, fig. 1*).—Notes and tables are given showing estimates of crop yields per acre, prices of staple crops, prices of meat animals, and average and total yield of all crops combined by States, with comparisons. A decrease of about 13.1 per cent in crop yields per acre is estimated as compared with last year, or about 6.3 per cent as compared with the estimated average yields of the last 10 years.

Statistics of agriculture in Russia, P. VON BOETTICHER (*Ztschr. Agrarpolitik, 11 (1913), No. 12, pp. 414-421*).—A detailed statement is given as to the origin of the Central Statistical Committee and the contents of the various statistical reports relating to agriculture issued since 1881.

Agricultural workers in Denmark (*Statist. Aarbog Danmark, 18 (1913), pp. 26-29*).—Statistical tables are given showing for 1911 the number actively engaged (*soutiens*) for all occupations and for agriculture, and the number dependent upon the workers (*soutiens*), i. e., the nonworkers (*nourris*) and the domestic servants.

The number of farms in Denmark (*Statist. Aarbog Danmark, 18 (1913), p. 36*).—The number and area of farms by sizes for 1873, 1885, 1895, and 1905 are given in the form of a statistical table.

The uses of land in Denmark (*Statist. Aarbog Danmark, 18 (1913), pp. 42-52*).—By statistical tables are shown the areas for practically all the crops grown and the production of the principal crops for 1912. The number of the various kinds of live stock and poultry are shown for 1909 by geographical divisions and by sizes of farms. Additional statistics are given showing the average annual production of milk per cow and its fat content.

Agricultural statistics of British India (*Statist. Abs. Brit. India, 47 1903-1912, pp. 124-134*).—Statistical data are given showing the areas under the principal crops for 1902-3 to 1911-12 for British India as a whole, with supplementary data for 1911-12 for the individual administrations. Data are also given regarding cooperative credit societies and rainfall.

AGRICULTURAL EDUCATION.

The work of the rural school, J. D. EGGLESTON and R. W. BRUÈRE (*New York and London, 1913, pp. IX+287, pls. 12*).—This book deals with such subjects as buildings, grounds, sanitation, the centralization of high schools, transportation, plans of instruction, agriculture, amusements, etc. It considers the

school as not an isolated fact, but an essential phase in the upbuilding of the rural community. The importance of the new rural school as an expression of a new movement in rural life is emphasized.

Decree of July 15, 1913, reorganizing the higher council of agriculture in France (*Rev. Vit.*, 20 (1913), No. 1026, pp. 213-215).—The organization and functions of the higher council of agriculture are outlined.

Statistics of education in the Kingdom of Wurttemberg for 1912 (*Statist. Unterr. u. Erziehungsw. Kgr. Wurttemb.*, 1912, pp. 64).—Statistics are presented for the agricultural institutions in the Kingdom of Wurttemberg.

[Agricultural education under the direction of the chamber of agriculture] (*Jahresber. Landw. Kammer Rheinprov.* 1912, pp. 71-93).—This is the annual report of progress in agricultural education under the direction of the chamber of agriculture of the Rhine Province, including the work of scientific and educational institutions, agricultural winter schools, special courses, and itinerant agricultural instruction.

Agricultural winter schools of the chamber of agriculture (*Ztschr. Landw. Kammer Schlesien*, 17 (1913), No. 41, pp. 1512-1514).—The object, organization, and admission requirements of the agricultural winter schools under the direction of the chamber of agriculture of the Province of Silesia are outlined.

How may agricultural instruction be adapted to present needs, M. ARTHOLD (*Wiener Landw. Ztg.*, 63 (1913), No. 83, pp. 939-941).—The author outlines briefly the facilities for agricultural instruction in Lower Austria below the agricultural intermediate school at Mödling, including agricultural technical schools with 1 and 2-year theoretical-practical courses, agricultural winter schools, and housekeeping schools, and discusses the following suggested improvements: (1) That the course of study of these technical schools be revised by representatives of the different kinds of schools, (2) that uniform instruction be issued to teachers, (3) that all schools receive resident students and possess a farm, (4) that the attendance be limited to from 20 to 30 students, (5) that a minimum admission age of 15 years for the 1-year schools and 17 years for the winter schools be required, (6) that a number of stipends of about \$81 be awarded annually for the further training of agricultural technical instructors, and (7) that agricultural teachers who can show more than the required 2 years of practical experience be credited with half of such time when appointed in the state service.

Agricultural education and research (*Rpt. Scot. Agr. Com. Aust.*, 1910-11, pp. 153-172).—This report is not a detailed description of the Australian system, but records the impressions of the Scottish Agricultural Commission for 1910-11 concerning the efforts being made by the various Australian States to develop agricultural education and research.

The high school course in agriculture, J. MAIN (*Addresses and Proc. Nat. Ed. Assoc.*, 50 (1912), pp. 1393-1398).—This paper presents the report of a committee of the National Education Association in which is included a carefully worked out plan for determining the high school course in agriculture in accordance with the requirements of seasonal sequence in relation to the high school sciences. The committee has evidently kept in mind the psychological development of the child, the motive of agriculture in the high school and its correlation with the sciences, the motive of high-school science, the sequences of the sciences and agriculture, and other correlated subjects.

A discussion of the subject follows the report with some suggestions relating to courses of study in agriculture.

Agriculture in the rural schools.—Course of study, B. M. DAVIS (*Addresses and Proc. Nat. Ed. Assoc.*, 50 (1912), pp. 1398-1401).—This report points out

some of the guiding principles to be followed in outlining a course of study in agriculture in the rural schools, suggests units of instruction by groups and grades, and makes other suggestions as to the best methods of giving such instruction and correlating it with various agricultural activities found among patrons of the school.

A minimum course of study in agriculture for rural elementary one-teacher schools located in agricultural communities, R. O. JOHNSON (*Addresses and Proc. Nat. Ed. Assoc.*, 50 (1912), pp. 1401-1413).—This report outlines a course of study in agriculture for rural elementary schools located in agricultural communities, in which the committee has considered the need for a minimum course, what such a course should include, the weakness of the "rotation" course, the adaptation of topics to grades, and the adaptation of the course to schools with a varying number of grades. Suggestions are made as to what should be included in the minimum course and illustrations are given as to the manner in which topics may be worked out.

A schedule of the minimum course in agriculture as planned for the rural and graded schools of Iowa is also submitted, together with suggestive items for a course of home work to receive school credit.

Forestry and the public schools, E. R. JACKSON (*Addresses and Proc. Nat. Ed. Assoc.*, 50 (1912), pp. 1386-1391).—This paper discusses the relation of forestry to agriculture and the influence of forests upon soils, water supply, and the atmosphere of the continent; points out the educational value of the subject when properly taught; and claims that while it should not be introduced into the public schools by supplanting some existing subject it is an essential part of school work that may be used to supplement a number of other subjects.

Rural school gardens differentiated from city school gardens, V. E. KILPATRICK (*Addresses and Proc. Nat. Ed. Assoc.*, 50 (1912), pp. 1377-1379).—The author believes that both rural and city school gardens are justified on the ground that they offer a fundamentally educative material and furnish an interest which arouses the potent forces in the educative process used. The rural school garden aims to idealize agricultural work and improve agricultural methods, dignify farm life, and train the pupil for greater efficiency. The city school garden offers an opportunity for the pupil to work in the open air and sunlight, and while it does not teach him to become a farmer it trains him for citizenship.

The home garden and experimental plats, E. R. DOWNING (*Addresses and Proc. Nat. Ed. Assoc.*, 50 (1912), pp. 1381-1386).—In place of school gardens to be worked and looked after during the school session but allowed to grow up in weeds during vacation, the author advocates the establishment of home gardens and experimental plats in connection with the school, holding that their educational value is equal to that of the school garden and has added advantages in that it establishes normal relations of instruction between parent and child, adds to the economic resources of the family, and enables the school to avail itself of the skill and knowledge of the entire community in the garden instruction.

Suggestions are made as to how such a scheme could be enlarged by holding an agricultural fair at the school in the early fall, at which there should be a competitive exhibition of garden produce, flowers, vegetables, fruits, etc., that have been grown by the children alone or which they have helped to produce or prepare.

Farm crops laboratory material, A. C. ARNY (*Minnesota Sta. Press Bul.* 43, rev. and enl., 1913, pp. 16, figs. 3).—This publication gives a catalogue and price list of exhibits of a number of farm crops which have been prepared by the Minnesota College of Agriculture for sale with a view to overcoming the difficulty

experienced by schools and colleges in securing and keeping properly named specimens.

Elementary tropical agriculture, W. H. JOHNSON (*London, 1913, pp. XI+150, figs. 20*).—While this book is primarily intended for use in connection with the study of the principles of agriculture in schools, it is also considered of service to tropical planters. It is divided into 2 parts, viz, the soil and plant life and the school garden. Chapters consisting of discussions and demonstrations are devoted to the soil, seed, root, stem, leaves, flower, fruit, food of plants, plant diseases, insect pests, school garden, cultivation of various crops, and general cultural instructions.

Course of lessons in domestic science, MYRTLE L. WILSON (*Little Rock, Ark., 1913, pp. 128, figs. 6*).—The composition of food and other similar topics are taken up in connection with recipes.

Woman's congress [and exhibits of interest to housekeepers] (*Mich. Farmers' Insts., Inst. Bul. 19, 1913, pp. 225-275, 277-280, 284-287, figs. 10*).—Among the papers presented were the following: Planting the Home Grounds, by C. P. Halligan; How Can We Solve the Problems of the Farm Home, by Ilena M. Bailey; A Discussion on How to Solve the Problems in the Farm Home, by Mrs. F. D. Saunders; The Roasting of Meats, by Agnes Hunt; Using Sale Patterns, by Ora G. Yenawine; and Cooperation among Women, by Jennie Buell (including data on cooperative laundries).

Domestic science bacteriology formed a part of the bacteriological exhibit, and H. H. Musselman had arranged a household power plant exhibit. Both of these are described in considerable detail.

The organization of boys' and girls' poultry clubs, H. M. LAMON (*U. S. Dept. Agr., Farmers' Bul. 562, pp. 12, figs. 6*).—In addition to a suggested constitution and by-laws and information concerning the management of poultry, this circular gives a brief outline of 4 years' work for poultry clubs.

Boys' pig clubs, W. F. WARD (*U. S. Dept. Agr., Farmers' Bul. 566, pp. 16, figs. 8*).—This deals with such subjects as the objects of the work of pig clubs, the organization of boys' pig clubs, and general observations on pig management. A sample constitution and by-laws is appended.

The 1913 corn campaign ([*Philippine*] *Bur. Ed. Circ. 80, 1913, pp. 24*).—An account is given of the organization, supervision, finances, and plan of the Filipino boys' corn-growing contest conducted by the Bureau of Education, as a regular part of the industrial work of the public schools of the Philippines.

MISCELLANEOUS.

Annual Report of New Jersey Stations, 1912 (*New Jersey Stas. Rpt. 1912, pp. XXIV+527, pls. 93, figs. 23*).—This contains the organization list of the stations, a financial statement for the State Station for the fiscal year ended October 31, 1912, and for the College Station for the fiscal year ended June 30, 1912, a report by the director, and departmental reports, the experimental features of which are for the most part abstracted elsewhere in this issue. Reports have been previously noted on the inspection of fertilizers (*E. S. R.*, 28, p. 726) and feeding stuffs (*E. S. R.*, 27, p. 774), as well as the text of the laws relating to fertilizers, insecticides, and feeding stuffs (*E. S. R.*, 28, pp. 326, 352, 364).

Third Annual Report of Porto Rico Sugar Producers' Station, 1913 (*Porto Rico Sugar Producers' Sta. Bul. 5 (English Ed.), pp. 68*).—This contains the organization list and reports of the director, pathologist, entomologist, and assistant entomologist, the experimental work recorded being for the most part abstracted elsewhere in this issue.

NOTES.

California University and Station.—The university is cooperating with the Drainage Investigations of this Office in a study of the reclamation of alkali lands by drainage ditches and a pumping system. The 5,400-acre ranch at Kearney Park is to be utilized for this work, of which Walter Wallace Weir has been placed in charge.

The ministers' week, held at Davis December 1-5, 1913, was attended by 485 clergymen.

The class in building construction at Davis is to erect a new farm mechanics building.

Kentucky University and Station.—Ralph Kenney, assistant in farm crops in the college of agriculture, resigned January 1 to accept a position in the Kansas College and Station as assistant agronomist in forage crop work, and was succeeded January 20 by Dillon S. Myer. James E. Mastin, assistant chemist in the food and drugs department of the station, also resigned January 1 to become assistant in chemistry in the Mississippi College.

Massachusetts College and Station.—The extension service of the college has recently established a section of agricultural cooperation and marketing. Assistance is to be given in the organization of cooperative buying and selling associations, rural credit, the finding of a better market for agricultural produce, and other lines of agricultural cooperation. R. H. Ferguson, of Virginia, a graduate of the Ontario Agricultural College and with considerable experience in organizing cooperative associations in New Zealand and the Southern States, has been appointed extension professor in agricultural economics to carry on this work.

The state law relative to the annual report of the station has been so amended as to permit of its publication in installments, the size of edition of each installment up to 20,000 copies being fixed by the director. This change makes possible the publication of the station bulletins as parts of the annual report, and as this report is printed at the expense of the State will increase the station revenues available for other purposes.

A. H. Nehrling, instructor in floriculture in the University of Illinois, has been appointed assistant professor of floriculture in the college. John L. Byard, deputy apiary inspector since 1911, has been appointed superintendent of the apiary.

Minnesota University and Station.—An emergency appropriation of \$15,000 has been granted for hog cholera serum production. This increases the previous appropriations to \$25,000.

The home economics division has been reorganized to take effect August 1, Miss Juniata L. Shepperd and Miss Margaret J. Blair of the college of agriculture being transferred to the extension division as assistant professors of home economics, and Miss Bess M. Rowe of the extension division becoming assistant professor of home economics in the college of agriculture. Robert C. Ashby, of the Washington College and Station, has been temporarily appointed instructor in animal husbandry in the college and assistant in the station in connection with graduate work.

Nevada University and Station.—H. E. Murdock, of this Office, has been transferred from the Kansas Station where he was assistant in irrigation investigations at the Garden City Substation, and will carry on cooperative work with the station and give instruction in agricultural engineering in the university.

New Jersey College and Stations.—Recent resignations include the following: Herman H. Brehme as mosquito inspector, Morris A. Halprin as assistant poultryman, Glenn L. Pyle as assistant chemist, and Henry Jennings as assistant in soil surveying. The following appointments are noted: Willard C. Thompson, assistant in animal husbandry at the Arkansas University and Station, as assistant in poultry work, Arthur C. Ragsdale as assistant instructor in animal husbandry, Chas. H. Richardson, jr., who received the M. S. degree from the Bussey Institution during the past year, as assistant entomologist, W. Andrew Cray as sampler and assistant, and Joseph S. Obecný as field assistant in entomology.

New Mexico College and Station.—The annual farmer's week, given by the college January 19-24, had an enrollment of 116, which was about four times that of the previous year. In addition to the usual agricultural program and domestic science demonstrations, a striking feature was the cooperation of two railroads of the State, these furnishing lectures on the soil moisture problem and successful dry-land farming.

H. H. Simpson, head of the department of animal husbandry in the college and station, has resigned to accept a position as county agriculturist in Colorado.

New York State Station.—Recent appointments include Joseph W. Wellington, formerly of the Indiana Station, as assistant horticulturist, with special attention to truck crops and vegetables, and Clarence D. Parker as assistant chemist.

Ohio State University.—The extension of the present 2-year course over 3 years has been decided upon. Under the new plan the school year will be reduced, beginning October 15 and closing March 15, and thereby, it is believed, making it more convenient for young men actually engaged in farming. An additional year will then be provided to compensate for the shorter period.

A 5-year combination arts-agricultural course became effective January 21 through the cooperation of the college of agriculture with the University of Akron. Under the proposed plan the first 3 years will be spent at the Buchtel College of Liberal Arts of the University of Akron, and the remaining 2 years at the State University. At the end of the fourth year the degree of B. S. is conferred by the former institution and at the end of the fifth year that of B. S. in agriculture by the latter institution. It is announced that other Ohio colleges are considering the adoption of a similar plan.

Oregon College and Station.—A hog raising and dairying demonstration train was operated for two weeks in February in the western and southern parts of the State. The trains contained 7 cars, on one of which were 4 head of dairy cows of improved breeds and 1 animal to illustrate the small and otherwise undesirable Spanish stock. Attention was also given to dairy machinery and creamery equipment and to hog and dairy rations. It is estimated that nearly 40,000 people visited the train and some valuable results are already announced, particularly an increased interest in the building of silos.

The first public school cow demonstration in Oregon was held February 28 in Polk County. There was an attendance of about 200, comprising many teachers of various grades, parents, and children.

The system of industrial clubs is being rapidly extended in the various school districts. Each club may select not to exceed four lines of work from the following list: Corn growing, potato growing, vegetable growing, domestic art, canning, dairy herd record keeping, cooking and baking, poultry raising, pig

feeding, and manual arts. A series of district, county, and state contests is provided, and the prizes consist largely of trips to the college or the state fair, scholarships in short courses, and the like.

Dr. James Withycombe, director of the station for 14 years, has resigned to devote his time to his private interests. During his incumbency of the position, the station staff has increased from 12 to 57 members.

Clemson College and Station.—I. M. Mauldin has been reelected to the board of trustees, W. D. Evans, deceased, has been succeeded by Josiah Evans, and B. H. Rawl of the Dairy Division of this Department by W. D. Garrison, a former superintendent of the coast land substation.

Sidney S. Rittenberg has been appointed to the recently established position of agricultural publicist of the college. Recent appointments in the extension division include J. T. Watt and F. C. Hare as demonstration agents in live stock and poultry respectively.

The semiannual meeting of the county demonstration agents was held at the college February 12 to 14. The principal topic of discussion was the growing of winter cover crops in South Carolina. A farmer's short course was held from January 13 to February 10 with an attendance of 19 farmers.

South Dakota Station.—The station is planning to utilize in breeding experiments six sheep of a comparatively large breed secured by Professor Hansen during his recent explorations in Siberia. These sheep are tailless but have a fat rump, and it is claimed will live for weeks on the fat stored in the body. It is hoped that this feature may be transmitted by crossing with the native sheep, thereby reducing the occasional heavy losses on the range through hunger following severe snow storms.

Federal Commission on Vocational Education.—A joint resolution enacted January 20 authorized the President to appoint a commission of nine to consider the need and report a plan not later than June 1 next for national aid to vocational education. An appropriation of \$25,000 is included for the payment of the expenses of the commission. President Wilson has named as its personnel the following: Senators Smith of Georgia and Page of Vermont; Representatives Hughes of Georgia and Fess of Ohio; C. A. Prosser, secretary of the National Society for the Promotion of Industrial Education; John A. Lapp, legislative reference librarian of Indianapolis; C. H. Winslow of the U. S. Department of Labor; Miss Florence Marshall, principal of the Manhattan Trade School for Girls of New York City; and Miss Agnes Nestor of Chicago, formerly president of the International Glove Makers' Union.

Sixth International Dairy Congress.—This congress will be held at Bern, Switzerland, June 8-10. It will be divided into sections of hygiene, chemistry and bacteriology, the economics of dairying, and general commerce. The first of these sections will consider (1) rules for the veterinary supervision of milk and (2) can systematic selection with a view to improving milk-giving qualities injure the health and resisting powers of cows?

The topics for section 2 will be (1) the seeming uniformity in the methods of chemical analysis of cheese, and (2) the bacteria of milk and their utilization in dairying. Section 3 will consider the rational utilization of the by-products of dairying, and the supply of milk in the great centers of population with reference to economic and social conditions. The marketing of cheese will be considered in section 4, particularly the fixing of standards for the amount of fat in cheese and the means to be adopted to combat dishonest competition in the cheese trade.

A number of excursions will be made to dairies of the vicinity and from May to October the Swiss National Exposition will be held in Bern, in which con-

siderable attention will be given to dairying. Additional information may be obtained from the secretary-general, Dr. R. Burri, Liebefeld, Bern.

American Genetic Association.—Following the change in name of the American Breeders' Association to the American Genetic Association, the *American Breeders Magazine* has been rechristened the *Journal of Heredity*. The association has decided to hold meetings of the three research committees during 1914, but to postpone its next general meeting until 1915, when it will take place at the San Francisco Exposition.

Association of American Agricultural Colleges and Experiment Stations.—At a meeting held February 27, the executive committee of the association decided upon Washington, D. C., November 11–13, as the place and time for the next annual convention.

Agriculture at the British Association.—At the recent meeting of the British Association for the Advancement of Science, the agricultural section held one of its most successful sessions both as to papers and attendance. The presidential address of T. B. Wood, of Cambridge University, has been previously noted (E. S. R., 29, p. 404). Other papers were those on Methods of German Forestry by Frazer Story, The "May-sick" Disease of Cereals and Root Crops by W. E. Collinge, for which he has found sulphur and lime to be successful remedies, The Growing of Flax by Duncan Davidson, The Fungicidal Action of Bordeaux Mixture by B. T. P. Barker and C. T. Gimingham, the Utilization of Sewage in Agriculture by J. Grossman, The Partial Sterilization of Soil by Quick Lime by H. B. Hutchinson, The Protozoa of the Soil by T. Goodey, Nitrification in Pasture Soils by C. T. Gimingham, The Treatment of Peat with Aerobic Soil Bacteria by W. B. Bottomley, The Life History of *Eriophyes ribis* by Miss Adelaide M. Taylor, The Weeds of Arable Land by Dr. Winifred E. Brenchley, Varieties of Corn Spurry by Miss Armitage, and the Possibility of Partnership between Landlord and Tenant by Sir Richard Paget. Joint meetings were also held with the sections of botany and physiology, the former dealing mainly with problems in barley production and the latter with live stock problems.

Agricultural Essay Contest.—Awards have been announced in a contest organized by the Saddle and Sirloin Club of Chicago for the best essay from any graduate or undergraduate from an agricultural college in the United States on the subject Agricultural Education and the Farm. First place and a gold medal valued at \$100 were won by Miss Ethel Vanderwilt, a 1913 graduate of the Kansas College, while second, third, and fourth places, with memberships in the club, went respectively to H. J. Snider, a student in the University of Illinois, Prescott W. Thompson of the University of Missouri, and J. W. Stevenson of Illinois.

Boy and Girl Corn, Potato, and Canning Club Champions.—Over 75 farm boys and girls who, as members of agricultural clubs, have led their States in the production of corn, potatoes, cotton, and tomatoes, and in the home canning of their own garden produce, enjoyed a program from December 11–18, 1913, in Washington. The expense of the trip to Washington was borne by individuals and civic, commercial, and agricultural organizations in the States.

Of the corn club boys Walker D. Dunson of Tallapoosa County, Ala., not only leads the country, but is said to have broken the record for corn production by raising 232.7 bu. on an acre at a cost of only 19.9 cents per bushel. Of the girls the leader in canning and tomato work is Miss Clyde Sullivan of Lowndes County, Ga., who put up 2,464 cans from a yield of 5,354 lbs. of tomatoes on one-tenth of an acre.

New Agricultural School in Southern India.—A new agricultural school was opened in Bangalore, Mysore, in 1913, to turn out "efficient and intelligent

agriculturists." A 2-year course is provided the first year, including practical and theoretical agriculture, elementary and soil physics, elementary chemistry, biology, anatomy, and physiology, and farm mechanics. These subjects are continued during the second year, with additional work in mycology, agricultural engineering, veterinary science, and entomology.

Miscellaneous.—Among the recent appointments for the faculty of the George Peabody College for Teachers are Dr. J. L. Coulter as professor of rural economics, Dr. K. C. Davis, formerly of Rutgers College, as professor of agriculture, and William K. Tate, professor of elementary education at the University of South Carolina, as professor of rural education.

Prof. E. H. Starling has been awarded a medal by the Royal Society for Researches in Physiology. Professor Starling, at the physiological laboratory of the University College, London, has contributed many papers of interest to students of nutrition and of animal physiology, including the results of extended investigations on factors which determine the growth and activity of the mammary glands.

Plans are being prepared for new buildings at the Rothamsted Experiment Station, to be erected in commemoration of the centenary of the birth of Sir John Lawes and Sir Henry Gilbert. Efforts are being made to raise \$30,000 from private contributions, a like amount being then available from the Development Fund.

The Southeastern Agricultural College, Wye, has been given \$2,500 for the extension of its research department. The Development Commission is recommending a grant of \$30,000 for the completion of the college buildings, which are being erected at the Fruit Research Station at Malling, where 22 acres have been purchased by the Kent County Council.

An anonymous donor has pledged to the University of Leeds \$50,000 for the erection of an agricultural building. This will be utilized as the headquarters of agricultural education and research in Yorkshire, but much of the experimental work will be carried on at the Manor Farm, Garforth.

Dr. Chas. Crowther, lecturer in agricultural chemistry, at Leeds University, has been appointed professor and will have charge of experiments in animal nutrition for which a grant has been made by the Development Commission.

W. Lawrence Balls, botanist of the Egyptian Department of Agriculture, has resigned and for the present will devote himself to working up unpublished data on cotton accumulated since 1904.

Under the Swedish budget for 1914, a total of £592,000 is allotted to agriculture. This is an increase of £22,000 mainly for veterinary education and improved roads.

The enrollment in the school of agriculture of Cambridge University has now reached 320. The extension of the buildings has been practically completed.

A bequest of \$25,000 was made by the late Lord Strathcona and Mount Royal for the establishment of a chair of agriculture in the University of Aberdeen.

A separate minister of agriculture has been provided in the Union of South Africa, the first appointee being Hon. H. C. von Heerden.

The biochemical activity of <i>Bacillus lactis erythrogenes</i> , Foster.....	411
The velocity of sugar hydrolysis.—II, The rôle of water, Rosanoff and Potter..	411
The development of fat in the black walnut (<i>Juglans nigra</i>), II, McClenahan..	411
Zygadenin.—The crystalline alkaloid of <i>Zygadenus intermedius</i> , Heyl et al....	412
Zygadenin.—The crystalline alkaloid of <i>Zygadenus intermedius</i> , Loy et al....	412
Some constituents of the leaves of <i>Zygadenus intermedius</i> , III, Heyl and Hepner.	412
Estimation of potassium in potassium silicate, Wilke-Dörfurt.....	412
Microchemical detection of juglone in walnuts (<i>Juglans regia</i>), Tunmann.....	412
Further researches on the testing of oiled paprika, De Sigmund and Vuk.....	413
Characteristic color reaction of soy-bean oil, Settimj.....	413
The detection of shells in cacao and its preparations, Ulrich.....	413
The relative value of indicators in the acid titration of wines, Marre.....	413

	Page.
The determination of phosphoric acid in wine, von der Heide and Schwenk.....	414
Estimation of casein and lactose in milk, Malenfant.....	414
The iodoform reaction of lactic acid, Neuberg.....	414
About the value of the methods for detecting watered milk, Sanfelici.....	414
Interference of hydrogen peroxid with the milk tests for formaldehyde, Gibbs..	414
The extent of the proteolysis in cheese determined by formol titration, Gratz..	415
Starch grains and the use of the counting chamber, Hartwich and Wichmann..	415
About the chlorzinc-iodid reaction of cellulose, Nowopokrowsky.....	415
Acidity in silage: Method of determination, Swanson et al.....	415
Detecting arsenic in fungicidal and insecticidal mixtures, Granderye.....	416

METEOROLOGY—WATER.

Weather and its causes, Barton.....	416
The shifting of climate zones as illustrated in Mexico, Huntington.....	416
Weather conditions, Harcourt.....	416
Monthly Weather Review.....	416
A return to normal atmospheric transparency, Kimball.....	417
The Ohio and Mississippi floods of 1912, Frankenfield.....	417
Rainfall and spring wheat, Blair.....	418
The loss of water due to evaporation, percolation, and absorption, Phillips....	418
Silt in the Rio Grande, Follett.....	418
Chlorin in rain water.....	418
Lead poisoning of a village through the water supply, Neisser.....	418
Introduction to the mycology of water supplies and sewage, Kossowicz.....	418
Germicidal action of ultraviolet light in water, Oker-Blom.....	419

SOILS—FERTILIZERS.

The effect of heat on Hawaiian soils, Kelley and McGeorge.....	419
Rice soils of Hawaii: Their fertilization and management, Kelley.....	420
Introduction to the soils of California, Bailey.....	420
The composition of the soils of south Texas, Fraps.....	420
Soil, Hissink.....	420
Soils, Brunnich.....	421
An interesting soil water question in British Guiana, Bird.....	421
The judgment of soil structure on experimental grounds, Bornemann.....	421
The study of clay, Müntz and Gaudechon.....	422
Estimation of the lime requirement of soils, Bizzell and Lyon.....	422
The circulation of sulphur and chlorin on the earth, Kossovich.....	422
The occurrence of arsenic in soils, Greaves.....	423
Influence of arsenic on biological transformation of nitrogen in soils, Greaves..	423
Factors influencing ammonification and nitrification.—I, Arsenic, Greaves.....	424
Cupric treatments and the nitrification of the soil, Paturel.....	424
Nitrification in acid humus soils, Petit.....	424
Relation between decomposition of cellulose and nitrogen economy, Pringsheim	424
Nitrogen accumulation in continuous rye culture, Ehrenberg.....	424
Nitrogen accumulation in continuous rye culture, Löhnis.....	424
Ammonia evaporation from soil, Lemmermann and Fresenius.....	425
The catalytic power of agricultural soil, Kappen.....	425
The food and habits of life of earthworms in relation to agriculture, Keup.....	425
Soil fatigue, Periturin.....	426
The Illinois system of permanent fertility, Hopkins.....	426
Comparative tests of various fertilizers, Smets and Thomas.....	426
Experiments with fertilizers in West Prussia, Gerlach.....	427
The use of preservatives with liquid manure rich in nitrogen, Meyer.....	427
The industrial synthesis of nitric acid and ammonia, Matignon.....	427
Mustard and buckwheat fertilized with raw phosphates, Gal'tsev and Iakushkin	427
Assimilation of reverted phosphoric acid by plants, Kochetkov.....	428
The German potash salts, Leberke.....	428
Comparative fertilizer tests of common salt and potash salt, Bolin.....	428
Fertilizers, Rose and Heimbürger.....	428
Report of analyses of commercial fertilizers.....	428
Fertilizer analyses, Patten, Marti, Hart, and Jensen.....	428
Analyses of commercial fertilizers, Hartwell et al.....	428
Commercial fertilizers in 1912-13, Fraps.....	428

AGRICULTURAL BOTANY.

	Page.
Applied botany for the colonies, Dubard.....	428
Biology of plants, Neger.....	429
Researches on irritability of plants, Bose.....	429
Chemical and physical changes in geotropic stimulation and response, Schley..	429
Acidity, gaseous interchange, and respiration of cacti, Richards.....	429
Influence of light and of shade on shoots of woody plants, Farenholtz.....	430
Influence of shading on composition of tobacco, Stutzer and Goy.....	430
<i>Asparagus plumosus</i> .—A morpho-physiological study, Newcombe.....	430
The action of atmospheric electricity on plants, Lesage.....	430
Chemical effects of radiant energy in plant processes, Spoehr.....	431
Influence of colloids on microbiological processes, Söhngen.....	431
The behavior of micro-organisms in brines, Peirce.....	431
Alterations in woody tissues and bacterial action in Salton water, Brannon....	431
Effects of soluble humates on nitrogen fixation and plant growth, Bottomley....	431
Inulin metabolism of <i>Cichorium intybus</i> .—II, Grafe and Vouk.....	432
Inulin metabolism of <i>Cichorium intybus</i> , III, Grafe and Vouk.....	432
The physiological significance of anthocyanin in Hedera, Tobler.....	432
Injury to plants by smoke gases and dust, Hasenbäumer.....	432
Injury to vegetation near cyanamid works, Ampola and Vivenza.....	432
Concrecences in forest trees, Zametzer.....	432
The group origin of species, De Vries.....	432
Note on gametic reduplication in <i>Pisum</i> , Pellew.....	433
Factors influencing weight of bean seed.—I, Intra-ovarial correlations, Harris..	433
The cultural bud mutations of tuberous Solanums, Heckel.....	433
On the presence of connecting threads in graft hybrids, Hume.....	433
Anatomy as a means of diagnosis of spontaneous plant hybrids, Holden.....	433
Mistletoe infection in relation to classification, von Tubeuf.....	434

FIELD CROPS.

Agriculture in Abyssinia.—I, Soils and crops, Kostlan.....	434
Experiments with wheat, oats, and barley in South Dakota, Champlin.....	434
[Annual report of the divisions of agronomy and fiber].....	434
Report of government agriculturist and botanist, Mundy.....	434
Report of the agriculturist and botanist, Mundy.....	435
The breeding work at Svalöf, Fruwirth.....	435
Experiments in dry farming.....	435
Dry land pastures.....	435
On the appropriation of nitrogen by legumes, Herke.....	435
The action of sulphur as a fertilizer, Demolon.....	435
Cultivation of cereals with new appliances and by new methods, Kraus.....	435
[Alfalfa production].....	435
A drought-resisting adaptation in seedlings of Hopi maize, Collins.....	436
Influence of distance of planting on fodder corn, Weiser and Zaitschek.....	436
The influence of K-P-N on the growth and production of corn, Vibar.....	436
Experimental hybridization of cotton, Thornton.....	436
Distribution of cotton seed in 1914, Oakley.....	436
Fiber plants, Beauverie.....	436
On the manuring of mangels, Porter.....	437
Spanish peanuts, Wright.....	437
Pine and the Southdown feed industry.....	437
Experiments on the germination of seeds of <i>Poa pratensis</i> , Tomka.....	437
Additional knowledge on the germination of <i>Oryza sativa</i> , Akemine.....	437
Seed selection, Wright.....	437
The cultivation of rice with the help of machines, Main.....	438
Influence of injury and loss of leaves of rye, Schlumberger.....	438
The influence of the previous crop on the yield of rye, von Lents.....	438
Varieties of soy beans found in Bengal, Bihar, and Orissa, Woodhouse and Taylor.	438
Cambodia soy beans.....	438
Soy beans—Why not? Bunn.....	438
Frost-resisting soy beans, Bunn.....	438
Influence of phosphoric acid on development of sugar beets, Wilfarth et al....	438
Sugar-beet culture.....	439
The size of seed ball and germinative ability of beet seeds, Pahn-Appiani....	439
Some figures relative to beet seeds.....	439

	Page.
Sugar-cane experiments in the Leeward Islands, Watts et al.....	439
The study of sugar-cane varieties with a view to classification, Sahasrabudde.....	439
The fuller's teasel, Dallimore.....	440
Production of bright tobacco by the flue and air-curing processes, Taylor.....	440
<i>Trifolium parviflorum</i> and <i>T. angulatum</i> , Szatorisz.....	440
Environmental influences on the characteristics of wheat, LeClerc and Yoder..	440
Breeding work with alternating wheat, Servit.....	441
On the stability of a dwarf variety of wheat, De Vilmorin.....	441
[Wheat production].....	441
Employment of sulphuric acid for destruction of weeds in wheat, Rabaté.....	441

HORTICULTURE.

Biennial report division of horticulture.....	441
[Report of the] division of horticulture, Edwards.....	442
Spraying, Allen.....	442
Florida trucking for beginners, Bateman.....	442
The forcing and blanching of dasheen shoots, Young.....	442
Tomato culture, Anderson.....	442
The present status of the fruit industry of the Dominion of Canada, Macoun..	442
Progress and results in fruit growing in Germany, Lorgus.....	442
Blooming and yields of fruit in relation to minimum temperatures, Ballantyne..	442
A preliminary report on the pollination of the sweet cherry, Gardner.....	443
Commercial peach growing in Michigan, Barden and Eustace.....	443
Systems of planting for orchards, Booth.....	443
Fruit packages in the Middle West, Herron.....	443
Preserving fruits for exhibition purposes, Booth.....	443
The rational manuring of fruit trees and grapevines, Dumont.....	443
The cultivation of the vine under glass, Anderson.....	443
Commercial strawberry culture, Shaw.....	444
Manurial experiments on cacao, 1912-13, De Verteuil.....	444
California citrus culture, Cook.....	444
Date cultivation in the Punjab, Milne.....	444
The palms of British India and Ceylon, indigenous and introduced, Blatter..	444
The selection of the tea plant, Bernard and Van Leersum.....	444
Green manuring, Hope and Tunstall.....	444
Ornamental hibiscus in Hawaii, Wilcox and Holt.....	445
The rational manuring of flowers and ornamental plants, Dumont.....	445
Garden trees and shrubs, Wright.....	445
Shrubs of Florida, Small.....	445
The useful plants of New Caledonia, Heckel.....	445

FORESTRY.

The American woods, illustrated by actual specimens, XIII, Hough.....	445
Specific gravity and weight of the most important American woods, Gaskill...	445
Relation of precipitation to tree growth, Stewart.....	445
Experiments with foreign timber species in Saxony, Neger.....	446
The forest flora of New South Wales, Maiden.....	446
Atlas of the tree species of Java, Koorders and Valetton.....	446
Some Douglas fir plantations.—III, Llandinam, Montgomeryshire, Story.....	446
Lupine straw as a means of improving fir stands on drifting sand, Hesselink...	446
Management of loblolly pine in Delaware, Maryland, and Virginia, Sterrett...	446
Eucalypts, De Noter.....	447
Recent contributions to the knowledge of the genus <i>Hevea</i> , Huber.....	447
The forest problem in Chili, Albert.....	447
Some aspects of European forestry, Recknagel.....	447
Report of the director of forestry of the Philippine Islands, 1913, Ahern.....	447
Report on state forest administration in South Australia, 1912-13, Gill.....	447
The conservation of wood, Barbier.....	447
The transportation of wood in the colonial forests, Jolyet.....	447
Forest fire protection as described at Weeks law conference, edited by Peters..	447
The use of vegetation for reclaiming tidal lands, Case.....	448

DISEASES OF PLANTS.

	Page.
Report of phytopathological observations, 1911 and 1912, Marchal.....	448
Report on plant diseases, Schander et al.....	448
Report on plant protection of the experiment station at Görs, 1912, Bolle....	448
Root nematodes, Vuillet.....	448
Notes on a cereal disease, Pastor.....	448
Appearance and treatment of stinking smut, Appel.....	449
Tests of the hot water treatment of barley and wheat at Pentkowa, Bieler....	449
Antecedents and history of a disease of garlic, Pastor.....	449
On the effect of spraying potatoes with soda Bordeaux mixture, Porter.....	449
Treatment for nematodes, Bruneant.....	449
Selection and treatment of cane seed, Johnston.....	449
Black rot of tobacco, Rapaics.....	450
The mosaic disease of tobacco, Allard.....	450
A new disease of cucumbers, Altheimer.....	450
Tomato rot, Pavarino.....	450
Experiments on the control of the cedar rust of apples, Reed et al.....	450
Evaporation of water by normal or by chlorotic leaves of pear, Crochetelle....	451
On a disease of greengage trees caused by <i>Dermatella pruinastris</i> , Dowson.....	451
Silver-leaf disease, Brooks.....	451
The anthracnose of the mango in Florida, McMurran.....	451
Court-noué, Ravaz.....	451
Court-noué associated with acariose in Swiss vineyards, Faes.....	452
Studies on grape downy mildew, De Istvánffi and Pálinskás.....	452
Studies on grape downy mildew, De Istvánffi and Pálinskás.....	452
Recent researches on grape mildew, De Istvánffi and Pálinskás.....	452
Red scald of grapes, II, Müller-Thurgau.....	452
Some diseases of pecans, Rand.....	452
Observations on rust of mallows, Blaringhem.....	453
Influence exerted on rusts on respiration and chlorophyll assimilation, Nicolas..	453
A twig blight of <i>Quercus prinus</i> and related species, Ingram.....	453
Withertip of fir, Lagerberg.....	453
An undescribed species of Gymnosporangium from Japan, Long.....	453
A leaf disease of Para rubber, Bancroft.....	453

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Guide to the study of animal ecology, Adams.....	454
The birds of Connecticut, Sage and Bishop.....	454
The economic importance of the Hungarian partridge (<i>Perdix perdix</i>).....	454
Examination of contents of stomachs and crops of Australian birds, Cleland....	454
Report of Quebec Society for Protection of Plants from Insects and Diseases..	454
Injurious insects in Brazil, Bondar.....	454
The enemies of the olive, Del Guercio.....	454
The natural enemies of vineyard pests, Feytaud.....	455
Insect enemies of the elm in France, Picard.....	455
Sanitary pathological importance of insects and related arthropods, Göldi....	455
Powdered arsenate of lead as an insecticide, Hinds.....	455
Catalogue of palearctic Hemiptera, Oshanin.....	455
On fungi parasitic on scale insects found in Formosa, Miyabe and Sawada....	455
Development of the eggs of <i>Bombyx (Seericaria) mori</i> the first month, Rizzi....	456
Control of army worm and cotton caterpillar, Worsham.....	456
The wilt disease of gipsy moth caterpillars, Glaser and Chapman.....	456
Notes on a chestnut tree insect, Ruggles.....	456
A list of mosquitoes hitherto reported from New Orleans, Wellman and King...	456
Life history of syrphid fly predaceous on froghopper nymphs, Guppy.....	457
Recommendations for dealing with the froghopper, Kershaw.....	457
A new botfly from reindeer, Knab.....	457
The geographical distribution of the stable fly, <i>Stomoxys calcitrans</i> , Brues.....	457
The domestic fly (<i>Muscina stabulans</i>), Portchinsky.....	457
Narcissus flies, MacDougall.....	458
Notes on the bean fly (<i>Agromyza phaseoli</i>), Jarvis.....	458
Biological studies of the auchmeromyids, Roubaud.....	458
Studies of the auchmeromyids, Roubaud.....	458
Studies of the Diptera with internal entomophagous larvae, II, Pantel.....	458
A catalogue of Coleoptera.....	458

	Page.
The grape flea beetle in France, Picard.....	458
Notes on <i>Podabrus pruinosis</i> , Wilson.....	459
The rhinoceros beetle (<i>Oryctes rhinoceros</i>) in Samoa, Doane.....	459
New potato weevils from Andean South America, Pierce.....	459
Pathogenicity of <i>Nosema apis</i> to insects other than bees, Fantham and Porter ..	459
Evolution and larval forms of <i>Diachasma crawfordi</i> n. sp., Keilin and Picado...	460
The brown-tail and gipsy moths and parasites, Philbrook.....	460
Hereditary infection in <i>Hyalomma aegyptium</i> infected with Crithidia, O'Farrell.	460

FOODS—HUMAN NUTRITION.

The chemical milling and baking value of Utah wheats, Stewart and Hirst....	460
Composition and digestibility of bread and allied foods, LaWall and Graves....	461
Salt in bread making, Freed.....	462
New method of handling preserved foods and its value, Katz.....	462
Report of Missouri Home Makers' Conference Association, 1913.....	462
Household discoveries and Mrs. Curtis's cook book, Morse and Curtis.....	462
Nutrition and diet, Conley.....	463
The history of dietetics, Nichols.....	463
Food and labor, Aiken.....	463
Concerning the food of agricultural laborers, Klöpper.....	463
The enzymic action of fresh foods and condiments, Tadokoro.....	463
Studies on amylases, VI, Sherman and Schlesinger.....	463
Studies on amylases, VII, Sherman and Gettler.....	463
The prolin fraction of the hydrolysis products of casein, Foreman.....	463
The utilization of inulin in diet cures, Goudberg.....	464
The total volume of gastric juice secreted during digestion, Winter.....	464
Influence of melting point of fats on their passage out of stomach, von Fejér...	464
Amino acids, peptones, and proteids, Abderhalden and Lampé.....	464
The thyro-parathyroid in assimilation of carbohydrates, Lombroso and Artom..	464
Significance of pentosans as a source of energy, Schirokich.....	465
Biological significance of phosphorus to the growing organism, I, Masslow.....	465
Concerning phosphates, Maybaum.....	465
Observations during training of a rowing crew, Lehnbecher.....	465
Influence of fatigue on the blood serum, Abderhalden and Lampé.....	466
Influence of cerebrum on metabolism of matter and energy, Hannemann.....	466
Application of second principle of thermodynamics, Báron and Póányi.....	466
Combustion calorimetry and analysis with calorimetric bomb, Diakow.....	466

ANIMAL PRODUCTION.

Feed control officials' convention.....	466
The composition of cotton-seed meal, Fraps.....	466
[Analyses of feeding stuffs].....	466
Feeding stuffs.....	467
Phosphate feeding to animals, Gouin and Andouard.....	467
The growth of animals, Davies.....	467
A review of beef production in the United States, Mumford and Hall.....	467
Steer feeding, Burns et al.....	468
Beef making in southern Texas, Wing.....	468
Value of Oldenburg marsh pasture, Popp.....	468
Color in Shorthorn cattle, Wentworth.....	469
Report of the American Bison Society.....	469
The breeding of caracul sheep, Golf.....	469
Strange sheep of Asiatic Russia, Young.....	469
The sheep and wool industry, Baker.....	469
Spanish goats, Morgan.....	470
Steamed and dried potatoes, von Hertzberg-Hohbüch.....	470
Horse breeding in New Jersey, Minkler.....	470
Distribution of public service stallions in Wisconsin during 1913, Alexander...	470
The commercial fattening of poultry, Lee.....	470
The origin of the "systems of selecting layers," Robinson.....	471
Fifth Annual Conference of Poultry Farmers.....	471
The poultry industry in the United States, Lewis.....	471
A remarkable hybrid.....	471
Ostrich foods and feeding, Dowsley and Gardner.....	472
Ovarian transplantation in guinea pigs, Castle and Phillips.....	472
Color, sex, and fertility: Their relationship in guinea pigs, Prévot.....	472

DAIRY FARMING—DAIRYING.

	Page.
The cost of raising a dairy cow, Bennett and Cooper.....	472
Escutcheon theory in milkers.....	473
On the Normandy breed of cattle, Hédiard.....	473
Russian milch cows, Hansen.....	473
Feeding value of fermented sugar-beet tops for dairy animals, Morgen et al....	473
Beet tops in relation to the microflora and sanitation of milk, Gorini.....	473
Milk hygiene, Marshall.....	473
The improvement of the milk supply in Agra and Oudh, Hailey.....	473
Certified milk, McCleave.....	474
[Reports of state commissioner and chemist], Hanson and Harms.....	474
Daily changes in the specific gravity and fat content of milk, Klose.....	474
Elimination of artificial coloring matter by the udder, Sisley and Porcher.....	474
Influence of fertilizing and feeding on the milk constituents, Allemann.....	475
The influence of work on the milk yield and fat content.....	475
The milk of cows in heat, Steng.....	475
[Reagent for detecting freshness in cows], Scheel.....	475
Changes in milk of cows infected with foot-and-mouth disease, Mezger et al....	475
[Composition of condensed milks], Brunnich.....	475
Process for producing desiccated milk, Dunham.....	476
The function of colloids and their relation to swell, Washburn.....	476
[Butter inspection], Brunnich.....	476
Fat content of cheese, Fincke.....	476
Methods of dividing the proceeds for milk at cheese factories, Zufelt.....	476
Reindeer milk and cheese, Barthel and Bergman.....	476

VETERINARY MEDICINE.

[Veterinary work in foreign countries].....	476
Annual report of the Punjab Veterinary College, 1912-13, Pease et al.....	477
The phosphatids of the kidney, MacLean.....	477
Glycogen of liver of rats bearing malignant growths, Cramer and Lochhead....	477
Biological properties of spleen in experimental nagana, Rondoni and Goretti..	477
About leucocyte-dissolving immune bodies, Leschke.....	477
Immunizing against calves' rennet, Hedin.....	477
The relation of precipitins to complement, Lebailly.....	478
Protecting influence of alexin on protein metabolism, Heilner and Schneider..	478
Influence of sodium chlorid per os on anaphylaxis, Friedberger and Langer....	478
Allowing normal sera to act upon histidin, Friedberger and Langer.....	478
The nature of antianaphylaxis, Weil and Coca.....	478
Precipitation in meat poisoning, Rothacker.....	479
Suprarenal glands and toxi-infections, Marie.....	479
Formaldehyde and salicylic acid on botulinus toxins, Saltet and Zeelandelaar..	479
The experimental production of pernicious anemia in rabbits, Adler.....	479
Diagnosis of anthrax by the Ascoli precipitation method, Oscander.....	480
About the fluctuations of the agglutination titer in glanders, Pavlovich.....	480
Immunizing against glanders, De Blicke and Bubbermann.....	481
The canine piroplasmoses of Europe and Africa, Laveran and Nattan-Larrier..	481
The culture of <i>Babesia (Piroplasma) canis</i> in vitro, Thomson and Fantham....	481
Cultivation of malarial parasites and piroplasms in vitro, Ziemann.....	481
On the multiplication of <i>Piroplasma canis</i> in vitro, Knuth and Richters.....	481
Formation of acute anaphylaxis from acid-fast bacteria and neutral fat, Leschke.	481
Notes on the biology of the tubercle bacillus, Smith.....	481
Do bovine tubercle bacilli occur in sputum of human subjects? Würmlin....	482
Growth and virulence of the causative organisms of fowl tuberculosis, Carl....	482
The tuberculin tests for tuberculosis in cattle, Hallman.....	482
The vaccination of cattle against tuberculosis, Calmette and Guérin.....	482
The hog cholera question, Pekar.....	484
What the experiment station hog serum laboratory is doing, Haring.....	484
About pyobacillosis in pigs and serum treatment for the same, Stenström.....	484
Epizootic encephalomyelitis in the horse, Quevedo.....	485
Some aspects of mange in horses, Pillers.....	485
A new means of transmitting the fowl nematode, <i>Heterakis perspicillum</i> , Scott..	485

RURAL ENGINEERING.

	Page.
Selection and installation of a small pumping plant for irrigation, Etcheverry.	485
About irrigation of cultivated soils, Krüger.....	486
Irrigation of the Ica Valley, Sutton.....	486
Irrigation by lateral percolation, Ringelmann.....	486
Irrigation and water power laws of Nebraska in force July 17, 1913.....	486
Irrigation laws [of New Mexico].....	486
Irrigation laws of Wyoming in effect September 1, 1913.....	486
[Subsoil drainage for preventing malaria], Strickland.....	486
Economies of highway location; formulas and methods employed.....	486
Action of calcium chlorid on roads, Newman.....	486
Earthwork haul and overhaul, Fish.....	487
Tests with mortars and concrete mixed with asphaltic oils, Taylor and Sanborn.	487
Concrete on farms, Wilson.....	487
[Information regarding concrete farm structures].....	487
A treatise on the inspection of concrete construction, Cochran.....	487
Farm gas engines, Hirschfeld and Ulbricht.....	487
Drive belts, their use and care, Krohne.....	488
Application of electric drive in greenhouses.....	488
The mechanical preparation of cereals for seed, Wacker.....	488
Centrifugal cream separators, Tödt.....	488
Farm ice houses, Pickett.....	489
The silo—how to make it permanent.....	489
A combined silo and water tank.....	489
The pneumatic water system, Beattie.....	489
A mechanically cleaned Berkefeld filter, Grimm.....	489
Design of Imhoff sewage plants, Frank and Fries.....	489
Regulating the climate of the house, Riley.....	490
Agricultural drafting, Howe.....	490

RURAL ECONOMICS.

Rural economics.....	490
The organization of American agriculture, Houston.....	490
Marketing of farm produce under present market systems, Virtue.....	490
Farm-management survey in Indiana, Illinois, and Iowa, Thomson and Dixon.	490
Possible agricultural development in Alaska, Chubbuck.....	491
Farm tenancy in Iowa, Hibbard.....	491
York state rural problems, I, Bailey.....	491
Rural life in Canada, MacDougall.....	491

EXPERIMENT STATION RECORD.

VOL. XXX.

APRIL, 1914.

No. 5.

The change which has taken place in the volume of agricultural writings since the journal entitled *Agricultural Science* ceased publication in 1894 is strikingly illustrated by the present overcrowded condition of the many scientific journals which bear upon that field. At that time a single journal standing for agricultural science in the United States experienced difficulty in securing the necessary material and support to warrant continuance at the end of an eight-year experiment. Now the reports of agricultural investigations are scattered widely through scientific journals, with numerous organs for special branches, and workers in certain lines even find it necessary to look abroad for a suitable avenue of publication.

The volume of investigation of direct interest to agriculture has immensely increased, even in the last decade. This is largely because the work of the agricultural experiment stations, the National Department of Agriculture, and similar institutions has been greatly strengthened, yielding a large amount of material which is thought better suited to scientific journals than to bulletins and reports. But aside from this, the interest of a wide range of workers and teachers in the scientific aspects of agriculture has been wonderfully quickened, and the field has appealed increasingly to men not directly identified with the subject. There is now both a producing and a reading public of large size—an acceptance of economic papers on agricultural subjects in many avenues where they were formerly not favored.

The chief difficulty at present in securing publication for such papers in the leading scientific journals is the space limitation, and this is becoming serious. Practically all the journals are overloaded with material, with the result that publication is slow, a year or more sometimes elapsing after a paper is accepted. This is manifestly unsatisfactory, for promptness in publication is highly desirable, and interest is often diminished if the delay is long continued. It is discouraging to those who have important new work to report. The establishment of new journals seems to relieve the situation only temporarily. There must be a practical limit to the number of these, and the remedy for the present congestion must be largely looked for elsewhere than in indefinite extension of agencies.

There are two possible avenues of relief—a more critical examination and sifting of the papers submitted as to their merit, and the requirement of greater condensation in the papers accepted for publication. There is undoubted opportunity along both of these lines. Greater discrimination would not only relieve the congestion but would often result in benefit to the journals and to the majority of readers, and have the effect of establishing higher standards.

No one can follow the current periodicals of natural science without noting a great diversity in the manner of reporting scientific work, and a frequent lack of proportion between space and importance. A prolixity is conspicuous that often robs articles of much of their interest, a lack of concentration in style and upon the subject in hand.

The language of science as there expressed is often far from being the clear, direct, concise thing we naturally expect it to be, considering the nature of science itself. Order is its first rule, the establishment of systems of relationship. This would suggest that scientific papers, in comparison with other writings, should be characterized by an orderly, logical marshaling of facts, freed from extraneous and confusing details, and a critical weighing of the evidence in the light of theory and of what had gone before. If this were carried out it is feared that many of our scientific papers would be so simplified and condensed their authors would hardly recognize them and would perhaps feel that they had lost much of their technical character.

Too frequently the language of the scientific journal is quite the opposite. It is, to speak quite plainly, verbose, confused by more or less trivial details, and unnecessarily involved as a result of much discussion and speculation and the recital of objection to the work of others. It is as if the author recognized nothing else on the subject as available to the reader, and were attempting not only to record all of his data and their relation to previous studies, but the mental stages by which he arrived at his interpretations, and to meet in advance possible criticism of his procedure, his results, and his reasoning. Some papers are so diffuse and discursive that both a summary and a series of conclusions are deemed necessary by the authors to make their claims clear. Details are recorded which can only be of interest to the exceptional reader, and there is little evidence of the attempt to segregate matter of permanent importance from the trivial and incidental.

This is a severe stricture. It does not of course apply to all articles by any means, but to a considerable extent the practices referred to appear to mark a tendency in present journal literature. The writing habit has become thoroughly established, and with it the feeling that the published paper must form a complete record of work. There is much padding, doubtless unconsciously in many cases, but

the result is a prodigal abuse of the facilities for publication. Relatively small pieces of work are combined with theoretical discussions based mainly on the literature and analogies and speculation, resulting in disproportionately long papers of doubtful value for publication as a whole. These historical, theoretical, or controversial discussions are often quite academic, not strictly germane to the work reported, and better suited to a seminar or a scientific meeting than to a journal of progress.

Again there is an apparent confusion of the preliminary announcement with the paper which records the completed work up to a certain point. What is in effect only a preliminary announcement is expanded into a journal article by blocking out the field, reviewing previous work, and outlining the author's plans and activities, with some preliminary results. Such articles are often interesting, but they are hardly entitled to displace more mature articles in journals already overcrowded.

The most productive investigators are not by any means the most prolix or voluminous writers, and the influence which a worker is exerting in his branch of science is not necessarily measured by the space he occupies in the scientific press. A thorough and conclusive piece of research needs little argument to support its contentions and few labels to secure recognition of originality.

There seems to be among some workers, if not a wrong point of view an impractical one in regard to the publication of their scientific work, a conception of the essentials of a scientific paper which is disadvantageous to the writer and the reader alike.

Accounts of investigations are written first of all for the average scientific reader, or the majority of specialists who will be likely to be interested in them, rather than for the exceptional person. If they have not considerable breadth of interest their acceptance by a journal may be a matter of doubtful expediency. They are written to be read, to present in an effective way the product of investigation. The public has a right, as a rule, to expect that each paper will represent a discovery or a definite contribution, either of permanent fact or theory. It is not to be a mere record for the gratification of the writer; it is written for the reader, and hence it should show consideration of him—his needs, his time, his convenience. If it fails in this—if it is written entirely from the writer's own viewpoint and his desire to file a complete and detailed record which he can refer to, it will lose much of its interest and effectiveness, and may be a doubtful tax on publication facilities.

Journals of science are rarely privately supported or endowed but usually depend mainly on public contribution, either as membership or subscription fees. It is their mission, therefore, to print what is

presumably of interest to their particular public, assuming a general familiarity with the field represented. This implies a necessary limitation upon a journal, which the contributors of articles are expected to observe, and an obligation on the part of the editors if a publication of distinctive and high grade character is to be maintained.

It is to be assumed that the reader of technical papers know something of the subjects treated—that he is enough of a specialist to understand the bearings of the contributions. His primary interest in any particular case is in learning just what definite contribution the author has made, and how he has attained his end. He needs to have a sufficient general survey of the literature to make it clear where the author took up the subject. But this does not mean a complete review of all previous studies, dating back to the inception of the subject; and to give page after page of citation and summary lengthens the paper quite unnecessarily. Most scientific articles are not designed as monographs, and they are not written for the wholly uninitiated or to serve as text-books, but primarily to record new progress.

The first step is to secure an orderly and effective presentation, one which will enable the reader to get readily a connected and intelligent idea of the findings. This implies an orderly sequence in the mind of the writer, with ability to put himself constantly in the position of the reader. It requires painstaking work. Evidence of haste and lack of consideration in the presentation of scientific work is far more conspicuous than it should be. Years are spent in attaining results and only hours in presentation. Men often seem impatient of effort spent in trying to secure a clear, concise form of statement of their studies, and once their paper is written have a strong aversion to change; but it is upon this care and clearness that a just conception of the work and permanent recognition will largely rest.

It is said of the late Dr. S. W. Johnson that his writings represented the very best he was capable of. As his biographer says: "He was constitutionally incapable of turning off work hastily. Not only must his knowledge of the point involved be exhaustive and accurate, but each paragraph even if of minor importance was rewritten many times before it was parted with; when finally sent off it was as clear as it could well be made, representing the best he could do with the subject." In this day of much writing such an example is well worthy of imitation.

A printed paper is a permanent product. It can not be revised and rearranged and amplified like a lecture, but it must stand as it is issued. It is printed presumably because it contains something

worth while recording permanently. It represents a finished product as far as it goes. Hence it is well worth care and consideration.

The selection of material to be included is a vital matter, and one which many writers find most difficult. It is very rarely practicable, and nearly as rarely desirable, to include all the data secured in an investigation. There are always gradations in value; a great deal of that pertaining to intermediate steps is unessential in detail to the majority of readers and does not justify the expense of publication. Even in the more important aspects of the work all the figures and observations and determinations can rarely be published. Summaries must naturally be depended upon, with sufficient explanation to make clear the scope of the work done, the range of variation found, and the justification for the figures and deductions as given.

Not a few persons contend for the publication of practically all of their data—an essential transcript of their notebooks. Considering the present congestion of scientific journals such a contention is not a reasonable one. Rarely, indeed, are the data so intrinsically important as to warrant publication in full, and insistence on it deprives someone else of the privilege of publication and his prospective audience of the opportunity of reading. Many authors seem to have difficulty in judging what is the most important in their own articles. Undue emphasis is laid on trivial points or side issues. The results of large numbers of observations on a particular point are recorded merely to show the reader that they were made and that there is practical uniformity, whereas a statement of the extent of the observations, the nature of the range, and the general result would answer every reasonable purpose.

Again, detailed individual records are made of negative results, which in themselves have no permanent value not expressed in a brief text statement. Results are platted, although they confessedly show no definite relationship and permit of nothing more than negative inferences. The value of a negative result is not disputed, but when it merely indicates the author was not on the right track it rarely justifies detailing. Other data are recorded for their own sake, in the evident hope that someone will be able to make more out of them than the author apparently has, for he ventures no comment or deduction.

The desire of writers to make their published articles a complete record of their studies is often founded in the criticism of some readers, who seem to assume that if everything is not given something important is being withheld, a captious attitude which is difficult to combat successfully. Manifestly the reading public must take the author's word for it that he has made the number of observations

he claims and been honest in his presentation of results. The contention that the reader should be able to check up completely the author's findings from the published account is not believed to be generally justified. Few indeed would attempt such a proof of the work or search for flaws in details, and for those few the full original data can be much more cheaply preserved in notebooks and files, accessible when necessary.

However we may feel about the extent to which it is desirable to report scientific data, and it is admittedly a nice question, not determined by any set rules, the real question is what is feasible as far as the agencies for publication are concerned, and what is essential as far as the reader and the permanent value of the paper are concerned. The reader has a right to the scientific evidence, but evidently there must be a limit, suggested by the exigencies of the situation and dependent upon the intrinsic value of the details and incidental matter. The practical question is as to what is essential and may reasonably be expected; and it is believed to be quite clear that in many instances the practical bounds are at present overstepped.

These matters have a direct bearing on the standards of our scientific journals. Some of them are not all that could be desired, either from the standpoint of the science or the men who contribute to them. They are lax in their requirements and restrictions as to the character of the papers and their form, and remiss in the examination of manuscripts. It means little to have articles accepted by such journals, because the papers submitted are not subjected to discriminating scrutiny and selection made on actual merit. This robs these agencies of the stimulus and the influence which they might properly exert.

The effect is especially unfortunate in the case of the young worker in science, for it lowers his standards and gives him a wrong point of view. He is naturally ambitious to appear in print. The acceptance of immature or low-grade work tends to make him self-satisfied, and stands in the way of developing higher ideals. This is particularly desirable in agricultural science. The workers in that field need all the help they can get in raising their work to high grade.

Considerable of the scientific literature of to-day reflects a wrong idea of the nature of science and of what scientific writings should be. It is inexact, loose in statement, and based on superficial or inconclusive work. It does not bear evidence of the critical weighing of fact and expression which is expected in a scientific paper, and it mixes new findings with common knowledge in a manner to cause confusion. It shows a lack of discrimination on the part of the managers of such journals which is inexcusable at the present time and with the present supply of material.

More than thirty years ago Dr. Johnson wrote to a correspondent who had proposed the establishment of a journal: "In our stage of agricultural experimentation there is need of a moderately large amount of judicious criticism." This need has not passed. The absence of it is one of the conspicuous deficiencies in the present situation. There has been no established agency or forum for it, and those who have been most competent have seemed to shrink from indulging in it. A critical attitude toward method and results has been little in evidence.

It is easy to run along in grooves, doing things as they have been done, assuming that because they have been done that way for a long time they are correct and incapable of further improvement. It is easy to overlook the fact that work which is in the realm of research at one period becomes commonplace and lacking in originality or progress in another. It is perhaps natural to accept the findings of one time and build upon them, when in reality the problems have so changed that they need quite different treatment. But a certain measure of reflection and critical study is quite as necessary, and quite as productive in the end, as any other form of activity. It is an essential of progress, and it is an element in originality.

The scientific journal, through its board of editors, can exercise a useful function as a discriminating critic, especially if it will take pains to explain its real objections and indicate the weaknesses of papers it rejects. It can do much by way of suggestion, and if consistent in its attitude it can bring about a modified point of view as to the essentials of a scientific article.

The scientific societies offer another opportunity for constructive criticism. Papers and discussions of this nature would often be quite as profitable as a program made up entirely of reports of investigation and would represent advanced thought. One agricultural society has with profit given considerable attention to the critique of certain classes of methods. This might well be extended to other features which are vital to right experimenting and right thinking. The scientific meeting is an appropriate place for such discussion. Such a gathering gives opportunity for plain speaking, with less danger of offense because less likely to be misunderstood.

In the older sciences broad criticism is recognized as desirable and essential to progress, and is indulged in freely. The feeling is that if methods and theories and deductions will not stand the test of critical analysis the sooner this is known the better. The same view should prevail in relation to agricultural science. We need more sound, sympathetic, constructive criticism.

Such criticism should deal with conditions and tendencies as they are, and be made from a broad-minded point of view, not with the

object of tearing down, but in the manifest effort to improve and strengthen. It should, of course, be impersonal, and free from anything in the nature of an attack. It will avoid controversy. It will deal with principles rather than with individuals, and its effort will be to lead by the force of reason rather than harsh judgment. The manner in which it is done may have much to do in relieving it of odium and making it effective.

The task is a delicate one, and not to be lightly undertaken if good is to be effected. But it is an important and essential function, and one of great opportunity for usefulness and influence which will be farreaching. It is work for the very best talent. Encouragement and commendation have been the order of the past; to these should be added discrimination, a looking behind and beyond the returns in the endeavor by critical analysis to get at real values, just bases of estimate, and avenues for possible improvement.

RECENT WORK IN AGRICULTURAL SCIENCE.

AGRICULTURAL CHEMISTRY—AGROTECHNY.

General chemistry of the enzymes, H. EULER, trans. by T. H. POPE (*New York and London, 1912, pp. IX+323, figs. 7*).—This is a translation of the revised and enlarged German edition of this work, which has been previously noted (E. S. R., 24, p. 608).

In regard to the action and regeneration of proteolytic enzymes, N. N. IWANOFF (*Trudy Imp. S. Peterb. Obshch. Estestvo. (Trav. Soc. Imp. Nat. St. Petersb.)*, 43 (1912), I, No. 2-3, pp. 95-106, 128).—It has been shown in previous work (E. S. R., 27, p. 108) that KH_2PO_4 increases the capacity of the proteolytic ferments in befanol. Leucin and tyrosin have no influence on this process. An extract of befanol was found to contain a proteolytic enzym. The action of KH_2PO_4 manifests itself by the production of an excess of peptone during the autolytic process. Adding KH_2PO_4 to a watery extract of befanol which had been previously heated to from 75 to 80° C. or to gentle boiling produces a regeneration of the enzym peptase.

Studies on enzym action.—IV, Note on the occurrence of a urease in castor beans, K. G. FALK (*Jour. Amer. Chem. Soc.*, 35 (1913), No. 3, pp. 292-294).—The work, which continues that previously noted (E. S. R., 29, p. 713), indicates that castor beans contain a urease which is inactivated by heat in an aqueous solution or suspension.

Studies on enzym action.—V, The action of neutral salts on the activity of castor bean lipase, K. G. FALK (*Jour. Amer. Chem. Soc.*, 35 (1913), No. 5, pp. 601-616).—In this work, which is a continuation of that noted above, "the actions of neutral salts of the uni-univalent types, [the chlorids, iodids, fluorids, nitrates of sodium and potassium, potassium bromid, lithium chlorid, lithium nitrate, and sodium acetate], and the uni-bi- and bi-bivalent types, [the chlorids and nitrates of barium, calcium, and magnesium, sodium sulphate, potassium sulphate, sodium oxalate, manganous chlorid, manganous sulphate, and magnesium sulphate], were tested on the activity of a castor bean lipase preparation toward ethyl butyrate under comparable conditions. In every case the change in activity, whether increase or decrease, was found to be a continuous function of the concentration of the salt added. Decreased activities, as compared with aqueous solutions, were shown by all the uni-univalent salts, by the chlorids and nitrates of barium and calcium (except for the most dilute solutions) and magnesium, by sodium oxalate, and by dilute solutions of sodium sulphate.

"Increased activities were shown by dilute solutions of the chlorids of barium and calcium, by more concentrated solutions of sodium sulphate, by magnesium sulphate, and by the chlorid and sulphate of manganese. Potassium sulphate solutions gave the same results as purely aqueous solutions. . . . If an explanation of the retarding actions of the various salts be looked for, it may perhaps be found in the coagulation of the enzym (either alone or together with other substances) by the addition of the salts, the ions of which produce their

individual specific effects in each case. The unionized molecules may also take part in these reactions. The accelerations can not be explained in as simple a manner except, perhaps, for the cases where increased formation of active lipase (as by manganous salts) may be assumed."

Action of enzymes on hexose phosphate, V. J. HARDING (*Proc. Roy. Soc. [London], Ser. B, 85 (1912), No. B 581, pp. 418-422; abs. in Jour. Chem. Soc. [London], 102 (1912), No. 601, I, p. 928*).—The lipase from the castor bean and emulsin from almonds hydrolyze hexose phosphate slowly, and no hydrolysis at all is produced by the pancreas of the bovine. Zymine in an aqueous solution hydrolyzes hexose sulphate slowly. An autolyzed yeast juice was found strongly hydrolytic, and the enzyme producing it can be precipitated from the juice with alcohol and ether.

Nephelometry in the study of proteases and nucleases, I, P. A. KOBER (*Jour. Biol. Chem., 13 (1913), No. 4, pp. 485-498, figs. 2*).—This describes a microchemical method in which the nephelometer is employed for following the digestion of a soluble protein, edestin. The instrument, which is described in detail, can be made from a Duboscq colorimeter.

"The readings of the nephelometer plotted against the ratios of the solutions, for a given standard solution and a given height of standard, seem to follow a uniform curve which can be expressed in the equation $y = \frac{s}{x} - \frac{s(l-x)k}{x^2}$ where y = height of 'unknown' solution, s = height of standard solution, x = ratio of solutions. The studies of various precipitants for protein and other organic substances in dilute solutions are in progress with the view of extending the application of this method generally. The ease, the rapidity, and the accuracy of the method would make it very useful, if the proper precipitants can be found. By proper dilution it can be used for large amounts of substances, and is sensitive enough to determine 0.00002 gm. with a percentage error of less than 2 per cent. The determination of casein in milk and the estimation of minute quantities of ricin are receiving immediate attention."

Nephelometry in the study of proteases, II, P. A. KOBER (*Jour. Amer. Chem. Soc., 35 (1913), No. 3, pp. 290-292*).—"The nephelometer can be used for studying the digestion of casein when a 3 per cent solution of sulphosalicylic acid is used as a precipitant. This reagent does not precipitate amino acids, peptids, peptones, and urinary constituents under the conditions given for nephelometry. The nephelometric constant for casein with this precipitant was found to be 0.2."

On the purification of phosphatids, H. MACLEAN (*Bio-chem. Jour., 6 (1912), No. 4, pp. 355-361*).—"The alcohol-soluble phosphatid of kidney and muscle is lecithin with a N:P ratio of 1:1. Though substances containing different amounts of nitrogen are obtained in the different extracts, the application of the method described—emulsification and precipitation with acetone—gives a single product of the nature of an ordinary lecithin. No alcohol-soluble substance having a higher percentage of nitrogen than that of lecithin has been found.

"From an aqueous extract of the nitrogenous impurity of lecithin a substance of basic nature crystallizes out; after the separation of this substance the mother liquor is very effective in curing polyneuritis (beri-beri). This explains the anomalous results of many observers who have endeavored to cure pigeons suffering from beri-beri by lecithin."

Tannic acid fermentation, I, L. KNUDSON (*Jour. Biol. Chem., 14 (1913), No. 3, pp. 159-184, figs. 2*).—The results show that "tannic acid is toxic to a large number of fungi at relatively low concentrations. *Aspergillus niger* is a

more vigorous fermentative organism than *Penicillium* sp. The fermentation was found to be more rapid in the gall nut infusion than in the synthetic solution in which tannic acid was the only source of carbon. The presence of other organic compounds in the gall nut infusion protected to a certain extent the gallic acid. The addition of 5 per cent sugar did not protect the gallic acid, but simply increased the growth. The addition of 10 per cent sugar protected the gallic acid entirely. When gallic acid and cane sugar to the extent of 5.5 per cent and 10 per cent, respectively, were offered together, the cane sugar was elected and the gallic acid left in the culture solution. Fermentation can take place under anaerobic conditions, and 1 mg. of mycelium is sufficient to effect the transformation of 2.706 gm. of tannic acid in 10 days. In an approximately 15 per cent solution of tannic acid, fermentation was most rapid when the tannic acid alone served as the source of carbon, and when aerobic conditions were maintained; yet the method of fermentation is wasteful from the standpoint of an economical yield of gallic acid."

See also a previous note (E. S. R., 26, p. 203).

Tannic acid fermentation.—II, Effect of nutrition on the production of the enzym tannase, L. KNUDSON (*Jour. Biol. Chem.*, 14 (1913), No. 3, pp. 185-202).—Previously noted from another source (E. S. R., 27, p. 408).

A preliminary study of the biochemical activity of *Bacillus lactis erythrogenes*, M. LOUISE FOSTER (*Jour. Amer. Chem. Soc.*, 35 (1913), No. 5, pp. 597-600).—In addition to the work previously reported (E. S. R., 26, p. 775), it is shown "that the action of *B. lactis erythrogenes* on milk is progressively catabolic; the native proteins are split with the ultimate formation of monoamino and diamino acids. This proteolytic change may be caused by an enzym. A soluble ferment which was precipitated with alcohol split the carbohydrate with the production of formic and acetic acids. This would seem to indicate the presence of an intracellular enzym which has been set free by the alcohol when it has destroyed the organism. Accompanying these changes is the production of a pigment which causes a coloration varying from red to dull brown, according to the strain. This pigment can be extracted with amyl alcohol and is extracellular, for it is contingent upon the life of the organism."

A reinvestigation of the velocity of sugar hydrolysis.—II, The rôle of water, M. A. ROSANOFF and H. M. POTTER (*Jour. Amer. Chem. Soc.*, 35 (1913), No. 3, pp. 248-258).—In a former communication* it was shown that sugar hydrolysis is strictly unimolecular with respect to the sugar itself. In the present contribution it is stated that "water plays a double rôle in the reaction. On the one hand it takes part in the reaction and contributes to its velocity according to the law of mass action; on the other hand it acts as a negative catalyzer by its dissociating power. With respect to this retarding effect, the reaction is shown to follow a catalysis principle which is also obeyed by several other reactions investigated within the past few years."

The development of fat in the black walnut (*Juglans nigra*), II, F. M. McCLENAHAN (*Jour. Amer. Chem. Soc.*, 35 (1913), No. 4, pp. 485-493, fig. 1).—This is a continuation of the investigations previously noted (E. S. R., 21, p. 628) and includes a preliminary study of the relation of potassium and phosphorus to the fat and lipoids as they occur in developing the seed coat and ovule of the walnut. The curve of the development of the fats in the ovule of the black walnut is only complementary to the water-soluble portion of the hot alcohol-ether extract.

"The earliest history of the ovule would indicate a great preponderance of phosphatids over fats, which may be noted by an inspection of the backward

* *Jour. Amer. Chem. Soc.*, 33 (1911), No. 12, pp. 1911-1924, fig. 1.

extension of the phosphatid curve and that of fats in the ovule. The phosphatids linger in the developing ovule until August 14, but their relative importance is insignificant after the fruit has changed from a limpid liquid to a jelly. This is the case with the seed coat also, except that their importance seems to be nil after the June 28 sample. It will be seen that the early life of the ovule is conditioned by the presence of a relatively large content of potassium, which becomes less and less important as the fruit advances toward maturity, but even on September 4 there is a content equal to 0.18 per cent of the total solids.

"The nature of the tissue of the seed coat is such that it is either not penetrable by tannin or contains substances that disrupt the tannin molecule into fragments that under one form or another are able to penetrate the tissue. The line of limitation of tannin penetration in the seed coat is so clearly marked, and yet the premises for a definite conclusion are so fragmentary, that this feature of the physiology of the plant life deserves a special study before one should speak finally in reference to the rôle that fats and tannins play with reference to one another."

Zygadenin.—The crystalline alkaloid of *Zygadenus intermedius*, F. W. HEYL, F. E. HEPNER, and S. K. LOY (*Jour. Amer. Chem. Soc.*, 35 (1913), No. 3, pp. 258–262, figs. 2).—This has been adequately noted from another source (*E. S. R.*, 28, p. 506).

Zygadenin.—The crystalline alkaloid of *Zygadenus intermedius*, S. K. LOY, F. W. HEYL, and F. E. HEPNER (*Wyoming Sta. Bul.* 101, pp. 91–98, figs. 2).—A reprint of the above article.

Some constituents of the leaves of *Zygadenus intermedius*, III, F. W. HEYL and F. E. HEPNER (*Jour. Amer. Chem. Soc.*, 35 (1913), No. 6, pp. 803–811; *abs. in Science*, n. ser., 37 (1913), No. 957, pp. 678, 679).—Since poisonous properties have been ascribed to the resin *Z. venenosus* by Tyrode, the investigation was extended to the search for toxic resins in *Z. intermedius*. No toxic substance was isolated, although an extensive investigation was made with the plant with the methods elaborated in the Wellcome Research Laboratories of London. Some physiological tests were also made with the resin upon dogs by Mendel of Yale University, which showed that the resin was nontoxic.

From an ether solution of the tartaric acid fraction of the resin a yellow crystalline substance was obtained, which melted at 317 to 318° C. with decomposition and corresponded in its properties to quercetin. An alkaloid was noted in extracts from the tartaric acid solution in this investigation, but the product obtained could not be made to crystallize. Physiologically it did not show any marked toxic properties when 0.1 gm. was given subcutaneously to guinea pigs.

Other substances isolated were dextrose, phytosterol, a hydrocarbon hentriacontane, oleic and linoleic acid, and isolinoleic acid. In the ether extract of the resin a neutral substance was found but to which no formula could be assigned. In this fraction a polyhydric alcohol similar to ipuranol was noted.

Analyses of the ash constituents present in the plant are given. For previous work see above.

Estimation of potassium in potassium silicate, E. WILKE-DÖRFURT (*Ztschr. Analyt. Chem.*, 51 (1912), No. 12, pp. 755–760; *abs. in Jour. Chem. Soc. [London]*, 102 (1912), No. 602, II, p. 1211).—"For the estimation of potassium in commercial potassium silicate ('phonolith') the original Lawrence Smith method (ignition with calcium carbonate and ammonium chlorid, boiling the mass with water, etc.) is recommended. Verwey's modification of this process, which dispenses with the removal of the calcium before proceeding to the separation with platinum, gives results largely in excess of the truth."

Micro-chemical detection of juglone in walnuts (*Juglans regia*), O. TUNMANN (*Pharm. Zentralhalle*, 53 (1912), No. 36, pp. 1005–1010, figs. 5; *abs. in*

Jour. Chem. Soc. [London], 102 (1912), No. 601, II, p. 1110).—If the green shell of an unripe walnut is immersed in a copper acetate solution, crystalline needles of the copper-juglone compound begin to form immediately in the cells, while the hydrojuglone, which exudes from the cells, forms a precipitate. "If the section is now washed with water and treated with chloral hydrate solution the masses of crystals which at first appeared black become red. On subjecting a section of the tissue to the action of nitric acid vapors, black crystals (juglonic acid?) form in the cells. A further test consists in treating a section on a microscope slide with a drop of anilin and placing a cover glass over it; after the lapse of a few minutes, reddish-brown crystals form in the anilin near the edges of the cover glass. The sections may be also subjected to micro-sublimation and the sublimate tested with the above mentioned reagents."

The crystals give a red coloration with sulphuric acid, reddish with dilute potassium hydroxid, a violet coagulum forming at the edge of the drop, and violet-blue with ammonia gas.

Further researches on the testing of oiled paprika. A. DE SIGMOND and M. VUK (*Kísérlet. Közlem., 15 (1912), No. 2, pp. 289-292*).—Continuing the work previously noted (*E. S. R., 27, p. 715*), the authors have tried a method for detecting added oil in paprika which consists in leaching the surface oil with water and determining the ether extract in the resulting solution. The method gave unsatisfactory results when it was used for both pure and oiled goods. The iodine numbers of the oils and natural and oiled goods were unreliable.

Some other experiments showed that various solvents extract different quantities of substances from the pericarp of the paprika fruit, e. g., ethyl ether 5 per cent, ethyl alcohol 18.9 per cent, and methyl alcohol 34.3 per cent. The latter results were obtained by macerating 3 gm. of paprika with 100 cc. of the solvent for 48 hours at room temperature of from 20 to 22° C.

Characteristic color reaction of soy-bean oil, L. SETTIMI (*Abs. in Jour. Chem. Soc. [London], 102 (1912), No. 601, II, p. 1108*).—The reaction is as follows:

To 5 cc. of oil in 2 cc. of chloroform add 3 cc. of a 2 per cent aqueous solution of uranium nitrate, and shake. If the sample is soy-bean oil, a lemon-yellow-colored emulsion is produced. Some samples of olive oil gave a faint yellow emulsion, but all other oils tried showed white. Soy-bean oil gave the remaining usual reactions for seed oils while olive oil did not.

The detection of shells in cacao and its preparations, C. ULRICH (*Der Nachweis von Schalen im Kakao und in seinen Präparaten. Diss., Herzogl. Tech. Hochsch. Carolo Wilhelmina, Braunschweig, 1911, pp. 97*).—In addition to what has been previously reported (*E. S. R., 29, p. 205*), it is shown that Filsinger's and Drawe's elutriation methods can be used for detecting additions of cacao shells from 7.5 per cent up in normal cocoa which contains 30 per cent of fat and water, providing the sample under examination is finely powdered and the appropriate correction factors are applied in the calculations.

The Matthes and Müller modification of König's method for crude fiber is not deemed of value for practical conditions, as it will not detect less than 27.5 per cent of shell in normal cocoa. The pentosan detection according to the Tollens and Kröber method is also imperfect as it will note only 25 per cent or upwards of shells. The iodine value of the cacao fat gives no clue so far as adulteration is concerned.

Numerous analyses of raw and prepared materials are included.

The relative value of indicators in the acid titration of wines, F. MARRE (*Rev. Gén. Chim., 15 (1912), No. 13, pp. 242, 243; abs. in Jour. Chem. Soc. [London], 102 (1912), No. 601, II, p. 1106*).—As an indicator in the analysis of

colored wines, a mixture is recommended of "a cold saturated solution of phenolphthalein in alcohol (7 gm. in 90 cc. of alcohol) and fluorescein (1.2 gm.) dissolved in 100 cc. of cold alcohol. To 5 cc. of clear (or filtered) wine, 5 drops of the phenolphthalein and 3 drops of the fluorescein solution are added, the mixture is just heated to boiling, diluted with 5 cc. of water, and subsequently titrated."

The determination of phosphoric acid in wine, C. VON DER HEIDE and J. SCHWENK (*Ztschr. Analyt. Chem.*, 51 (1912), No. 10-11, pp. 615-627).—The authors state that in wine phosphoric acid occurs as a primary phosphate and as organic phosphoric acid. The latter is only a small part of the total acid. With the Philippe and Duperthuis method both kinds can be separated, but if the phosphoric acid is precipitated by the von Lorenz method only the inorganic form is obtained. The Grete method yields the total amount of phosphorus. The total amount of phosphoric acid can also be determined in the ash of the wine, and the ashing may be done either by the wet or dry method. For table and sweet wines, musts, or yeast, no addition of soda or nitric acid for the purpose of preventing losses during ashing is necessary.

The preferable method for determining phosphoric acid in wine is given as follows: Fifty cc. of the wine is evaporated and carbonized in the usual manner. Wines containing a large amount of sugar are allowed to ferment previous to determining the phosphoric acid. The carbon is then extracted with water, ashed, dissolved in nitric acid, the original water extract of the ash added, and filtered. The ash can be burned in an electric oven to whiteness in one operation. The phosphoric acid is determined in the resulting solution.

The German official method is deemed unsatisfactory.

Estimation of casein and lactose in milk, R. MALENFANT (*Jour. Pharm. et Chim.*, 7. ser., 6 (1912), No. 9, pp. 390-397; *abs. in Jour. Chem. Soc. [London]*, 102 (1912), No. 602, II, p. 1218).—"Ten cc. of the milk is added to a mixture consisting of 25 cc. of 65 per cent alcohol and 3 drops of glacial acetic acid, and after shaking for about 30 seconds, the precipitated casein is collected on a weighed filter and washed with 65 per cent alcohol. The filtrate and washings are collected in a 100 cc. flask, diluted with water to the mark, and the lactose is estimated in a portion of this solution by titration with Fehling's solution. The casein is then washed with boiling 95 per cent alcohol, boiling acetone, and ether, dried for 7 hours at 100° C., and weighed. The weight found is multiplied by 0.925 to obtain the quantity of casein present."

The iodoform reaction of lactic acid, C. NEUBERG (*Biochem. Ztschr.*, 43 (1912), No. 5-6, pp. 500-507; *abs. in Jour. Chem. Soc. [London]*, 102 (1912), No. 601, II, p. 1106).—The author finds that the α -lactic acid gives the iodoform reaction, and that the other substances giving it are pyruvic acid, aldol, β -hydroxybutyric acid, quercitol, and inositol. The statements in the text-books are consequently deemed incorrect.

About the value of the methods for detecting watered milk, R. SANFELICI (*Staz. Sper. Agr. Ital.*, 45 (1912), No. 5-6, pp. 321-375).—This is a detailed and critical review of the methods proposed for the detection of watered milk. Numerous samples of milk were examined as regards specific gravity at 15° C., the fat-free solids, and the specific gravity of the serum. The specific gravity of the serum is considered of great value for added water detecting.

Interference of hydrogen peroxid with the milk tests for formaldehyde, H. D. GIBBS (*Philippine Jour. Sci., Sect. A*, 7 (1912), No. 2, pp. 77, 78; *abs. in Jour. Chem. Soc. [London]*, 102 (1912), No. 602, II, p. 1218).—"The Hehner and Leach tests for the presence of formaldehyde in milk are unsatisfactory in the presence of hydrogen peroxid, although the Rimini reaction may still be

employed. After removal of hydrogen peroxid by means of reducing agents, positive tests may, however, be obtained."

The extent of the proteolysis in cheese determined by formol titration. O. GRATZ (*Kisérlet. Közlem.*, 15 (1912), No. 2, pp. 281-288).—The formol (formaldehyde) titration method (E. S. R., 19, p. 808) as a means for determining the extent of proteolysis measured by the amount of carboxyl groups is deemed satisfactory for studying the proteolytic changes taking place in cheese. The results obtained by this investigation compare well with the figures given for monoamino acids by precipitation with phosphotungstic acid.

A few observations on starch grains and the use of the counting chamber as an aid for the quantitative determination of adulteration in vegetable powders. C. HARTWICH and A. WICHMANN (*Arch. Pharm.*, 250 (1912), pp. 452-471).—This deals with the use of the counting chamber for determining stone cells and clove stems in clove powders, sandal wood in saffron powder, and the variety of starches in a mixture.

About the chlorzinc-iodid reaction of cellulose. I. V. NOWOPOKROWSKY (*Izv. Imp. St. Peterb. Bot. Sada (Bul. Jard. Imp. Bot. St. Petersb.)*, 11 (1911), No. 4-5, pp. 109-116).—As this reaction, while reliable, is very capricious, a study was made to determine the best procedure for applying it, and consequently of the behavior upon cellulose and its products of the individual constituents which make up the reagent.

In most of the chlorzinc-iodid solutions the amount of potassium iodid is so large that the coloration obtained is not typical, and at times it is violet or red instead of blue. If small amounts of potassium iodid and iodine are taken, the color becomes typical, but the intensity of the color suffers.

It is stated that the most satisfactory results can be obtained by the use of separated solutions. The preparation is treated for a few seconds with 1 drop of a 1 per cent iodine and 1 per cent potassium iodid solution and then with a strong zinc chlorid solution (2 parts of zinc chlorid to 1 part of water). The preparation is dropped into the zinc chlorid solution, and it must be colored intensely blue in from 1 to 1½ minutes. If it is not colored properly, a little potassium iodid is added.

The method is given preference over those of Schultze, Behrens, or von Höhnelt.

Acidity in silage: Method of determination. C. O. SWANSON, J. W. CALVIN, and E. HUNGERFORD (*Jour. Amer. Chem. Soc.*, 35 (1913), No. 4, pp. 476-483).—Investigators, as a rule, determine the acidity in silage by extracting the acid with either water or alcohol and titrating with a standard alkali solution, using phenolphthalein as an indicator. Esten and Mason (E. S. R., 27, p. 204), Hart and Willaman (E. S. R., 28, p. 109), and Dox and Neidig (E. S. R., 29, p. 712) used water as the solvent, although with certain kinds of silage it yields an extract which is difficult to filter. Alcohol as a solvent has not been thoroughly studied by experiment station chemists.

This work was done on several kinds of silage, and on different samples of the same silage. In all cases, however, the ratio between the silage and the solvent was 1:10. In order to make the results comparative, they were calculated to acetic acid. The presence of carbon dioxide in silage had little effect upon the acidity figures, although it is believed advisable to use recently boiled water for the extraction. Fineness of grinding was found to have considerable influence upon the ultimate results.

Upon comparing the acidity in the water and alcohol extracts, it was noted that alcohol was the more efficient solvent, but 50 per cent alcohol was nearly

as effective as 95 per cent. The weaker alcohol extracted 0.06 to 0.09 per cent less acid than the stronger, but gave an extract which was easier to filter and titrate, which may account for the difference in the titration figures. "Since equally uniform results are possible with either the water or the alcohol extraction, and since the alcohol extracts contain a high percentage of acidity in every case, it must follow that some of the acids in silage which are soluble in alcohol are insoluble in water. The amounts of these insoluble in water are different in the various kinds of silage, corn silage having the largest relative amount."

The conditions of extraction—shaking by hand or machine—were also studied.

A method of detecting arsenical compounds in fungicidal and insecticidal mixtures, L. M. GRANDERYE (*Vie Agr. et Rurale*, 2 (1912), No. 27, p. 34; *abs. in Internat. Inst. Agr. [Rome], Bul. Bur. Agr. Intel. and Plant Diseases*, 3 (1912), No. 7, p. 1679).—In order to determine quickly whether an insecticide or fungicide contains arsenic, the following simple process is recommended:

"Four spoonfuls of good white vinegar are put into a tumbler, and some crystals of soda are added gradually until the resulting effervescence ceases. The liquid is then poured into an iron ladle which is heated till nearly all the water has evaporated; when this point is reached, a few grams of the compound suspected of containing arsenic are mixed with the contents of the ladle and heated still more, until the mass is desiccated. If arsenic is present, a gas is set free with a strong repulsive odor of garlic."

METEOROLOGY—WATER.

Weather and its causes, E. C. BARTON (*Queensland Geogr. Jour., n. ser.*, 26-27 (1910-1912), No. 12-13, pp. 16-37, fig. 1).—General weather phenomena are explained, and the use of kites and balloons in upper air exploration is discussed.

The shifting of climatic zones as illustrated in Mexico, E. HUNTINGTON (*Bul. Amer. Geogr. Soc.*, 45 (1913), Nos. 1, pp. 1-12, figs. 3; 2, pp. 107-116).—Observations are reported upon which is based a theory that there have been shiftings of climatic zones of more or less intensity at varying intervals of time. "In the irregular little cycles which cause the climate, or weather, of one year to differ from that of the next, the course of the storm tracks varies, moist periods in subtropical regions being characterized by southerly tracks. In longer periods . . . the same sort of variation is seen on a larger scale. Therefore it seems reasonable to suppose that in still longer and more important periods the same thing occurs with a correspondingly increased intensity."

The theory "assumes that a given change of climate will produce opposite effects on the northern border of the subtropical zone of aridity as compared with the southern border. If this is so, it might be expected that the fluctuations of the lakes around Mexico City would indicate conditions exactly the reverse of those recorded in the growth of the sequoias in California. This, however, is only partially the case."

Weather conditions, G. HARCOURT (*Ann. Rpt. Dept. Agr. Alberta*, 1912, pp. 37-48).—Monthly and annual maximum and minimum temperatures and sunshine for 1912 and precipitation for 1899 to 1912 at a number of places in Alberta are given in tables.

Monthly Weather Review (*Mo. Weather Rev.*, 41 (1913), Nos. 9, pp. 1285-1464, pls. 13; 10, pp. 1465-1637, pls. 9, figs. 12).—In addition to the usual climatological summaries, lake levels, weather forecasts and warnings for

September and October, 1913, river and flood observations, lists of additions to the Weather Bureau library and of recent papers on meteorology, a condensed climatological summary, climatological tables and charts, and notes on the rivers of the Sacramento and Lower San Joaquin watersheds during the months of September and October, 1913, by N. R. Taylor, and on streams and weather of the Upper San Joaquin watershed, by W. E. Bonnett; these numbers contain the following special papers:

No. 9.—Relation of precipitation to tree growth, by M. N. Stewart (see p. 445); Thunderstorm at Charleston, S. C., September 9, 1913, by J. H. Scott; The Storm of September 3, 1913, in Eastern North Carolina, by L. A. Denson; The September Hot Wave in Los Angeles, Cal., by F. A. Carpenter; and Notes on the Severe Heat and Drought Over the Middle West During the Summer of 1913 (illus.), by P. C. Day et al.

No. 10.—Heavy Rainstorms of 1913 at New York City, by C. D. Reed; Tornadoes in Wisconsin on October 10, 1913, by W. R. Bormann; Rainfall and Spring Wheat (illus.), by T. A. Blair (see p. 418); The Tornado of October 9, 1913, in Nebraska, by G. A. Loveland; The Tornado of October 9, 1913, at Lebanon, Kans., by E. V. Bower; Heavy Rains and Resultant Floods in Southwestern Louisiana September 26 to October 4, 1913, by I. M. Cline; Storms in Southeastern Louisiana October 23, 1913, by I. M. Cline; and A Meteorological Study of Parks and Timbered Areas in the Western Yellow-Pine Forests of Arizona and New Mexico (illus.), by G. A. Pearson.

A return to normal atmospheric transparency, H. H. KIMBALL (*Jour. Wash. Acad. Sci.*, 4 (1914), No. 2, pp. 17-25, fig. 1).—This paper presents evidence derived from observations at Mount Weather, Va., relative to the gradual precipitation from the air of dust from the Katmai Volcano, June 6 and 7, 1912.

Summarizing the results, it is stated that "pyrheliometric and polarimetric observations unite in indicating a gradual increase in atmospheric transparency since the marked minimum in August, 1912. This increase is probably due to the precipitation from the atmosphere of the dust that was introduced into high levels by the eruption of Katmai Volcano in June, 1912.

"At the same time, the solar and the antisolar distances of the neutral points of Babinet and Arago, respectively, indicate that there may still be traces of this dust in the upper atmosphere.

"The duration of the Katmai dust cloud appears to have been less than the duration (2 years) of the dust cloud that followed the eruptions of 1902-03, and markedly less than the duration (3 years) of the dust cloud that followed the eruption of Krakotoa in 1883."

For notes on the effect of these dust clouds upon temperature and evaporation at the earth's surface, see previous articles (E. S. R., 29, p. 720).

The Ohio and Mississippi floods of 1912, H. C. FRANKENFIELD (*U. S. Dept. Agr., Weather Bur. Bul. Y*, pp. 25, pls. 42).—This bulletin notes the extent of the Mississippi drainage basin, the causes and frequency of Mississippi River floods, and reports the origin, progress, duration and crest stages of the Mississippi and Ohio floods of 1912. Comparative data of crest stages show that new high water marks were established from Cairo to New Orleans, except in the vicinity of Vicksburg where a higher stage was prevented by crevasses.

Data from the 1912 flood and floods in 1903, 1897, and 1882 show a steady increase in flood height below Cairo without a corresponding increase in quantity of precipitation, which is attributed to the influence of levees. Since the duration of the 1912 flood was also greatest, it is concluded to be relatively the most important.

A number of weather maps, precipitation charts, and hydraulic and hydrographic diagrams accompany the report.

Rainfall and spring wheat, T. A. BLAIR (*Mo. Weather Rev.*, 41 (1913), No. 10, pp. 1515-1517, figs. 3).—The rainfall and yield of wheat in the three great spring wheat producing States of Minnesota, North Dakota, and South Dakota are compared in tables and charts. It is shown that the total precipitation of May and June is, in most years, probably the largest factor in determining the wheat yield in the two Dakotas but not in Minnesota.

On the loss of water due to evaporation, percolation, and absorption, with special reference to the Brisbane water supply, G. PHILLIPS (*Queensland Geogr. Jour.*, n. ser., 26-27 (1912), No. 12-13, pp. 1-15, fig. 1).—The author briefly reviews data from several sources which indicate the enormous losses of water through evaporation, percolation, and absorption by soil and vegetation in various localities, particularly Queensland. He concludes that the evidence given is sufficient to show "how difficult it is to determine with anything like exactitude the quantity of water that any given area may be depended upon to yield, or that can be conveyed by natural or artificial channels other than closed conduits such as pipes.

Silt in the Rio Grande, W. W. FOLLETT (*U. S. Dept. State*, pp. 102, pl. 1; *abs. in Engin. News*, 71 (1914), No. 1, pp. 18-21).—This is a compilation and discussion by the author, as consulting engineer of the International Boundary Commission and advisory engineer of the Commission for the Equitable Distribution of the Waters of the Rio Grande, of silt determinations of Rio Grande waters made prior to January 1, 1913. Methods of procedure are described.

The data show that the silt is a factor which must be seriously considered in the building of any reservoir on the Rio Grande. The most prominent fact brought out is that no hard and fast rule can be made as to what silt the river will carry in future years. During the 16 years' observation the actual percentage of silt in the river water varied from 0.76 to 4.14, with an average of 1.66 per cent.

Chlorin in rain water (*Agr. Students' Gaz.*, n. ser., 16 (1913), No. 5, p. 174).—During the year ended September 30, 1913, the rainfall at Cirencester was 33.02 in., containing chlorids equal to 40.78 lbs. per acre of common salt.

Lead-poisoning of a village through the water supply, M. NEISSER (*Gesundhs. Ingen.*, 36 (1913), No. 51, pp. 920-922).—Attention is drawn to a case in which an entire small rural community was stricken with lead-poisoning through the water supply. Service pipes, house connections, and some of the plumbing were of lead. Tests of the spigot water showed a considerable lead content, which increased with the length of the lead house connection. The water from the supply contained considerable oxygen and free carbon dioxide. The lead in the water appeared to be either in colloidal or insoluble form, as all evidences of it were removed by filtering through a Berkefeld filter. The author also briefly reviews other studies of lead poisoning, and concludes that if water has a carbonate hardness of 7 degrees or more it will hardly attack lead pipe, but if the hardness is only 3 degrees or less and considerable oxygen, free carbon dioxide, and some nitrates are present, one may expect comparatively strong lead solutions.

Introduction to the mycology of water supplies and sewage, A. Kossowicz (*Einführung in die Mykologie der Gebrauchs- und Abwässer*. Berlin, 1913, pp. VII+222, figs. 62).—This work is meant to serve two purposes: (1) As a guide for chemists, botanists, and technologists, in beginning the study of hydrobiology and the purification of water supplies and sewage, and (2) as a reference book for bacteriologists, hygienists, and hydrobiologists. For the first pur-

pose several different processes of water and sewage purification are described and illustrated, and the fundamental principles of their operation emphasized. For the second purpose an exhaustive review of technical literature on the subject is given, bringing out the most salient features developed.

The germicidal action of ultraviolet light in clear, turbid, and colored water, M. OKER-BLOM (*Ztschr. Hyg. u. Infektionskrank.*, 74 (1913), No. 2, pp. 197-247).—Investigations are reported on the practicability of water sterilization by ultraviolet light, in which the retarding action on the germicidal action of the ultraviolet light of turbidity and coloring in the water within natural limits was particularly tested. *Bacillus coli communis*, *B. paratyphosis B*, *Vibrio el-tor*, and *B. peptonificans* served as test bacteria.

In tests of a commercial drinking water sterilizer, with the water perfectly clear and colorless, sterility with regard to the test bacteria was obtained when the water passed through the apparatus at a speed of from 50 to 90 liters (13.2 to 23.8 gals.) per hour, and had a bacterial content of about 10,000 per cubic centimeter. The exact limits for the germicidal effect of the apparatus relative to speed and bacterial content of the water were not established. No great difference was observed in the resistance of the different test bacteria to the germicidal action of the ultraviolet rays, but the water bacteria were more resistant than the test bacteria. Clay turbidity reduced the germicidal effect of the ultraviolet rays, but with a low turbidity the retarding action was small.

Large quantities of peat extract coloring also reduced the germicidal action, but weak mixtures had little retarding effect. Medium quantities of humus substances in the treated water did not especially hinder germicidal action. Barium sulphate turbidity and vesuvin coloring had little retarding effect. A bibliography is appended.

SOILS—FERTILIZERS.

The effect of heat on Hawaiian soils, W. P. KELLEY and W. McGEORGE (*Hawaii Sta. Bul.* 30, pp. 38).—In the investigations reported in this bulletin 12 different soils, representing a wide range of types and agricultural conditions, were heated to 100 and 250° C. and to ignition, and the effect of these treatments on the solubility in water and fifth-normal nitric acid of the mineral constituents and on the form and loss of the soil nitrogen was studied.

The results were variable, but in many cases there was an increase in the solubility of the inorganic soil constituents as a result of heating. An important exception was a decrease in solubility of lime and magnesia at the higher temperatures and of iron at the lower temperatures.

The solubility of the constituents of soils used in aquatic agriculture was found to be abnormally high, but when these were dried this was not so pronounced, and when such soils were heated after drying they were affected much the same as dry-land soils.

The conclusion is reached that no single factor is sufficient to explain fully the solubility effects resulting from heating. It is thought, however, that this is due mainly to physical causes, more particularly to the action of the heat in evaporating the water films surrounding soil particles which hold the soluble matter under high pressure, thus leaving the soluble constituents deposited on the surface of the particles in condition to be more readily taken up when water is again added. It is also recognized that heating may benefit soils by improving aeration.

Heating to 200° C. or above caused a loss of approximately 25 per cent of the total nitrogen of the soil, practically destroyed all nitrates, and stopped nitrification, but it resulted in an abnormally large production of ammonia,

mainly from the monamino acid group. This increase in the production of ammonia and the checking of nitrification were also observed in field soil on which brush had been burned.

Rice soils of Hawaii: Their fertilization and management, W. P. KELLEY (*Hawaii Sta. Bul. 31, pp. 23*).—Studies of the origin, composition, fertilizer requirements, and management of these rice soils are reported.

It is shown that the Hawaiian rice soils are of basaltic origin, but also contain small amounts of coral limestone. They are generally clay loams containing approximately equal quantities of fine sand, silt, fine silt, and clay. In chemical composition the soils are quite uniform except those from the Waikiki district, which contain abnormal amounts of magnesia, and those from the Kaulaunui district, which are highly organic. In general, the nitrogen and phosphoric acid are high, while the potash is low, due to leaching from the soil.

Fertilizer experiments carried on through seven crops showed that the application of 150 lbs. per acre of ammonium sulphate produced notable increases in the yield, but 300 lbs. per acre proved the more profitable. Potash and phosphoric acid were without effect. Application of ammonium sulphate to both the spring and fall crops was considerably more profitable than application to the spring crop only. The residual effects on the fall crop from the spring application were small. The immediate effects from application to the fall crop were about the same as those obtained with the spring crop.

A complete fertilizer proved no more effective than ammonium sulphate alone, whereas a mixture of ammonium sulphate and potassium sulphate was less effective than ammonium sulphate alone. Nitrate of soda alone gave poor growth. Moreover, the nitrate was reduced in the submerged soils to nitrites, which are poisonous to rice. Very little nitrification took place in the submerged soils; ammonification, however, went on, not so vigorously as in aerated soils, but sufficiently to supply the nitrogen needs of the rice, provided sufficient organic matter was present.

Conditions favoring aeration are not considered desirable because nitrification sets in immediately after such conditions are produced and the nitrates thus formed become converted into poisonous nitrites upon resubmergence, or are lost through leaching. A rotation of crops, including the plowing under of a legume, is recommended, but when no rotation is practiced it is better to leave the land unplowed until just before planting the next crop.

Introduction to the soils of California, G. E. BAILEY (*Los Angeles, Cal., 1913, pp. 171, fig. 1*).—This book gives an elementary discussion of agricultural geology, soil forming materials, land forms, processes of soil formation, soil classification and its importance, soil particles, soil moisture, organic matter in soils, subsoils, soil movement, and soil permanency and a description of the soils of California as to their location, origin, and agricultural value, dividing them into clay, adobe, silty clay, silt loams, loams, sandy adobe, fine sandy loams, fine sand, hardpan, and alkali soils.

The composition of the soils of south Texas, G. S. FRAPS (*Texas Sta. Bul. 161, pp. 65*).—This bulletin, the third of a series (*E. S. R., 23, p. 315*), contains a description of the soil types of about 33 counties in the southern portion of Texas, notes on their present agricultural uses and productiveness, and also chemical analyses of a number of samples of these types, together with an interpretation of the results.

Soil, D. J. HISSINK (In *Dr. K. W. Van Gorkom's Oost-Indische Cultures. Amsterdam, 1913, vol. 1, pp. 33-116, figs. 11*).—This work deals with soil formation and composition, physical and chemical properties of soil, and soil biology,

and describes certain of the cultivated soils of Java and Deli and of Sumatra, more especially those of Deli.

The Java sugar cane soils in general contain between 0.5 and 63 per cent of sand and coarse matter and from zero to 45 per cent of fine silt. They are divided into clay, sandy, and gravel soils. The majority of these soils are said to contain more than 0.5 per cent of assimilable lime, although the heavier soils are richer in assimilable lime than the lighter. The total potash content lies between 0.37 and 1.53 per cent, and the phosphoric acid content between 0.01 and 0.27 per cent. It is claimed that sugar soils containing only 0.006 per cent of phosphoric acid yielded a good crop when irrigated with silt-laden water. The productiveness of sugar soils is said to depend largely on the content of nitrogen and organic matter, the soils containing from 0.03 to 0.16 per cent of nitrogen and from 0.7 to 3.5 per cent of organic matter. The organic matter contained from 2 to 7 per cent of nitrogen.

The Java tea soils are of volcanic origin, corresponding to laterite and containing considerable hygroscopic water. For productiveness a high humus content is considered necessary. These soils contained from 2.9 per cent organic matter and 0.12 per cent nitrogen for old worn-out tea soils to 8.1 per cent organic matter and 0.39 per cent nitrogen for very productive tea soils. The organic matter is said to contain about 5 per cent nitrogen. The acid-soluble phosphoric acid content lies between 0.09 and 0.22 per cent, the potassium between 0.03 and 0.10 per cent, and the lime between 0.02 and 0.12 per cent.

The coffee soils contain considerable humus which contains about 5 per cent nitrogen. Although the humus is not acid the soils are said to need lime.

The tobacco soils are largely weathered laterite, containing much coarse material and little plant food, the light sandy soils containing more phosphoric acid, however, than the heavier soils. The Deli tobacco soils are, in the order of their humus content and productivity, black sandy humus, sandy clay chocolate colored, red brown, and red soils. The characteristics of the best tobacco soils are said to be a high content of humus, nitrogen, phosphoric acid, soluble potassium, and soluble basic colloidal aluminum silicates, containing much hygroscopic water, and of such a composition that a hard clay mass is not formed.

Soils, J. C. BRUNNICH (*Ann. Rpt. Dept. Agr. and Stock [Queensland], 1912-13, pp. 53, 54, 58-71*).—Analyses of soil samples which are said to be well distributed over the State of Queensland show the majority of them to be acid. The results of soil moisture determinations indicate "the importance of thorough cultivation for the conservation of moisture in the soil."

Analyses of rocks and limestones indicate that "limestone of high quality exists in the State."

An interesting soil water question in British Guiana, M. BIRD (*Jour. Indus. and Engin. Chem., 5 (1913), No. 12, pp. 1012, 1013*).—Analyses of soils from sugar estates on the coastal lands of British Guiana which are reported show that these soils are well supplied with plant food but contain a decided excess of magnesia over lime. The drainage waters from these soils show, in some cases, as much as 480 parts of alkali per million of water, and also a large excess of magnesia over lime. There is a large loss of sugar in the case of cane grown on these soils due to the fact that the excess of magnesia in the juice interferes with the crystalization of the sugar. The difficulty was corrected by the liberal application of lime to the soil.

The judgment of soil structure on experimental grounds, BORNEMANN (*Mitt. Deut. Landw. Gesell., 28 (1913), No. 45, pp. 620-623*).—A soil sampling cylinder with a special cutting edge is described, which it is claimed will elimi-

nate the errors in determining the structure and density of a soil which are due to loss of part of the sample, disturbance of the structure, adhesion to the sampler, and errors in determining the depth of sample.

As a means of preparing sections of soils for the study of their structure, the samples were immersed in a melted 3:1 mixture of paraffin and stearin, which was then allowed to harden and thus preserve the original structure intact. Studies of sections of a plowed and scarified moist loam by this method showed the scarified soil to be in much the better physical condition for plant growth.

The study of clay, A. MÜNTZ and H. GAUDECHON (*Compt. Rend. Acad. Sci. [Paris]*, 157 (1913), No. 21, pp. 968-974, fig. 1; *abs. in Rev. Sci. [Paris]*, 51 (1913), II, No. 23, pp. 731, 732; *Jour. Chem. Soc. [London]*, 106 (1914), No. 615, I, pp. 127, 128).—For determining the fineness of clay the authors studied the division of the clay particles in a given time at different heights in a homogeneous suspension. For producing sedimentation they employed gravity and the combined action of gravity and an electrical field. By the use of gravity the larger particles settled more rapidly while by the use of the electrical field the finer particles settled more rapidly.

It is considered possible by these methods to establish a purely artificial classification of clays, indicating for each the quantities deposited from the suspension during an arbitrarily chosen period of time.

Estimation of the lime requirement of soils, J. A. BIZZELL and T. L. LYON (*Jour. Indus. and Engin. Chem.*, 5 (1913), No. 12, pp. 1011, 1012).—A modification of the barium hydroxid and ammonium chlorid method proposed by Albert is described, and tests of the method in comparison with that of Veitch are reported. The proposed method is thought to be more rapid and as accurate as that of Veitch.

On the circulation of sulphur and of chlorin on the earth, and on the importance of this process in the evolution of soils and in the plant world, P. S. KOSSOVICH (*Zhur. Opytn. Agron. (Russ. Jour. Expt. Landw.)*, 14 (1913), No. 3, pp. 181-228; *abs. in Internat. Inst. Agr. [Rome]*, Mo. Bul. Agr. Intel. and Plant Diseases, 4 (1913), No. 10, pp. 1522-1526).—The following topics are discussed: Chlorin and sulphur in rocks and soils, atmospheric precipitation, and subsoil waters; the rôle of chlorin and sulphur from atmospheric precipitation in soil evolution; and chlorin and sulphur contents and requirements of plants.

Rocks were found to contain only small quantities of chlorin and sulphur, and soils only small amounts of slightly soluble sulphur which decreased with the depth. Soils rich in humus contained as high as 0.1 per cent of sulphur.

Data collected in European Russia and available data for other countries indicate that the chlorin and sulphur contents of the several atmospheric precipitations vary widely, the chlorin from 0.4 to 71.9 parts per million and the sulphur from 0.28 to 90.2 parts per million, while the yearly averages vary within much narrower limits. The quantities of these elements falling with the precipitation per acre per year varied considerably in the localities examined, the chlorin in most territories being between 8.92 and 22.30 lbs. per acre, and the sulphur between 8.92 lbs. in the country and 72 lbs. per acre in the neighborhood of towns and industrial works, where the greatest portion falls in winter. The chlorin content of the atmospheric precipitation increased as the locality approached the seas and oceans or bordered on salt lands, and slight precipitations generally contained more chlorin than the heavier ones.

Theoretical considerations led to the conclusion that soil and subsoil water contains more chlorin and sulphur than atmospheric precipitation due to the evaporation of the latter, and that the relative chlorin and sulphur contents

of soil and subsoil water vary in the same wide limits as the ratio between atmospheric water that penetrates into the soil and that which evaporates. The content of these elements in the subsoil water is said to vary with the locality, from season to season and from year to year.

The continuous introduction of sulphur from the atmosphere is considered a necessary condition for vegetation and soil evolution, on account of the rapid impoverishment of the soil in sulphur by weathering and leaching. In soils and subsoils in which no underground water is formed the accumulation of sulphur and chlorin compounds due to atmospheric precipitation will, in a brief period, from a geological view-point render a soil too saline for most cultivated crops. On the other hand, the formation of a relatively insignificant quantity of subsoil water is sufficient to prevent an accumulation of these compounds.

Compiled analyses are reported to show that the cultivated crops are relatively rich in sulphur, which, expressed as SO_4 and referred to air-dry matter, ranges in the grain of cereals from 0.29 to 0.45 per cent, and in straw 0.26 to 0.55 per cent, while clover hay contains 0.41, lucern hay 0.50, peas 0.45, beans 0.58, soy beans 0.85, turnips 1.85, and cabbage 2.05 per cent.

It is concluded that in certain cases an impoverishment of the soil as to sulphur is possible, and, consequently, that sometimes for a succession of heavy crops the application of fertilizers containing sulphur becomes necessary. Apparently, the circulation of chlorin consists chiefly in a mechanical transport between the land, the seas, and the atmosphere, while the circulation of sulphur is much more complicated; on the one hand, passing continuously from inorganic to organic form and vice versa, and on the other hand, undergoing oxidation and reduction, largely by bacterial activity.

The occurrence of arsenic in soils, J. E. GREAVES (*Biochem. Bul.*, 2 (1913), No. 8, pp. 519–523).—From a study of the arsenic content of many western orchard soils the author concludes that “some virgin soils contain arsenic in appreciable quantities which comes from the decay of the native rocks. Many cultivated orchard soils contain it in large proportions, but there is no uniform relationship between the total quantity of arsenic in different soils and the water-soluble arsenic of these soils. A soil containing over 100 parts per million of total arsenic contained much less water-soluble arsenic than did a soil carrying only 5 parts per million of total arsenic. The solubility of the arsenic found in a soil is governed largely by the salts in the soil and the form in which the arsenic is applied.

“Different portions of the same soil, to which equivalent quantities of various so-called insoluble arsenical compounds had been added, showed great dissimilarities in water-soluble arsenic content. The portion to which Paris green was added contained four times as much water-soluble arsenic as did a portion of the same soil to which an equivalent quantity of lead arsenate had been applied. Arsenic trisulphid, when first applied to soil, is less soluble than lead arsenate, but as time progresses, at least in some soils, the arsenic trisulphid becomes more soluble. For this reason lead arsenate is probably safer than any of the other arsenical insecticides.”

The influence of arsenic upon the biological transformation of nitrogen in soils, J. E. GREAVES (*Biochem. Bul.*, 3 (1913), No. 9, pp. 2–16; *abs. in Jour. Chem. Soc. [London]*, 106 (1914), No. 616, I, p. 237).—Experiments were conducted to determine the effects of different amounts of sodium arsenate, zinc arsenite, lead arsenate, arsenic trisulphid, and Paris green on the ammonification and nitrification of dried blood in a sandy loam soil rich in calcium and iron, and abundantly supplied with plant food with the exception of nitrogen,

The results varied with the different compounds, but all exerted a stimulating effect in the lower concentrations and a toxic action in the higher. "Measured in terms of their influence upon ammonification and nitrification as it takes place in soil, the toxicity of lead arsenate is the least. Next come zinc arsenite and arsenic trisulphid. The greatest toxicity is exerted by Paris green." The stimulation was greatest with lead arsenate and least with Paris green.

It is concluded in general that water-soluble arsenic may exist in such soils "to the extent of 82 parts per million without entirely stopping ammonification and nitrification. Large quantities of ammonia and nitric nitrogen may be produced in a soil containing 50 parts per million of water-soluble arsenic." It is thought improbable that lead arsenate, zinc arsenite, or arsenic trisulphid "will ever be applied to agricultural soil in quantities sufficient to become injurious to soil bacteria. Paris green may, but the quantity added would have to be large."

Some factors influencing ammonification and nitrification in soils.—I, Influence of arsenic, J. E. GREAVES (*Centbl. Bakt. [etc.]*, 2. Abt., 39 (1913), No. 20-22, pp. 542-560; abs. in *Jour. Chem. Soc. [London]*, 106 (1914), No. 616, I, pp. 236, 237).—The work described in this article has been noted from other sources above.

Cupric treatments and the nitrification of the soil, G. PATUREL (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 34 (1913), No. 23, pp. 711-714; abs. in *Internat. Inst. Agr. [Rome]*, Mo. Bul. Agr. Intel. and Plant Diseases, 4 (1913), No. 8, pp. 1187, 1188).—A study was made of the rate of nitrification in soils of vineyards which had been sprayed with varying amounts of copper salts for the prevention of disease.

The general conclusion was that there is no reason to apprehend injurious results as regards nitrification from the frequent use of such copper sprays. Even in soils containing over 2 per cent of copper salts the nitric nitrogen was still 60 per cent of that in untreated soil, and with 0.1 per cent of copper sulphate the nitric nitrogen rose to 90 per cent of that in untreated soil. Copper salts added to the soil were rapidly converted into insoluble form, and for this reason exerted only a weak inhibitive action on nitrification even when large quantities were used.

Nitrification in acid humus soils, A. PETIT (*Ann. Sci. Agron.*, 4. ser., 2 (1913), II, No. 4, pp. 397, 398).—The author reports finding pronounced evidences of nitrification in a decidedly acid forest soil deficient in lime.

The relation between decomposition of cellulose and the nitrogen economy of nature, II, H. PRINGSHEIM (*Mitt. Deut. Landw. Gesell.*, 28 (1913), No. 20, pp. 295, 296).—This is a second paper on this subject (*E. S. R.*, 28, p. 720), and deals briefly with aerobic and anaerobic nitrogen-fixing bacteria, nitrogen fixation in the presence of nitrates, nitrogen loss and gain with thermophile bacteria, and notes on pure cultures of cellulose bacteria.

Nitrogen accumulation in continuous rye culture, P. EHRENBURG (*Fühling's Landw. Ztg.*, 62 (1913), No. 13, pp. 450-462).—The author calls attention to a field which is said to have produced a slightly increasing crop of rye for many years, with little or no nitrogen fertilization. He explains this on the ground that the nitrogen required for the rye crop was absorbed as ammonia by the soil from the local rainfall, which is said to contain quantities of ammonia combinations, originating from the combustion of large amounts of poor grade coal in the neighborhood.

Nitrogen accumulation in continuous rye culture, F. LÖHNIS (*Fühling's Landw. Ztg.*, 63 (1913), No. 23, pp. 838-841).—The author questions whether the

conclusion of Ehrenberg (see above) regarding the accumulation of nitrogen in the soil from atmospheric sources is warranted.

Ammonia evaporation from soil. O. LEMMERMANN and L. FRESENIUS (*Landw. Jahrb.*, 45 (1913), No. 1, pp. 127-154; *abs. in Ztschr. Angew. Chem.*, 27 (1914), No. 17, *Referatenteil*, p. 154).—Tests of 6 soils, including sandy loam and moor soils, were made to determine the influence of the addition of calcium carbonate on the ammonia absorbing power of the soils. The soils were treated with different amounts of ammonium carbonate and submitted to aeration under various conditions.

Each soil was found to have an individual action regarding the absorption of ammonia, and the effect of calcium carbonate varied with the physical and chemical character of the soils, promoting ammonia evaporation in some, retarding it in others, and in one soil having no effect. In three of the soils it was found that with a large application of ammonium carbonate the absorption of ammonia was promoted by the addition of calcium carbonate, while with a small application it was retarded.

It is concluded that the absorption of ammonia salts depends almost entirely on the exchange of bases of the zeolitic combinations in the soil. This is either promoted, retarded, or not at all affected by the addition of calcium carbonate, according to the chemical character of the soil, and that the effect of calcium carbonate is influenced by the absolute quantity of ammonium carbonate added and by the amount of exchangeable potassium present.

The catalytic power of agricultural soil. H. KAPPEN (*Fühling's Landw. Ztg.*, 62 (1913), No. 11, pp. 377-392).—The author reviews a number of investigations on the catalytic power of soils.

Sterilization by heat and by poisonous substances so as to change the physical and chemical composition of soils was found to reduce greatly the rate of decomposition of hydrogen peroxid, while sterilization in which the physical and chemical composition remained unchanged produced no change in the rate of decomposition. A comparison of the rate of decomposition of compounds, when treated with colloidal substances and with samples of cultivated soils in their natural state, showed a marked similarity. The general conclusion is that although the decomposition of matter in soils is promoted by enzymes and bacterial activity, the real catalytic power of soils is due to the colloids, which through the agencies of physical adsorption of substances on their surfaces and an intermediary reaction, have the power of decomposing these substances without losing their own identity.

It is further concluded that the catalytic power of a soil depends largely on its good physical condition and its alkalinity, and that these factors govern the relations between catalytic power and productiveness of a soil.

The food and habits of life of earthworms in relation to agriculture. E. KEUP (*Mitt. Deut. Landw. Gesell.*, 28 (1913), Nos. 39, pp. 538-542; 40, pp. 552-555; 41, pp. 566-570).—In a review of numerous investigations on the life and activity of earthworms in their relations to agriculture, the author briefly describes the anatomical structure of these animals, their habits, and actions, and sums up their beneficial effect on soils as regards fertility as follows: They prevent the formation of peat bogs and swamps, especially in forests, by destroying the plant residue on the soil surface. Through the taking up and digesting of soil constituents the percentage of fine matter is increased, upper and lower soils are intimately mixed together and with plant food, the soil is loosened and crumbled, bacterial action is favored, the soil is fortified against drought, deep rooting is promoted, plant food is placed in more readily assimilable condition, and in short, the soil is put in better physical and chemical condition for plant growth.

The only injurious effects which are attributed to earthworms are said to be an insignificant danger to ungerminated seeds and a slight injury to potato roots and potted plants.

Soil fatigue, F. T. PERITURIN (*Izv. Moskov. Selsk. Khoz. Inst. (Ann. Inst. Agron. Moscou)*, 19 (1913), No. 4, pp. 1-141, figs. 36).—The author briefly reviews the literature on the subject of tired soils and reports a series of cereal cropping experiments conducted to determine the origin of injurious substances said by American investigators to originate in the soil and cause fatigue.

Three successive growths of oats in distilled water, each of two weeks' duration, showed no difference in weight or external appearance.

Several different kinds of plants were seeded in varying alternations in sand cultures, using clean quartz sand and Hellriegel's nutritive solution. The second seeding in all cases produced a weak growth of poor appearance. Repeated seeding in the same pot brought out abnormal characteristics in all the plants, and plants of the second seeding showed the same poor development when following a first seeding of their own kind as when alternated with plants of different botanical groups. The addition of 15 gm. of clean pulverized charcoal to a pot after the first seeding was followed by normal development of the second seeding. The decrease in yield in the second seeding is attributed in part to the action of the decomposing root residue from the first seeding, and not wholly to the alkalinity of the culture medium.

Growths of wheat and oats from the second of two successive seedings in soil, each grown for six weeks, developed abnormally with greatly decreased yield. Complete fertilization of the soil between seedings decreased the abnormal development very little.

Oats and buckwheat were grown in water cultures, using soil extracts to which the Hellriegel nutritive solution was added. Part of the solutions was used in its original state, part was filtered through charcoal, and part was boiled. The filtered solutions produced normal growths, while the boiled solutions produced both normal and abnormal growths, depending on the solution. The untreated solutions in which there had been no previous growth produced a normal growth.

It is concluded that extracts from soils cropped as indicated probably contain substances injurious to plants which are removed by filtration through charcoal, and that boiling destroys them only in certain soils. No injurious substances were found in soils which had not been cropped with cereals, and it is thought probable that these soil extracts are injurious to plant growth in general.

The Illinois system of permanent fertility, C. G. HOPKINS (*Pop. Sci. Mo.*, 84 (1914), No. 1, pp. 52-63, figs. 5).—In this system "those materials which are naturally contained in the soil in inexhaustible amounts are liberated from the soil and thus made available for crop production; those contained in the air are likewise drawn upon as needed; while those materials which must be purchased are bought and applied in liberal quantities, but in low-priced forms, and then made available on the farm by economic natural methods."

The system involves liberal applications of barnyard manure, ground limestone, and raw rock phosphate, and rotations including a legume to supply nitrogen. The practically inexhaustible supply of potash in the soil is drawn upon to furnish the necessary amounts of this element of plant food. The successful application of the system on a farm of poor gray prairie soil in southern Illinois is described. See also a previous note (*E. S. R.*, 29, p. 623).

Comparative tests of various fertilizers, G. SMETS and E. THOMAS (*Abd. in Zentbl. Agr. Chem.*, 42 (1913), No. 10, pp. 667-669).—Pot tests on corn of

Thomas slag and calcined raw phosphate, phonolite and potassium chlorid, and sodium nitrate, ammonium sulphate, and calcium cyanamid are reported.

The calcined raw phosphate and the phonolite were almost without fertilizing effect. The ammonium sulphate was four-fifths, the cyanamid three-fifths as effective as sodium nitrate.

Experiments with fertilizers in West Prussia, GERLACH (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg*, 5 (1913), No. 5, pp. 335-359).—A number of experiments with a variety of crops on soils of different kinds throughout the Province of West Prussia are briefly reported.

Summarizing the general results for several years it is stated that fertilizers as a rule proved beneficial. Nitrogenous fertilizers were especially effective, but the results also indicated that available potash is lacking in most of the soils.

The use of preservatives with liquid manure rich in nitrogen, D. MEYER (*Illus. Landw. Ztg.*, 33 (1913), No. 91, pp. 823-825).—Four cc. of liquid manure containing 0.778 per cent ($=0.03112$ gm. per flask or 26.8 lbs. per acre) of nitrogen was added to 225 gm. of dry ($=250$ gm. of moist) soil, air was drawn through the flask, and the ammonia so removed was collected in dilute sulphuric acid and titrated.

It was found that the loss of nitrogen was much greater with sandy soils than with loam soils and with dry soils than with moist. With dry sandy soils the loss of nitrogen was 21.95 per cent of that in the manure in the first 48 hours, with moist sandy soil 10.58 per cent, with dry loam soil 11.33 per cent, and with moist loam soil 5.33 per cent. In 48 hours more the loss with moist sandy soil was increased to 18.14 per cent, with moist loam soil to 8.71 per cent.

One hundred cc. samples of the liquid manure were treated with varying amounts of sulphuric acid, phosphoric acid, superphosphate, and gypsum. From 92.8 to 95.9 per cent of the nitrogen of the manure was in form of ammonium carbonate. The sulphuric acid was applied in amounts varying from a little less to a little more than enough to fix the total nitrogen or replace the carbon dioxid present. The liquid was allowed to evaporate slowly to dryness at ordinary temperature. Without treatment there was almost complete loss of the ammoniacal nitrogen. With addition of sulphuric acid equivalent to the total nitrogen there was a loss of 7.27 per cent and with sulphuric acid equivalent to the carbon dioxid only 2.68 per cent. Increasing the acid beyond the equivalents stated reduced the loss still further but not materially. The losses were much greater with phosphoric acid, superphosphate, and gypsum than with sulphuric acid. Over 50 per cent of the nitrogen was lost in case of gypsum. It was about 37 per cent with the largest amount of phosphoric acid used and 27 per cent with the largest amount of superphosphate used.

The use of sulphuric acid is considered the most effective and satisfactory means of preservation.

The industrial synthesis of nitric acid and ammonia, C. MATIGNON (*Rev. Gén. Chim.*, 16 (1913), Nos. 21, pp. 357-365; 22, pp. 381-388).—The progress in devising and perfecting processes for this purpose is reviewed, and the future possibilities of the industry are discussed.

Mustard and buckwheat fertilized with various raw phosphates, P. E. GAL'TSEV and I. V. IAKUSHKIN (*Izv. Moskov. Selsk. Khoz. Inst. (Ann. Inst. Agron. Moscou)*, 19 (1913), No. 1, pp. 193-204, figs. 2; *Iz Rezul't. Veget. Opytov Lab. Rabot*, 8 (1911-12 [pub. 1913]), pp. 193-204, figs. 2).—The action of the various phosphates (Russian) on mustard and buckwheat was compared with the results of previous tests with lupines. The results varied with the different phosphates but there was a certain parallelism between the results with lupines and buckwheat.

Assimilation of reverted phosphoric acid by plants, V. P. KOCHETKOV (*Izv. Moskov. Selsk. Khoz. Inst. (Ann. Inst. Agron. Moscou)*, 19 (1913), No. 1, pp. 205-222, figs. 9; *Iz Rezul't. Veget. Opytov Lab. Rabot*, 8 (1911-12 [pub. 1913]), pp. 205-222, figs. 7).—The results of sand cultures with various phosphates untreated, leached with water, and digested with ammonium citrate were variable and inconclusive.

The German potash salts, LEBERKE (*Pflanzer*, 9 (1913), No. 11, pp. 533-542, pls. 8).—This article discusses the character and extent of the German potash deposits, method of exploitation, manufacture, and use, including statistics of home and German colonial consumption and foreign export.

Comparative fertilizer tests of common salt and potash salt, P. BOLIN (*Meddel. Centralanst. Försöksv. Jordbruksområdet*, 1913, No. 82, pp. 16; *abs. in Zentbl. Agr. Chem.*, 42 (1913), No. 10, pp. 670-673; *Jour. Soc. Chem. Indus.*, 32 (1913), No. 23, p. 1122).—The results of 19 series of comparative tests in different parts of Sweden of equal amounts of sodium chlorid and 37 per cent potash salt applied to oats, hay, kohl-rabi, sugar beets, and fodder beets are reported.

On hay and on oats on moor soils the sodium chlorid was but little less effective in increasing the yield than the potash salt. With kohl-rabi and beets 428 lbs. per acre of salt produced a greater and more profitable increase in yield than 178 lbs. of potash salt. The results are attributed more to the chlorin or general effect of the salts than to the supply of either potash or soda.

Fertilizers, R. E. ROSE and L. HELMBURGER (*Fla. Quart. Bul. Agr. Dept.*, 23 (1913), No. 3, pp. 187-199, 204-209).—An account is given of the fertilizer inspection during 1913, including analyses of fertilizers examined, with notes on laws and regulations and valuation of fertilizers.

Report of analyses of commercial fertilizers (*Louisiana Stas. Fert. Rpt. 1912-13*, pp. 102).—Analyses of 9,230 samples of fertilizers and fertilizing materials inspected during the season of 1912-13 are reported.

Fertilizer analyses, A. J. PATTEN, W. C. MARTI, A. K. HART, and O. F. JENSEN (*Michigan Sta. Bul.* 272, pp. 3-55).—This is a report of the usual kind, giving results of analyses and valuations of fertilizers inspected in Michigan in 1913. The text of the State fertilizer law as amended in 1913 is also given.

The amended law defines the term "commercial fertilizer," including specifically limestone or lime rock. It also more clearly prescribes the form and contents of the certificate of analysis, etc., to be filed with the secretary of state and attached to the bags or packages of fertilizers.

Analyses of commercial fertilizers, B. L. HARTWELL ET AL. (*Rhode Island Sta. Insp. Buls.*, 1911, Sept., pp. 11; Oct., pp. 8).—Analyses and valuations of fertilizers inspected during the latter part of 1911 are reported.

Commercial fertilizers in 1912-13, G. S. FRAPS (*Texas Sta. Bul.* 160, pp. 5-33, figs. 2).—Analyses and valuations of fertilizers inspected during the season of 1912-13 are reported, with collateral information regarding fertilizers and fertilizer inspection, and a list of registered brands is given. The consumption of fertilizers in the State during the period covered by the inspection is estimated to have been 75,500 tons.

AGRICULTURAL BOTANY.

Applied botany for the colonies, M. DUBARD (*Botanique Coloniale Appliquée. Paris*, 1913, pp. VI+347, figs. 146).—In this book the author has departed from the usual arrangement of the material, and instead of describing plants according to their systematic sequence he has grouped them with reference to their

more important products, thus bringing together plants of widely divergent botanical relationships that are closely allied so far as their uses are concerned.

After giving general directions for the preparation and care of material for study, the author gives chapters on the microscopic studies of the principal substances found in plant cells, plant structures, etc. The principal proportion of the book is taken up with studies on starches, tropical woods, their character and uses, fibers, and secretory substances such as resins, rubbers, etc.

Biology of plants, F. W. NEGER (*Biologie der Pflanzen auf experimenteller Grundlage. Stuttgart, 1913, pp. XXIX+775, figs. 315*).—The author discusses at considerable length the theory of adaptation, and treats of adaptation of plants to light, temperature, water, mechanical stimuli, edaphic adaptations, symbiotism, special adaptations for propagation, etc., the subject being largely presented in such a manner that the book should be of special interest to students of ecology.

Researches on irritability of plants, J. C. BOSE (*London, New York, and Bombay, 1913, pp. XXIV+376, figs. 190*).—The author presents the results of his investigations on the irritability of plants, using new electrical devices for recording that are considered superior to the methods formerly applied.

The two forms of apparatus are called the oscillating recorder and the resonant recorder. In the former the recording surface is so oscillated as to bring it in contact with the recording point. In the second the writing point is made to vibrate at required frequencies, making an intermittent contact with the recording plate. Both when tested gave satisfactory records of response to stimuli of various sorts.

The author claims from a survey of the response of living tissues that there is hardly any phenomenon of irritability observed in the animal which is not also found in the plant, and that various manifestations of irritability in the plant have been shown to be identical with those in the animal.

Chemical and physical changes in geotropic stimulation and response, EVA O. SCHLEY (*Bot. Gaz., 56 (1913), No. 6, pp. 480-489, figs. 6*).—In view of the effect of acidity on the absorption of water and on the growth rate, the author made a study of the concave and convex halves of geotropically stimulated and responding organs for difference in acidity, and incidentally for other features, such as the sugar content.

It was found that the acidity of the growing shoot is greatest at the tip and decreases downward. The relative acidity of the two flanks of the geotropically stimulated shoots changes during presentation and reaction time. The increase of acidity does not parallel the relative rate of growth on the two flanks. Several plants examined were found to develop in neutral solution a chromogen which acted as a delicate acid-alkali indicator. The percentage of dry weight was found to be greatest on the concave side of the stimulated organs.

Acidity, gaseous interchange, and respiration of cacti, H. M. RICHARDS (*Carnegie Inst. Washington Year Book, 11 (1912), pp. 65, 66*).—An investigation has been made of the respiration of cacti and the phenomena related thereto under various external conditions. The effects of temperature changes and wound reaction were studied, and parallel with these experiments a series of experiments were conducted to determine the respiratory quotient of cacti.

In general it was found that the respiration of the young joints is far higher than that of the older but turgid tissue, while that of the latter greatly exceeds the respiration of the mature but inactive plant. The gas interchange was found to be different in the young and old shoots. The younger ones approximated more nearly the usual absorption of oxygen and evolution of carbon dioxide, while the older joints showed a larger use of oxygen, which is said

to be characteristic of succulent plants. The acidity of plants was found to increase in the absence of oxygen and to decrease with an increased supply in the atmosphere. The experiments showed conclusively that the diminishing acidity from early morning to late in the afternoon is a combined temperature and light reaction.

Influence of light and of shade on shoots of woody plants, H. FARENHOLTZ (*Bot. Centbl., Beihefte, 31 (1913), 1. Abt., No. 1, pp. 90-118*).—Giving results of a study of light as influencing development of branches and seedlings of beech, elm, and other forest trees, the author states that the anatomical structure of the branches is altered in several respects under the influence of different illuminations. A number of differences of anatomical response are noted between the effect on long and that on short branches in this respect, while comparatively small differences appear in twigs of the seedlings. The latter are said to show, when grown in light, similarities to shade grown branches of older plants of the same kind. Beech buds grown in sunshine are said to show peculiarities as regards number, size, and internal structure, as compared with those produced in shade.

A bibliography is appended.

Influence of shading on composition of tobacco, A. STUTZER and S. GOR (*Biochem. Ztschr., 56 (1913), No. 3, pp. 220-229*).—Experiments described with tobacco grown under controlled conditions are claimed to show that a large percentage of nicotin can be produced by abundant sunlight, high temperature, liberal nitrogen manuring, and sparing use of water in the soil; also that direct sunlight favors a high potassium, but a low chlorin, content.

Sensitive life of *Asparagus plumosus*.—A morpho-physiological study, F. C. NEWCOMBE (*Bot. Centbl., Beihefte, 31 (1913), 1. Abt., No. 1, pp. 13-42*).—The author concludes a somewhat detailed summary of results obtained from a study of the various tropisms of *A. plumosus nanus* by stating that the biological significance of various characteristics of this plant when grown in darkness, such as the removal of inhibition of elongation of the aerial shoot, the cessation of twining, the failure to unfold lateral buds, and the absence or stunted growth of needles, may be referred to the conservation of building material. It is thought that the significance of the bending to a horizontal position of the upper portion of the aerial shoot from the rhizome and of the seedling may be that it brings the assimilating part of the plant into a more favorable position with respect to light.

An examination into experiments on the action of atmospheric electricity on plants, P. LESAGE (*Compt. Rend. Acad. Sci. [Paris], 157 (1913), No. 18, pp. 784-787, fig. 1*).—The investigations of Grandeau, who found that plants grown under wire cages and submitted to the influence of atmospheric electricity were retarded in growth, are reviewed. The author grew cress and *Datura* under wire cages, under a cage of silk thread of the same diameter and mesh as the galvanized iron wire used, and in the open.

The experiments with cress did not give any striking results, although the plants grown under both cages were somewhat different from those cultivated in the open. In the case of the *Datura*, the plants of which were grown from July to September, those under both cages were decidedly reduced in size, the ones under the wire cage, however, being slightly better developed than those under the silk cage.

During the progress of these investigations the author examined other phenomena connected with the differences under the cages, and reports that evaporation was greatly reduced under the protection of the cages.

Chemical effects of radiant energy in plant processes, H. A. SPOEHR (*Carnegie Inst. Washington Year Book, 11 (1912), pp. 63-65*).—In continuation of previous studies (E. S. R., 27, p. 521), the author reports on the effect of ultraviolet light on the decomposition of carbon dioxide, etc.

Contrary to the statement of Usher and Priestley (E. S. R., 25, p. 634), carbon dioxide was not reduced to formaldehyde under the action of ultraviolet light. It was found, however, that formaldehyde was formed when a solution of potassium carbonate containing colloidal platinum and through which carbon dioxide was allowed to pass was exposed to ultraviolet light.

A number of plant acids were under observation, having been exposed to sunlight for a year. The products formed by this long insolation are being investigated. It has been found that acetic, glycolic, propionic, malic, tartaric, and citric acids are decomposed in the light with the liberation of considerable quantities of carbon dioxide. Formaldehyde is also formed, and, in the case of the higher hydroxyacids, nonvolatile substances are produced which reduce Fehling's solution. It was found in general that the acids were decomposed much more easily in the form of a salt than as the free acid. Formic acid was not found to yield any reduction product.

Influence of colloids on microbiological processes, N. L. SÖHNGEN (*Centbl. Bakt. [etc.], 2. Abt., 38 (1913), No. 21-25, pp. 621-647, figs. 4*).—From several series of studies the author concludes that adsorption phenomena are of considerable significance in microbiological processes. Colloidal silicic acid in the Beijerinck culture medium promoted in marked degree the fixation of nitrogen by *Azotobacter*, as did also raw humus and colloidal oxides of iron and aluminum. Alkali salts of humus acids hinder alcoholic fermentation, which, however, is favored by the presence of turf, filter paper, and garden soil. Oxidation of petroleum by bacteria is considerably increased by the addition of colloidal oxides of iron and silica.

The behavior of micro-organisms in brines, G. J. PEIRCE (*Carnegie Inst. Washington Year Book, 11 (1912), pp. 52, 53*).—The author has been observing for three years the micro-organisms occurring in brines of salt works along the shores of San Francisco Bay. The flora was found to vary with the concentration of the brine, but although the brines were rich in organic matter it was impossible to secure an organic analysis. Many of the brine organisms were found to be more or less completely saprophytic, but their relations to the organic constituents of the brines could not be determined.

Alterations in woody tissues and bacterial action in Salton water, M. A. BRANNON (*Carnegie Inst. Washington Year Book, 11 (1912), pp. 51, 52*).—A study was made of stems of mesquite (*Prosopis juliflora*) and creosote bush (*Covillea tridentata*), together with the water occurring in Salton Sea, to determine the cause of certain changes that have been observed.

Chemical analyses of the water did not reveal any free chemical that could injure the plants, but it became evident that the changes were due to bacterial action. Later it was proved that both the reduction of the sulphates and the hydrolysis were due to the action of different groups of bacteria. The agents that hydrolyzed the cell walls were formed by bacteria belonging to the Amylobacter group.

The effects of soluble humates on nitrogen fixation and plant growth, W. B. BOTTOMLEY (*Gard. Chron., 3. ser., 54 (1913), No. 1400, pp. 295, 296, figs. 3*).—In a lecture delivered before the Horticultural Club the author described pot experiments which seemed to demonstrate that when sterilized peat, saturated with active cultures of nitrogen-fixing organisms, is used to inoculate ordinary soil, nitrogen fixation takes place much more rapidly than where liquid cultures of the organisms are added directly to the soil.

Summarizing the results of his investigations it is said that the addition of sterilized and inoculated peat adds active nitrogen-fixing organisms to the soil under suitable conditions for nitrogen fixation. It stimulates the nitrogen fixers already in the soil, adds direct plant food, promotes root development, and improves the mechanical condition of the soil.

The inulin metabolism of *Cichorium intybus*.—II, Origin and storing of inulin, V. GRAFE and V. VOUK (*Biochem. Ztschr.*, 47 (1912), No. 3-4, pp. 320-330).—Continuing former work (E. S. R., 28, p. 821), the authors report that inulin appears to play an important part in the assimilation of carbon dioxide by chicory, that no difference in content of inulin or sugar as between forenoon and afternoon is noted, and that in the earlier course of root development an increase of inulin is noted in relation to a decrease of reducing sugars.

The inulin metabolism of *Cichorium intybus*, III, V. GRAFE and V. VOUK (*Biochem. Ztschr.*, 56 (1913), No. 3, pp. 249-257).—Summarizing this contribution in connection with previous work (see above), the authors state in addition to former conclusions that inulin dissolved in cell sap also serves as a protection from cold.

The physiological significance of anthocyanin in *Hedera*, F. TOBLER (*Festschrift 84. Versamml. Deut. Naturf. u. Ärzte von der Med. Naturw. Gesell. Münster, 1912*, pp. 218-221).—The author cites observations of his own on *Hedera*, claimed to show that the capability to form anthocyanin in a plant is related to its degree of adaptation to a cool or cold climate.

Injury to plants by smoke gases and dust, J. HASENBÄUMER (*Festschrift 84. Versamml. Deut. Naturf. u. Ärzte von der Med. Naturw. Gesell. Münster, 1912*, pp. 123-147).—Comparative figures regarding plants grown in smoke or gases (as from coke works) are cited to show the unfavorable effects thereof on development and content in numerous cases including widely separated species. The part played by wind in this connection is also discussed.

Injury to vegetation near cyanamid works, G. AMPOLA and A. VIVENZA (*Ann. R. Staz. Chim. Agr. Sper. Roma*, 2. ser., 6 (1913), No. 2, pp. 77-115).—A study of the various degrees of injury to vegetation observed around chemical works near Terni, Italy, is said to show that this is due to dust and vapors given off, in particular sulphur dioxide, which is claimed to be injurious when present in very small proportions.

Concrescences in forest trees, ZAMETZER (*Mitt. Bayer. Bot. Gesell.*, 3 (1913), No. 1, pp. 8, 9, pl. 1; *abs. in Bot. Centbl.*, 122 (1913), No. 20, pp. 468, 469).—Illustrations and descriptions are given of two cases in each of which two vigorous young red beech trees are united into one cylindrical trunk several meters above the ground. This is thought to be the result of abrasion due to wind movements when weighted with snow.

The group origin of species, H. DE VRIES (*Gruppenweise Artbildung unter spezieller Berücksichtigung der Gattung Enothera*. Berlin, 1913, pp. VIII+365, pls. 22, figs. 121; *rev. in Nature [London]*, 92 (1913), No. 2301, pp. 395, 396).—This book, which is considered an outgrowth and development of the author's mutation theory, marks an important advance in our knowledge of the hereditary behavior of the evening primroses and also coordinates and develops his views on the general subject of heredity and its relation to mutation.

The author adheres to the view that characters which are independently inherited must be represented by separate structures (pangens) in the cell. These are not considered simply present or absent from the cell but may exist under three conditions, active, inactive, and labile.

In addition to the theoretical discussion, he shows that new and constant races frequently result from crossing. Some of these races, however, are not

Mendelian recombinations but possess many characters which have been modified.

The author considers that mutation as a process is not to be confounded with the mere recombinations of unit characters, and that various types of hereditary behavior exist, only occasional characters showing the Mendelian type of segregation.

Note on gametic reduplication in *Pisum*, CAROLINE PILLEW (*Jour. Genetics*, 3 (1913), No. 2, pp. 105, 106).—An account is given of crosses made between a tendrilled variety of peas having wrinkled seed and a round-seeded acacia form, the object of the cross being to see whether among the gametes of F_1 repulsion between the factors, tendrils, and round seed would occur. The F_2 seeds were sorted into round and wrinkled, and the result showed that repulsion occurred. It is considered to be presumably only partial, but the proof is thought to be beyond the scope of practical experiment on account of the large number of plants involved.

In view of the possibility that factors other than roundness might couple with the factor for tendril, crosses were made in which various factors were introduced with the tendril and acacia characters, but no signs of coupling or repulsion were observed in F_2 from such crosses.

A quantitative study of the factors influencing the weight of the bean seed.—I, Intra-ovarial correlations, J. A. HARRIS (*Bot. Centbl., Beihefte*, 31 (1913), 1. Abt., No. 1, pp. 1–12, pls. 4).—This paper, the first of a series dealing with the physiology of seed production, gives data regarding the characteristics of the pod and the weight of the bean seed.

It is stated that the correlation between such weight and the number of ovules per pod is so low as to be practically negligible. That between number of seeds matured per pod and seed weight is low but decided, being always negative. The chances for an ovule to develop into a seed are generally greater toward the stigmatic end. The weight of the seed shows the same general kind of correlation, but this finally becomes less marked as the distal end is approached.

The cultural bud mutations of tuberous *Solanums*, E. HECKEL (*Rev. Sci. [Paris]*, 51 (1913), II, No. 19, pp. 577–582).—The author describes the work which has been done in inducing what he calls bud mutations in tuberous *Solanums*, and interprets the results obtained in relation to the criticism that such transformations are not true mutations.

On the presence of connecting threads in graft hybrids, MARGARET HUME (*New Phytol.*, 12 (1913), No. 6, pp. 216–221, fig. 1).—A study was made of the graft hybrids *Cytisus adami*, *Solanum tubingenense*, and *S. kœlreuterianum* with a view to determining the presence of connecting threads between the different elements.

From the experiments the author draws the conclusion that if Baur's hypothesis that graft hybrids really are periclinal chimeras is true, and there is every reason to believe that it is, there is no doubt that genetically unrelated tissues can be joined by connecting threads. The threads arise secondarily, since it is supposed that the naked cytoplasm of the two components does not come into contact.

Anatomy as a means of diagnosis of spontaneous plant hybrids, R. HOLDEN (*Science, n. ser.*, 38 (1913), No. 991, pp. 932, 933).—From a study of forms of *Betula pumila* from the Arnold Arboretum and of a variety of *Equisetum*, the author is led to the conclusion that spontaneous hybrids are of common occurrence and that they can be clearly diagnosed as hybrids by an investigation of their vegetative and reproductive internal anatomy. It is believed that an in-

vestigation of the anatomy of recognized or cryptohybrids is likely to be of great value from the genetical standpoint and will in all probability lay bare the real foundation of the so-called mutation hypothesis of De Vries.

Mistletoe infection in relation to classification, C. VON TUBEUF (*Centbl. Bakt. [etc.]*, 2. Abt., 36 (1913), No. 19-25, pp. 508-531, pl. 1; *abs. in Ztschr. Landw. Versuchsw. Österr.*, 16 (1913), No. 4, p. 477).—The results are given in detail and in tabular form of infection experiments made with several species of mistletoe on numerous hosts differing widely in relationship. See also a previous note (E. S. R., 29, p. 243).

FIELD CROPS.

Agriculture in Abyssinia.—I, Soils and crops, A. KOSTLAN (*Tropenpflanzer, Beihefte*, 14 (1913), No. 3, pp. VII+183-250, figs. 31).—This publication gives an account of aboriginal methods and customs of agricultural practice in Abyssinia under the headings of climate, soil, implements, fertilizers, irrigation, seeds, seed selection and care, cultivation of cereals, legumes, oil-producing plants, root crops, tobacco, coffee, *Rhamnus prinoides*, *Catha edulis*, fiber plants, sugar-producing plants, vegetables, and fruits. A bibliography is appended.

Experiments with wheat, oats, and barley in South Dakota, M. CHAMPLIN (*U. S. Dept. Agr. Bul.* 39, pp. 37, pl. 1, figs. 11).—This bulletin discusses two essential requirements for crop improvement, viz, better varieties and better seed, and presents the results of studies pertaining thereto in regard to wheat, oats, and barley as experimented with at Eureka, Highmore, Cottonwood, and Brookings, in cooperation with the South Dakota Experiment Station.

Descriptions of the leading varieties of each kind of cereal and of cultural methods are given. Analyses on the composition showed the protein content of the several varieties of wheat to range from 17.69 to 21 per cent, of oats from 14.63 to 18.56, and of barley (6 rowed) from 16.7 to 18.8 and (2 rowed) from 16.7 to 19.7 per cent.

From the results of these experiments, which have been carried on since 1903 and include variety tests, the following varieties are recommended for cultivation in that State: (1) Wheat: Kubanka durum (C. I. No. 1440), Haynes Blue Stem (Minn. No. 169), Red Fife (C. I. No. 3081), and Fife (Minn. No. 163). (2) Oats: Swedish Select (C. I. No. 134) and Sixty-Day (C. I. No. 165). (3) Barley: (a) For the eastern district: Manchuria (Minn. No. 105) and Odessa (C. I. No. 182). (b) For the central district: Hannchen (C. I. No. 531). (c) For the western district: Gatami (C. I. No. 575), Mariout (C. I. No. 261), and related varieties.

[Annual report of the divisions of agronomy and fiber] (*Philippine Agr. Rev. [English Ed.]*, 5 (1912), No. 13, pp. XXI-XXIV, XXXVII-XLVI).—These pages contain brief notes on the work in progress with rice, Rhodes grass, Guinea grass, Japanese cane, sorghum, cowpeas, abaca, maguey, sisal, kapok, and cotton during the year.

Report of government agriculturist and botanist, H. G. MUNDY (*South. Rhodesia Rpt. Dir. Agr.*, 1911, pp. 30-38).—This report gives brief notes on trials of alfalfa, castor beans, cassava, sugar cane, Napier's fodder, hemp, sisal, cotton, flax, ramie, rescue grass, sainfoin, cowgrass clover (*Trifolium perenne*), sulla, tall oat grass, Yorkshire fog (*Holcus lanatus*), perennial rye grass, Paspalum, sheep's burnet (*Sanguisorba minor*), sheep's parsley (*Petroselinum sativum*), cocksfoot, awnless brome, Toowomba canary grass (*Phalaris bulbosa*), Egyptian clover, Florida beggar weed, arrowroot, soy beans, pota-

toes, linseed, peanuts, dry-land rice, maize, oats, wheat, stock melon. Boer manna, teff grass, velvet beans, Kafir beans, root crops, chicory, and buckwheat.

Report of the agriculturist and botanist, H. G. MUNDY (*South. Rhodesia Rpt. Dir. Agr.*, 1912, pp. 33-40).—This report gives notes on a continuation of work mentioned above with additional data on barley, monkey nuts, and rye.

The breeding work at Svalöf, C. FRUWIRTH (*Monatsh. Landw.*, 6 (1913), No. 7, pp. 193-207).—This paper describes the work in plant breeding that is being done at this Swedish station, and discusses some results and the principles involved.

Experiments in dry farming (*Agr. Jour. Union So. Africa*, 5 (1913), No. 6, pp. 925-930).—Here are given in tabular form data on results of growing the following crops in 1912 at the dry-land station at Lichtenburg: Soy beans, potatoes, maize, teff grass, flax, peas, millet, sunflower, cowpeas, vetch, lupines, velvet beans, Kafir beans, barley, wheat, rye, peanuts, alfalfa, sainfoin, *Phalaris bulbosa*, cotton, coriander, ginger, clovers, beggar weed, *Bromus inermis*, forest trees, apples, and Spanish reeds.

Dry land pastures (*Rhodesia Agr. Jour.*, 10 (1912), No. 2, pp. 244-246).—This article mentions as desirable *Paspalum dilatatum* as a summer pasture grass, and *Phalaris bulbosa* as a winter pasture grass, both having given good results on dry lands in Rhodesia.

On the appropriation of nitrogen by legumes, A. HERKE (*Kísérlet. Közlem.*, 15 (1912), No. 5, pp. 790-800).—Through his experiments the author concludes that when the soil contains sufficient assimilable nitrogen the presence of nodules on the roots has no influence on the nitrogen content of lupines. When the soil is poor in nitrogen the presence of nodules increases the absolute as well as the percentage of nitrogen content of the plant. It is noted that the greater the percentage of nodules to plant, by weight, the greater is the percentage of nitrogen in the plant (with nodules removed), but when the percentage of nodules becomes large the nitrogen content of the plant does not increase by further growth of the nodules. It was also determined that the dry matter, the nodule growth, and the nitrogen content of the plant may continue to increase after the flowering stage. The percentage of nitrogen in the dry matter of the nodules varied from 5 to 7 per cent, and 57.43 per cent of this nitrogen was soluble in water.

The action of sulphur as a fertilizer, M. A. DEMOLON (*Sta. Agron. Aisne Bul.*, 1912, pp. 33-41).—Results of experiments are given in which flowers of sulphur at the rate of 10 gm. per square meter increased the yield of rutabagas, parsnips, and beets. The applications of sulphur to the soil seemed to give rise to slightly increased quantities of sulphate. Sulphur applications at the rate of 100 kg. per hectare (89 lbs. per acre) increased the yields of potatoes, but not of carrots.

The cultivation of cereals with the aid of new appliances and by new methods, C. KLAUS (*Landw. Hefte*, 1913, No. 22, pp. 48, figs. 5).—The author describes and discusses the use of recently introduced machines and appliances for securing the most perfect seed bed, as well as methods of hilling, drilling, and seeding in furrows. Some results of recent experimental work are quoted in discussing the practicability of these methods.

[Alfalfa production] (*Ann. Rpt. Ill. Farmers' Inst.*, 17 (1912), pp. 173-205, 348-353, figs. 2).—In this article A. P. Grout, G. F. Tullock, and others relate their experiences in producing alfalfa in various parts of Illinois and on several soil types, ranging from heavy rich bottom and drained lands to the light, poor soils of the State. Two papers are included, The Value of Alfalfa on Average Illinois Farms, by A. N. Abbott, and How To Secure a 95 per cent Perfect Stand of Corn, by F. I. Mann.

A drought-resisting adaptation in seedlings of Hopi maize, G. N. COLLINS (*U. S. Dept. Agr., Jour. Agr. Research, 1 (1914), No. 4, pp. 293-302, pls. 4, figs. 2*).—This paper discusses the morphology of the maize seedling and ascribes the value of the Hopi variety as a drought-resistant crop to the fact of the elongation of the mesocotyl.

In laboratory studies it was found that Navajo maize seedling appeared at the surface when the seed was planted to a depth of 32 cm. (12.5 in.) or less, Boone County White planted at the depth of 20 cm. or less, and Chinese maize at 10 cm. or less. In the field it was found that the Indians in New Mexico and Arizona had often planted to a depth of 25 cm.

"A study of the varieties grown by the Hopis and other agricultural Indians shows that these varieties possess two special adaptations: (1) A greatly elongated mesocotyl that permits deep planting, and (2) the development of a single large radicle that rapidly descends to the moist subsoil and supplies water during the critical seedling stage."

A bibliography is appended.

Influence of distance of planting on the yield and nutritive value of fodder corn, J. WEISER and A. ZAITSCHEK (*Kisérlet. Közlem., 15 (1912), No. 4, pp. 543-617, fig. 1*).—A thin stand yielded somewhat more protein and fat than close planted corn. The digestibility seemed to be about the same in both cases. In a wet season the close planted corn gave the higher yield, while in a dry season the reverse was true. In a fermentation test the fodder from the thin stand suffered greater loss than the thick stand product. Late cutting of the thin stand caused greater difficulty in preparing the stubble for the next crop.

The influence of K-P-N on the growth and production of corn, T. N. VIBAR (*Philippine Agr. and Forester, 1 (1911), No. 10, pp. 175-187*).—The author surveys earlier work in the United States on this subject and gives results of his own investigations. Methods are given of soil preparation, cultivation, and harvesting in regard to the 9 plats. The results showed the fertilizers to rank in the following order: Kainit, basic slag, with tankage of least value, when applied singly; when 2 were combined the order of rank was tankage and basic slag, tankage and kainit, and kainit and basic slag. The combination of the 3 fertilizers gave the greatest increased gain, viz, 475.86 kg. of husked corn per hectare (425 lbs. per acre).

Experimental hybridization of cotton, T. THORNTON (*Dept. Agr. Trinidad and Tobago Bul. 11 (1912), No. 70, pp. 100-102*).—The results obtained by crossing varieties of cotton showed increased yields for the first generation. With this point in view a method is described by which a laborer can readily be trained to pollinate from 300 to 360 plants per day, thus producing hybrid seed for the following season at a slight cost in comparison with the expected increased yield of the succeeding crop.

Distribution of cotton seed in 1914, R. A. OAKLEY (*U. S. Dept. Agr., Distribution of Cotton Seed in 1914, pp. 16*).—This publication announces details as to the distribution of cotton seed by this Department in 1914, includes an introductory statement by O. F. Cook explaining how the seed may be utilized to the best advantage by the farmer, and describes 7 varieties of cotton, giving their origin and adaptation.

Fiber plants, J. BEAUVÉRIE (*Les Textiles Végétaux. Paris, 1913, pp. XIII+730, figs. 290*).—The first of the 3 parts of this book treats of morphological, anatomical, botanical, and physical and chemical characters of fiber plants in general, and of retting, methods of investigations, and classification of fibers. The second and third parts treat of the characteristics, varieties, culture, diseases, and enemies of the fiber, and the retting and uses of each of the following

families of fiber plants: Hemp, ramie, stinging nettle, flax, jute, cotton, more than 10 other Malvaceæ, *Abroma augusta*, kapok, Papilionaceæ, Boraginaceæ, Asclepiadaceæ, Apocynaceæ. *Phormium tenax*, yuccas, aloes, Sansevieria agave, sisal, henequin, abaca, *Ananassa sativa*, members of Gramineæ, Cyperaceæ, Typhaceæ, Naiadaceæ, and palms.

A bibliography of 676 publications is appended.

On the manuring of mangels, J. PORTER (*Herefordshire County Council Farmers' Bul.* 3, 1910, pp. 4).—Results obtained in these experiments showed that nitrogen supplied from two sources could be better appropriated by mangels than when supplied in one form (sulphate of ammonia). Superphosphate gave better results than any other single class of phosphates. Muriate of potash gave better results than sulphate of potash, but when salt was added to the complete mixture of artificials, sulphate of potash showed the slightly better results. Salt added to the complete fertilizer produced an average increase in yield of 3 cwt. per acre.

"The following mixture per acre has given the greatest yield: One cwt. nitrate of soda, applied as a top dressing; and 1 cwt. sulphate of ammonia, 4 cwt. superphosphate, $\frac{3}{4}$ cwt. sulphate of potash, and 3 cwt. of salt, applied at planting time."

Spanish peanuts, A. H. WRIGHT (*Oklahoma Sta. Circ.* 19, pp. 4).—Notes on the production and handling of the peanut crop in Oklahoma, with a list of dealers in peanut machinery, are given.

Pifine and the Southdown feed industry (*Modern Sugar Planter*, 43 (1913), No. 29, pp. 2-5, figs. 4).—This article describes the methods used in the cutting, handling, and kiln drying of the pifine grass (*Panicum hemitumum*), which grows in abundance on the wet prairies of Louisiana. This grass, heretofore considered useless, when made into hay was found to analyze 4.1 per cent moisture, 8.35 per cent protein, 1.69 per cent fat, 36.36 per cent crude fiber, 23.28 per cent pentosans, 6.78 per cent ash, and 19.44 per cent undetermined. When dried it is ground and 22 parts mixed by weight with corn-and-cob meal, blackstrap molasses, and cotton-seed meal 50:20:8.

Experiments on the germination of seeds of *Poa pratensis*, S. TOMKA (*Kísérlet. Közlem.*, 15 (1912), No. 4, pp. 618-623).—It was shown by tests that these seeds germinated within a range of temperature reaching from 5 to 35° C.

Additional knowledge on the germination of *Oryza sativa*, M. AKEMINE (*Österr. Bot. Ztschr.*, 63 (1913), No. 5, pp. 194-200).—From various experiments conducted in 1910 and 1911 to study the method of germination of the rice kernel with regard to whether the radicle or the plumule appears first, the author concludes that a healthy rice kernel presents the plumule first under normal conditions, and that apparently the radicle will be presented first only in an abnormally dry medium.

Seed selection, S. L. WRIGHT (*Rice Jour. and South. Farmer*, 16 (1913), No. 8, p. 6).—This article describes 3 varieties of rice, viz, Blue Rose, Louisiana Pearl, and Early Prolific, that have been produced by seed selection. These varieties are of the crystal berry type, differing from the Honduras and Japanese types, and are said to be heavy yielders with exceptionally strong straw and of rapid, vigorous growth.

The cultivation of rice with the help of machines, F. MAIN (*Jour. Agr. Trop.*, 12 (1912), No. 137, pp. 321-325; *abs. in Internat. Inst. Agr.* [Rome], *Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 2, pp. 209, 210).—It is here noted that success has attended the mowing of weeds in rice fields under water and sowing the seed directly in the field later. This avoids the labor of transplanting. Cutting the weeds and reeds under water results in their

asphyxiation and rapid decay. It is also stated that normal rice fields have been plowed successfully by machinery.

Investigations on the influence of injury and the loss of leaves of rye on the development of the spikes and kernels, O. SCHLUMBERGER (*Arb. K. Biol. Anst. Land u. Forstw.*, 8 (1913), No. 5, pp. 515-551, figs. 14).—Leaves of rye plants were removed by scissors and others slit into approximately 3 parts with a needle at 2 periods of growth, at the commencement of the shooting stage and at the beginning of the flowering stage. The effects of these treatments on the quality (size) and quantity (weight) were observed.

Either treatment had little influence on the kernel or head when given before the shooting stage, but when given just before the flowering stage the injury was considerable. The injury by removing all of the green leaves at the second period was scarcely more than by the removal of only the 2 youngest leaves. Slitting the leaves caused injury, but in much less degree than did removal. In general the injury was much greater to the kernels at the extreme ends of the heads than to those located within the middle third. The quantitative injury to the kernels was relatively greater than the qualitative injury in all cases. Chemical analysis showed practically no difference in the kernels from the different treatments.

The influence of the previous crop on the yield of rye, J. VON LENTS (*Illus. Landw. Ztg.*, 32 (1912), No. 78, p. 725, fig. 1).—Grain yields were produced of 1,822 kg. per hectare (1,621 lbs. per acre) following summer fallow. When lupines were plowed under in the flower, pod, and seed stages, the succeeding rye crops were 2,942, 2,503, and 1,844 kg., respectively. With barley as a previous crop the yield was 1,142 kg.

The varieties of soy beans found in Bengal, Bihar, and Orissa, and their commercial possibilities, E. J. WOODHOUSE and C. S. TAYLOR (*Mem. Dept. Agr. India, Bot. Ser.*, 5 (1913), No. 3, pp. 103-176, pls. 5).—The authors discuss the varietal characteristics, types, distribution, cultivation, yield, value, and uses of some soy beans found in cultivation in Bengal. Chemical analyses show the nitrogen content to range from 4.73 to 7.67 per cent, according to type. The highest oil content reported was 16.28 per cent.

Cambodia soy beans (*Agr. Prat. Pays Chauds*, 12 (1912), No. 116, p. 411; *Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 2, p. 210).—It is noted that soy beans have been successfully grown in Cambodia, Indo-China, containing 41.6 per cent of protein and 18.6 per cent of fat.

Soy beans—Why not? A. BUNN (*Country Gent.*, 78 (1913), No. 31, pp. 1138, 1139, fig. 1).—This article gives the results of some tests in Pennsylvania of soy bean varieties in regard to frost resistance.

Haberlandt (yellow) and Wilson (black) lost only 5 per cent of seed by remaining in the field during the winter, while other varieties lost as high as 60 per cent. "Volunteer seedlings in 1912 and 1913 were in excellent condition, without exception, at oats plowing, which is about the middle of April."

Frost-resisting soy beans, A. BUNN (*Country Gent.*, 78 (1913), No. 44, p. 1614, fig. 1).—In this article the author relates his experience with Sable, Haberlandt, and Peking, 3 varieties of soy beans that resumed growth and made good yields after being cut down by a late frost. It is noted that when soy beans were planted with a grain drill as large yields of hay and grain were obtained, and with much less expense, as when planted in rows and cultivated.

The influence of phosphoric acid on the growth and development of sugar beets, H. WILFARTH, H. ROEMER, and G. WIMMER (*Ztschr. Ver. Deut. Zucker-indus.*, 1912, No. 680, pp. 1037-1107; *Bl. Zuckerrübenbau*, 19 (1912), Nos. 21,

pp. 330-335; 22, pp. 345-350; 23, pp. 361-366).—This article gives the results of a pot experiment in which phosphoric acid was used in various quantities, classed as insufficient, possibly sufficient, normal, and surplus, and combined in each case with 3 different amounts of nitrogen, designated as normal, heavy, and very heavy applications. Sugar beets were grown under these manurial applications in both moist and very moist soil conditions.

The largest average yield of beets was obtained with the normal application of phosphoric acid combined with the very heavy use of nitrogen. The analytical data show the roots to contain the highest amount of phosphoric acid where the largest amounts of both phosphoric acid and nitrogen were applied, and the largest amount of nitrogen when grown with the lowest application of phosphoric acid plus the largest application of nitrogen. The moisture content of the soil showed little influence on these figures. The sugar content of the beets was highest with the lowest amount of nitrogen combined with the 3 largest amounts of phosphoric acid, being 18.29, 18.28, and 18.3 per cent, respectively. Additional soil moisture seemed to cause a decrease in sugar content.

The percentage of pulp decreased with the increased applications of phosphoric acid up to the normal application, then increased, while in the very moist soil fluctuating results were obtained. With a small amount of nitrogen the ash and nitrogen-free pectin increased with the increase of phosphoric acid, while with the larger amounts of nitrogen the pectin content was greatest where the extremes of phosphoric acid application were made. Increased soil moisture had little influence on these results. Phosphoric acid seemed to have little influence on the content of invert sugar under any of the given conditions.

The most favorable manurial condition for top development seemed to be with the normal applications of nitrogen combined with the higher amounts of phosphoric acid. Increasing the quantity of nitrogen induced an abnormal growth of top.

Sugar-beet culture (*Sucr. Indig. et Colon.*, 81 (1913), No. 19, pp. 441-446).—Variety tests in 1912 yielded from 14,800 to 22,500 kg. per hectare (6.6 to 10 tons per acre) of roots, with a percentage of sugar ranging from 13.65 to 16.27 per cent. A classification was made according to the attitude of the foliage of the growing beets, i. e., erect, spreading, and intermediate, and 3 sizes of roots, large, small, and medium in each class, were analyzed, but no definite relation was discovered between density, purity or sugar content, and size or foliage.

Correlation between the size of seed ball and the germinative ability of beet seeds, H. PLAHN-APPIANI (*Bl. Zuckerrübenbau*, 20 (1913), No. 2, pp. 20-24, fig. 1).—The results given in this article show the germinative ability of beet seeds to decrease as the weight of the seed ball increases, and to increase with the size of the seed ball when based on count.

Some figures relative to beet seeds (*Sta. Agron. Aisne Bul.*, 1912, pp. 44-47).—Data are given showing the number of seed per kilogram of balls, the weight of 100 balls, and the 4 sizes into which the seeds may be divided. The large seeds gave the better results in producing strong vigorous plants.

Sugar-cane experiments in the Leeward Islands, F. WATTS ET AL. (*Imp. Dept. Agr. West Indies, Sugar-Cane Expts. Leeward Isl.*, 1911-12, pts. 1-2, pp. 111).—This is a detailed report of the results of variety tests with plant and ratoon canes and manurial experiments with cane, in continuation of work already noted (*E. S. R.*, 26, p. 837).

The study of sugar-cane varieties with a view to their classification, G. N. SAHASRABUDDHE (*West Indian Bul.*, 12 (1912), No. 1, pp. 378-387, pl. 1).—This paper reviews previous attempts toward botanical description and classifica-

tion of the varieties of sugar cane, and discusses as points for consideration the leaves, stem, internodes, nodes, eye-bud, and inflorescence.

The fuller's teasel, W. DALLIMORE (*Roy. Bot. Gard. Kew, Bul. Misc. Inform.*, 1912, No. 7, pp. 345-350; *abs. in Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 2, pp. 237, 238).—This article describes the cultivation of teasel in England, the United States, and France.

The production of bright tobacco by the flue and air curing processes, H. W. TAYLOR (*Agr. Jour. Union So. Africa*, 5 (1913), No. 6, pp. 880-909, *figs. 12*).—This article gives the history of the air and flue curing processes, with the advantages of each, and descriptions and diagrams of various kinds of drying barns. Varieties of tobacco to grow for each of these methods of curing are mentioned, and descriptions given of the best methods to employ in the production of bright tobacco, including selection and care of seed plants, seed beds, soil and its preparation and management, transplanting, cultivation, topping, suckering, ripening, harvesting, curing, preparation for market, and insect pests.

Trifolium parviflorum and *T. angulatum*, B. SZABTORISZ (*Kísérlet. Közlem.*, 15 (1912), No. 5, pp. 782-789).—From an exhaustive study of these annuals the author notes that they grow luxuriantly in wet weather conditions, that they improve the value of pastures where the soil contains an abundance of sodium, but otherwise are failures, that many of the seeds are hard-coated and do not germinate the first season, and that they seem to be immune to the attacks of the dodder.

Environmental influences on the physical and chemical characteristics of wheat, J. A. LECLERC and P. A. YODER (*U. S. Dept. Agr., Jour. Agr. Research*, 1 (1914), No. 4, pp. 275-291).—This article continues reports on work begun in 1909 (*E. S. R.*, 22, p. 730; 29, p. 835), in which soils from California, Kansas and Maryland were transported and compared with local soils of each of the 3 States and wheat grown on them.

It is noted "that in about 80 per cent of the samples investigated the weight of 1,000 grains of seed grown on different soils in any one locality was sufficiently uniform to permit the conclusion that climate and not soil is the chief factor affecting the size of the grain." It was found that the weight of a bushel of wheat ran more or less parallel with the weight of 1,000 kernels. In "classifying the grains of each sample into those which were wholly dark or flinty and those which appeared to be light brown or mealy, a remarkable uniformity is found in the groups arranged by locality in which they grew and a dissimilarity in groups arranged by the source of soil." From data obtained "it seems justifiable to conclude that climate is the principal factor influencing the protein content of wheat, and that soils, when used as in this experiment, have little or no influence."

It is noted that the fiber content of the kernel varied more widely than either the fat or gliadin, and that a greater influence was exerted by seasonal or climatic changes than by differences in soils. "The average ash content of all crops grown on each of the 3 soils, irrespective of the locality, showed but slight variation, being 2.13, 2.08, and 2.16 per cent for California, Kansas, and Maryland soils, respectively." In most cases the amounts of potash and of phosphoric acid rose and fell in the same proportion as the ash.

"Although the relationship or interdependence between the physical properties and chemical constituents does not show in these results as markedly as might be expected, such relationships may be distinctly traced in some of the constituents. Thus, as has often been pointed out by others, a distinct correlation exists between the protein content and the physical appearance or between

the protein content and the weight of 1,000 grains, high protein being more or less parallel with flintiness and with lightness of grains."

In studying the effect of disturbing the soil due to removal, transportation, and replacing, it was shown that "the crops from the plats which had been taken up in 3-in. layers and replaced had approximately the same physical and chemical characteristics throughout as the crops from the corresponding plats, which had not been thus disturbed. On the other hand, it is shown that the climatic factors collectively have a strong determining influence, especially upon the crude protein content, the ash content, and the percentage of phosphoric acid in the ash. The results from this experiment thus harmonize with the findings previously published, namely, that environment rather than what has been usually termed heredity is the major factor in determining the physical and chemical characteristics of the wheat crop. They indicate, further, that it is the climatic environment which exercises the primary influence of the environmental factors."

Breeding work with alternating wheat, M. SERVIT (*Monatsh. Landw.*, 6 (1913), No. 6, pp. 173-183, figs. 7).—Negative results are reported with experiments in which efforts were made during 1910 and 1911 to increase the yield of a variety of wheat which may be seeded alternately as a spring and a winter wheat.

On the stability of a dwarf variety of wheat, P. DE VILMORIN (*Jour. Genetics*, 3 (1913), No. 1, pp. 67-76, pl. 1, figs. 8).—In this paper the author gives results of selections, covering a series of years, of dwarf plants from a variety of common wheat. The dwarf character seemed to be dominant to the large character, but gave a ratio of 2:1 instead of 3:1, as might have been expected.

[Wheat production] (*Ann. Rpt. Ill. Farmers' Inst.*, 17 (1912), pp. 277-299).—Experiences in wheat growing, in which the yields reached 46.8 bu. per acre, are here related by E. W. Johnson, A. A. Hinkley, and others. An address on How Breeding Will Help Wheat Production in Illinois, by L. H. Smith, is included.

The employment of sulphuric acid for the destruction of weeds in the wheat field, E. RABATÉ (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 33 (1912), Nos. 44, pp. 568-572; 45, pp. 591-595; 46, pp. 629-636, figs. 11).—After trials of sulphate of copper, sulphate of iron, and sulphuric acid in varying strengths, the author concludes that sulphuric acid in 6, 8, or 10 per cent solutions (the degree of strength depending upon local conditions) is the most satisfactory spray to use. The solution was applied at the rate of 1,000 liters per hectare (107 gal. per acre) and killed most of the annual weeds, but it did not perceptibly retard the growth of the wheat although the lower leaves were killed. This solution had the advantage of being effective in 3 or 4 hours, while the salt solution required 3 or 4 days. The sulphuric acid solution also had a fertilizing effect on the soil.

A complete description of the method of application and the apparatus used is also given.

HORTICULTURE.

Biennial report division of horticulture (Oregon Sta. Bul. 115, pp. 50, figs. 7).—This bulletin comprises the two following substation reports:

First biennial report, substation, Umatilla Experiment Farm, Hermiston, Oregon, R. W. Allen (pp. 5-46).—The author discusses the methods of procedure since 1909 in preparing the land at the substation for experimental purposes; outlines the experimental work in soil fertility, cover crops, irrigation, cultural and variety tests of fruits, vegetables, and ornamentals; and

gives the results thus far secured. See also a previous note (E. S. R., 29, p. 540).

Report of the Southern Oregon Experiment Station, F. C. Reimer (pp. 46-50).—A similar but briefer report of the new substation at Talent, Oreg.

[Report of the] division of horticulture, H. T. EDWARDS (*Philippine Agr. Rev. [English Ed.]*, 6 (1913), No. 12, pp. 619-629, pls. 4).—This is a brief progress report on work with fruits, vegetables, and other plants at the Singalong and Lamao experiment stations and on work at the Ilagan tobacco station including also notes on the seed and plant distribution, the banana and tropical fruit collection, apiculture, locust extermination, and miscellaneous entomological work.

Spraying, W. J. ALLEN (*Dept. Agr. N. S. Wales, Farmers' Bul.* 72, 1913, pp. 23).—Directions are given for the preparation and use of various spray mixtures, including a spraying calendar for the treatment of insect pests and plant diseases.

Florida trucking for beginners, L. L. BATEMAN (*DeLand, Fla., 1913, pp. 205, figs. 5*).—A popular treatise in which, in addition to cultural details, information is given relative to the development and management of a truck farm in Florida.

The forcing and blanching of dasheen shoots, R. A. YOUNG (*U. S. Dept. Agr., Bur. Plant Indus., Forcing and Blanching of Dasheen Shoots*, pp. 6, figs. 5).—In continuation of previous investigations (E. S. R., 29, p. 336) the author here describes a method of forcing and blanching dasheen shoots to be used as a fresh vegetable during the winter. The treatment here discussed is based on greenhouse experiments conducted cooperatively by the Bureau of Plant Industry and J. H. Kellogg at Battle Creek, Mich. In addition to cultural details instructions are given for handling and keeping the shoots, together with suggestions relative to their culinary uses.

Tomato culture, S. F. ANDERSON (*New Zeal. Dept. Agr., Indus., and Com. Bul.* 33, n. ser., 1913, pp. 24, figs. 9).—A popular treatise on the forcing house and the field culture of tomatoes.

The present status of the fruit industry of the Dominion of Canada, W. T. MACOUN (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 12, pp. 1812-1819).—A popular account, in which the fruit industry of Canada is briefly considered with reference to its history, kinds of fruit grown, fruit districts, export statistics, varieties and breeding, cultivation and marketing, and government aid to fruit growers.

Progress and results in fruit growing in Germany, A. LOEGUS (*Internat. Inst. Agr. [Rome], Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 4, pp. 506-513).—A summarized account of the activities of German pomologists and fruit growers in the improvement and extension of commercial fruit growing in Germany.

Blooming periods and yields of fruit in relation to minimum temperatures, A. B. BALLANTYNE (*Utah Sta. Bul.* 128, pp. 245-261, figs. 10).—In this bulletin the author shows in a series of tables and charts the blooming periods and yields of different kinds and varieties of fruits, together with the minimum temperatures at the Southern Utah Experiment Farm for the years 1903 to 1910, inclusive.

The data appear to show definitely that this area is totally unfitted for the production of nuts or stone fruits, such as peaches, plums, and cherries. Frosts occurring at the blooming time were severe enough to destroy practically all of the crops of the first 3 years after the trees began blooming and to reduce the crops severely in subsequent years. Frosts of from 5 to 9° were less damaging

when the buds were moist than those of a similar or slightly greater severity when the buds were dry.

A preliminary report on the pollination of the sweet cherry, V. R. GARDNER (*Oregon Sta. Bul. 116, pp. 40, pls. 12*).—In the attempt to secure pure bred seeds of a number of varieties of the sweet cherry for use in further breeding investigations, considerable data were secured in 1911 and in 1912 which tended to show that some varieties of the sweet cherry are practically self-sterile and that certain varieties are much better pollenizers than others for the Napoleon, Lambert, and Bing varieties. The work was considerably extended in 1913 to determine, if possible, whether certain sweet cherry varieties are intersterile as well as self-sterile. The results secured during the 3 seasons are here presented in tabular form and discussed.

All of the varieties tested were found to be self-sterile. On the other hand, the pollen of each of the varieties tested is capable of producing a set of fruit on the variety or varieties with which it is interfertile. Certain of these varieties, such as Bing, Lambert, and Napoleon were intersterile, hence mixed plantings of such varieties can not be expected to set fruit unless the trees are within the range of influence of some other variety or varieties that are interfertile with them. Black Republican, Black Tartarian, and Waterhouse seem to be the most efficient pollenizers for the intersterile group, although other varieties were more or less effective. Certain of the seedling trees found in and about cherry orchards were efficient pollenizers for the Bing, Lambert, and Napoleon. At least some members of the Duke group of cherries and of the sour cherry group are capable of pollinating some of the Bigarreaus. Intersterility of sweet cherry varieties is apparently not correlated with their closeness of relationship.

The author's observations during the 3 seasons lead him to conclude that abnormal cherries may be developed on self-sterile, intersterile, and interfertile varieties alike if aphids happen to attack the leaves and pedicels in the flower cluster. The fruit that is developed is very much undersized though the stone is nearly normal. The question is raised as to whether or not this development of fruit as a result of aphid stimulation is akin to the development of parthenocarpic fruit.

Commercial peach growing in Michigan, F. M. BARDEN and H. J. EUSTACE (*Michigan Sta. Special Bul. 63, pp. 30, figs. 12*).—A practical treatise on the establishment, care, and management of a commercial peach orchard, including a financial statement covering a period of 6 years of a 15-acre peach orchard.

Systems of planting for orchards, N. O. BOOTH (*Oklahoma Sta. Circ. 20, pp. 8, figs. 7*).—In this circular the square, hexagonal or triangular, and quincunx systems of planting orchards are illustrated and described.

Fruit packages in the Middle West, L. G. HERRON (*Oklahoma Sta. Circ. 21, pp. 3-27, figs. 28*).—In this circular the author points out the relative merits of various styles of fruit packages in actual use.

Preserving fruits for exhibition purposes, N. O. BOOTH (*Oklahoma Sta. Circ. 22, pp. 3*).—This circular contains instructions and formulas for preserving various fruits and vegetables for exhibition purposes.

The rational manuring of fruit trees and grapevines, R. DUMONT (*La Fumure raisonnée des Arbres fruitiers et de la Vigne. Paris [1913], pp. 191, figs. 11*).—A practical treatise similar to the above on the manuring of fruit trees and grapes grown both under glass and in the open.

The cultivation of the vine under glass, S. F. ANDERSON (*New Zeal. Dept. Agr., Indus., and Com. Bul. 40, n. ser., 1913, pp. 35, figs. 20*).—A popular treatise on the culture of greenhouse grapes, including directions for preparing the soil and constructing a vine house.

Commercial strawberry culture, S. B. SHAW (*Bul. N. C. Dept. Agr.*, 34 (1913), No. 8, pp. 24, figs. 14).—A practical treatise on strawberry culture in North Carolina, based on investigations conducted on the Pender Test Farm and throughout the commercial strawberry sections. A chapter on strawberry insects, by F. Sherman, Jr., is included.

Manurial experiments on cacao, 1912-13, J. DE VERTEUIL (*Dept. Agr. Trinidad and Tobago Bul.*, 12 (1913), No. 76, pp. 205-216).—This report contains yield data for the year ended August 31, 1913, for manurial experiments which are being conducted on a number of private cacao plantations. Data were also secured on the natural yield of plats on 8 cacao estates situated in different parts of the island with the view of determining what factor or factors other than manures affect the yield of cacao trees. The results, as here tabulated, indicate that the yield of a group of cacao trees forming a plat is susceptible to very large variations and that the yield tendencies on any particular plat should be well known before manurial experiments are undertaken.

California citrus culture, A. J. COOK (*Sacramento, Cal.: State Com. Hort.*, 1913, pp. 121, figs. 68).—A practical treatise on the establishment, culture, and management of citrus groves in California, including information relative to various citrus diseases and insect pests and their control, methods of marketing, etc.

An extensive bibliography on citrus fruits is appended.

Date cultivation in the Punjab, D. MILNE (*Lahore, Brit. India: Govt.*, 1913, pp. III+20, pls. 7).—A practical treatise based upon the author's observations in Egypt and India and on the literature of date culture in various countries.

The palms of British India and Ceylon, indigenous and introduced, E. BLATTER (*Jour. Bombay Nat. Hist. Soc.*, 20 (1910), Nos. 1, pp. 33-64; 2, pp. 347-360; 20 (1911), Nos. 3, pp. 675-705; 4, pp. 981-995, 21 (1911), No. 1, pp. 66-86; 21 (1912), Nos. 2, pp. 343-391; 3, pp. 912-968; 22 (1913), No. 1, pp. 67-86, pls. 50, figs. 31).—This comprises a series of descriptive articles on the native and introduced palms of British India and Ceylon. In addition to a detailed botanical description each species is considered with reference to its bibliography, nomenclature, distribution, and habitat, together with the cultivation and uses in the case of economic species. An extensive bibliography on palms is included in the introductory chapter. The text is fully illustrated.

The selection of the tea plant, C. BERNARD and P. VAN LEERSUM (*Dept. Landb., Nijv. en Handel [Dutch East Indies], Meded. Proefstat. Thee*, 1913, Nos. 21, pp. 30, pls. 12; 26, pp. 15, pls. 4).—In continuation of previous tests relative to the germination of tea seed selected according to its specific gravity in water and in sugar solutions (E. S. R., 24, p. 41), the results to date are here reported of a test of various types of Assam tea, including imported types and those grown in Java from Assam seed.

Observations of the young plants have shown that seed which sinks in water produces more vigorous plants than seed which floats in water, and that the most vigorous plants are produced from seed which sinks in a 25 per cent sugar solution. Favorable results have been secured against troubles in the seed bed by disinfecting the seed with corrosive sublimate solution. The selected plants have been budded on thrifty stocks for further observation.

Green manuring, G. D. HOPE and A. C. TUNSTALL (*Indian Tea Assoc., Sci. Dept. Quart. Jour.*, 1912, No. 4, pp. 99-103, pl. 1; 1913, Nos. 1, pp. 22-25; 2, pp. 43-47, pl. 1; 3, pp. 73-78).—A series of articles comprising a general discussion of the subject of green manuring, including notes and data on the use of various cover crops for manuring tea.

Ornamental hibiscus in Hawaii, E. V. WILCOX and V. S. HOLT (*Hawaii Sta. Bul.* 29, pp. 60, pls. 16).—This bulletin contains detailed descriptions of a large number of native, introduced, and hybridized ornamental forms of hibiscus that have been under observation at the Hawaii Station. A number of these forms are shown in color and the methods of culture, directions for hybridizing, and some of the hybrids are described at length. Brief reference is also made to the insects and diseases of hibiscus.

The rational manuring of flowers and ornamental plants, R. DUMONT (*La Fumure raisonnée des Fleurs et des Plantes ornementales*. Paris, [1913], pp. 152, figs. 21).—A practical treatise on the manuring of flowers and ornamental plants, based largely on experimental results secured by the author and other investigators. The succeeding chapters discuss the nutrition of plants; horticultural soils; horticultural fertilizers; soils, composts, and amendments used in horticulture; and the manuring of flowers and ornamental plants growing in the open, in pots, and under glass.

Garden trees and shrubs, W. P. WRIGHT (*London*, 1913, pp. 337, pls. 84, figs. 11).—In part 1 of this popular work the author discusses the beauty and value of shrubs and trees for various situations. Part 2 deals with the arrangement, propagation, planting, culture, and care of trees and shrubs. Part 3 forms a guide to the selection of trees and shrubs for various effects and purposes. Part 4 comprises a descriptive account of the principal trees and shrubs. The work is fully illustrated with colored plates and half-tone engravings.

Shrubs of Florida, J. K. SMALL (*New York*, 1913, pp. X+140).—A handbook of the native and naturalized shrubs of Florida, including a key to the orders considered.

The useful plants of New Caledonia, E. HECKEL (*Les Plantes Utiles de Nouvelle-Calédonie*. Marseille and Paris, 1913, pp. 93, pls. 41, figs. 7).—This comprises descriptive notes with illustrations of a number of economic plants observed by the author in New Caledonia.

FORESTRY.

The American woods, illustrated by actual specimens with full text, XIII, R. B. HOUGH (*Lowville*, N. Y., 1913, pp. VI+49, pls. 13, wood sections 25).—The present volume of this series (E. S. R., 26, p. 442) contains sets of wood sections of 25 tropical species growing in southern Florida and the adjacent keys. A systematic study of the species represented accompanies the wood sections, together with a series of photographic pictures of characteristic barks and foliage.

Specific gravity and weight of the most important American woods, A. GASKILL (*Forestry Quart.*, 11 (1913), No. 4, pp. 527-530).—The author here presents a table showing the specific gravity and weight of the most important American woods. In order to reduce or harmonize the contradictions that appear in published figures on the subject comparisons were made between all available data, and specimens of every species were carefully analyzed and compared. Densities were then more or less arbitrarily assigned which recognize the inherent characters of the individual species.

Relation of precipitation to tree growth, M. N. STEWART (*Mo. Weather Rev.*, 41 (1913), No. 9, p. 1287).—The author made a series of measurements of an oak stump in order to discover, if possible, whether the precipitation of previous years directly affected the ring widths and, if so, to determine the comparative amounts of rainfall during periods for which no records exist. The comparisons were confined to the precipitation during the growing season.

The author concludes that June and July precipitation seems to have most effect upon the width of oak rings. Decrease of width more than 0.5 mm. below normal would appear to be quite certain indication of a subnormal summer rainfall. Although an increase in width did not necessarily appear to be an effect of extra abundant rainfall, this holds in 62 per cent of the cases.

It is pointed out that, generally speaking, the examination of this tree does not show an accurate ratio between ring width and the rainfall since other unknown factors, such as temperature, insect pests, height of surrounding timber, etc., have a disturbing influence.

The present status of cultural experiments with foreign timber species in the state forests of Saxony, F. W. NEGER (*Naturw. Ztschr. Forst u. Landw.*, 12 (1914), No. 1, pp. 1-11).—Notes are given on the present status and condition of a number of foreign timber species which have been under observation in the state forests of Saxony during the past 10 years.

The forest flora of New South Wales, J. H. MAIDEN (*Sydney, N. S. Wales: Govt.*, vol. 5, 1910, pts. 1, pp. 19; 2, pp. 21-52; 1911, pts. 3, pp. 53-68; 4, pp. 69-89; 5, pp. 91-103; 6, pp. 105-124; 1912, pts. 7, pp. 125-145; 8, pp. 147-158; 9, pp. 159-177; 10, pp. 179-191, pls. 67; *Index*, 1913, pp. XI).—This is the fifth of a series of volumes on the forest flora of New South Wales, the first of which was issued in 1903. In the present volume 38 species are described, each species being considered with reference to its botanical characteristics, common and scientific nomenclature, size, habitat, economic products, and propagation.

Atlas of the tree species of Java, S. H. KOORDERS and T. VALETON (*Atlas der Baumarten von Java. Leiden, Netherlands, 1913, vol. 1, Nos. 1, pp. VII, pls. 50; 2, pls. 50; 3, pls. 50, 4, pp. 14, pls. 50*).—This atlas, which is issued in 4 parts, constitutes an appendix to the author's series of contributions on the tree species of Java (*E. S. R.*, 25, p. 142). The illustrations for each species in the atlas consist of a flowering twig, floral and leaf parts, and in most cases a sketch showing the general appearance of the tree. No descriptions accompany the illustrations, but reference is made to the descriptive text in the authors' previous publications.

Some Douglas fir plantations.—III, Llandinam plantation, Montgomeryshire, F. STORY (*Jour. Bd. Agr. [London]*, 20 (1913), No. 8, pp. 690-696, figs. 2).—In continuation of previous observations on Douglas fir plantations (*E. S. R.*, 30, p. 46) growth and yield tables are given for a 28-year-old stand growing in mixture with larch in Montgomeryshire, North Wales.

Lupine straw as a means of improving the growth of fir stands on drifting sand, E. HESSELINK (*Cultura*, 25 (1913), No. 304, pp. 455-466, pl. 1, figs. 5).—In the experimental tests here reported lupine straw was used as a ground covering and compared with the sparse native vegetation which was simply mowed and left on the ground. Stands of fir in which the lupine straw was used were found to make a much greater root and top development.

Forest management of loblolly pine in Delaware, Maryland, and Virginia, W. D. STERRETT (*U. S. Dept. Agr. Bul. 11, pp. 59, pls. 5, fig. 1*).—In order to show the financial possibilities in growing loblolly pine in Maryland, Delaware, and Virginia the author here presents and discusses data dealing with the rate of growth and yield; past, present, and prospective lumber prices; cost of lumber production; stumpage values; expectation values for different initial investments, rotations, types of soil, and distances from market; cost of various silvicultural operations; and size, volume, and yield tables. The best systems of management are described, and the loblolly pine is also considered with reference to its nomenclature, botanical and silvical characteristics, utilization, and characteristics of the wood.

Eucalypts, R. DE NOTER (*Les Eucalyptus*. Paris, 1912, pp. 119, figs. 37).—A compilation of information on the eucalypts dealing especially with their culture, exploitation, vegetative and industrial qualities, and medicinal properties. The subject matter is prepared with special reference to the extension of eucalyptus culture in the French colonies.

Recent contributions to the knowledge of the genus *Hevea*, J. HUBER (*Bol. Mus. Goeldi Hist. Nat. e Ethnog.*, 7 (1910), pp. 199–281, pl. 1).—A series of papers, in the first of which the author discusses the systematic and geographical distribution of the genus *Hevea*. In the second paper consideration is given to a number of species of *Hevea* found along the Rio Iça-Putumayo. In the third paper the distribution of *Hevea* species in Para is discussed and in the fourth the author reports an investigation of the variability of characters in the genus *Hevea* with reference to the possibilities of a selection method. Special consideration is given to the variations in seed characters.

The forest problem in Chili, F. ALBERT (*Bol. Bosques, Pesca i Caza*, 1 (1913), No. 10, pp. 649–719, pl. 1, figs. 81).—A survey of forest conditions in Chili with recommendations for the conservation and extension of the forest resources of that country.

Some aspects of European forestry, A. B. RECKNAGEL (*Forestry Quart.*, 11 (1913), No. 4, pp. 470–498).—In continuation of previous papers on this subject (*E. S. R.*, 29, p. 842), the author here discusses methods of natural and artificial regeneration in Austria.

Annual report of the director of forestry of the Philippine Islands for the fiscal year ended June 30, 1913, G. P. AHERN (*Ann. Rpt. Dir. Forestry P. I.*, 1913, pp. 65, pls. 6).—A progress report on the administrative, investigational, and reconnaissance work in the Philippines for the year ended June 30, 1913.

The appendix contains statistics relative to the certification of public lands; amounts of important timbers, by species, cut; revenues and expenditures; timber licenses in force; utilization of forest products; and exports and imports.

Annual progress report upon state forest administration in South Australia for the year 1912–13, W. GILL (*Ann. Rpt. State Forest Admin. So. Aust.*, 1912–13, pp. 12, pls. 7).—A statistical report for the year ended June 30, 1913, relative to the extent of forest reserves, planting and other forest operations, distribution of trees, revenues, expenditures, etc.

The conservation of wood, R. BARBIER (*Rev. Vit.*, 40 (1913), Nos. 1037, pp. 516–520; 1039, pp. 574–580).—This paper, which was presented at the International Congress of Forestry, Paris, 1913, comprises an exposition on the natural and artificial processes of preserving wood.

The transportation of wood in the colonial forests, A. JOLYET (*Le Transport des Bois dans les Forêts Coloniales*. Paris, 1912, 2. ed., rev., pp. 60, figs. 16).—A descriptive account of methods of exploiting and transporting logs in the French colonies.

Forest fire protection by the States as described by representative men at the Weeks law forest fire conference, edited by J. G. PETERS (*U. S. Dept. Agr., Forest Serv., Forest Fire Protection by States*, pp. 85, pls. 2, fig. 1).—This comprises the papers, addresses, and discussions at the conference of federal and state officials and other representatives of various forest interests, held at Washington, January 9–10, 1913, to discuss informally cooperation in the protection from fire of the forested watersheds of navigable streams, as provided for under section 2 of the Weeks law (*E. S. R.*, 24, p. 498). An appendix contains forms of agreement between the Department and the States and telephone companies with reference to fire protection.

The use of vegetation for reclaiming tidal lands, G. O. CASE (*London, 1913*, pp. 36, figs. 9; *Engineering* [London], 96 (1913), Nos. 2486, pp. 264, 265; 2489, pp. 344-347, 349, figs. 9).—An account of the utilization of various plants and trees in the reclamation of tidal lands in different countries.

DISEASES OF PLANTS.

Report of phytopathological observations, 1911 and 1912, E. MARCHAL (*Min. Agr. et Trav. Pub. [Belgium], Off. Rural Raps. et Communs.*, 1913, No. 7, pp. 71-85, figs. 2; *Ann. Sta. Agron. Etat. Gembloux*, 2 (1913), pp. 367-383, figs. 2).—Brief notes are given of observations relating to *Urocystis occulta*, *Puccinia glumarum*, and *P. graminis* on grain plants; *Septoria petroselinii apii* on celery; a threatening extension of *Exobasidium azaleæ* near Ghent; a rust of currant, possibly due to a form of *P. caricis*; a pear tree rust not named, also *S. piricola* on pears; leaf scald of grape; *Ustilago hordei* on winter barley; *Phytophthora infestans*, *Macrosporium solani*, and *Chrysophlyctis endobiotica* on potatoes (the last named being treated at some length); a lettuce fungus, possibly a form of *Æcidium lactucæ sativæ*; an oïdium on currants; *Lophodermium brachysporum* on pine needles; and a threatening leaf spot disease of *Aspidistra*, provisionally accredited to *Pyrenochaeta bergervini*.

Report on plant diseases, R. SCHANDER ET AL. (*Mitt. Kaiser Wilhelms Inst. Landw. Bromberg*, 6 (1912), No. 1, pp. 42-58).—The author presents notes by himself and associates regarding investigations carried on in plant chemistry, morphology, physiology, and pathology, the last named relating to *Fusarium nivale* on winter wheat, loose smut of barley and wheat, leaf spot of wheat associated with nematode attack, the physiology of *Phoma betæ*, and several potato fungi.

Report on plant protection of the experiment station for agricultural chemistry at Görz, 1912, J. BOLLE (*Ztschr. Landw. Versuchsw. Österr.*, 16 (1913), No. 4, pp. 299-303).—It is stated that the wet summer and fall of the previous year resulted in an observed greater prevalence of fungus diseases. Spraying the under side of grape leaves for *Peronospora* did not seem to give any decided advantage over the ordinary method. Forhin, a mixture giving off ammonia fumes, said to have been recommended from Germany for *Peronospora*, spotted the leaves without checking the fungus. *Exoascus deformans*, appearing very early on peach leaves, was treated with a spray containing 1 per cent copper sulphate, 0.5 quicklime, and 0.5 ammonium chlorid. The leaves were killed, but the new leaves which appeared were free from peach curl late in summer. The treatment is to be modified and extended to other stone fruits.

A brief report is given also on insect injuries observed.

Root nematodes, A. VUILLET (*Rev. Phytopath.*, 1 (1913), No. 2, pp. 17-19, figs. 3; *abs. in Riv. Patol. Veg.*, 6 (1913), No. 6, pp. 187-189).—A brief discussion of the characteristics, distribution, biology, and economic importance of *Heterodera radiculicola* in relation to crops is given. The author recommends, as protection therefrom, the employment of 240 gm. carbon bisulphid per square meter of soil, repeated after an interval of 15 days.

Notes on a cereal disease, V. W. PASTOR (*Memoria é Instrucciones para combatir la plaga de los cereales de Olot, conocida con el nombre de "Boixat."* Gerona, Spain: Cons. Prov. Fomento, 1913, pp. 7).—A nematode attacking wheat and rye, but not barley, in the vicinity of Olot in northeast Spain, is thought to be *Tylenchus devastatrix*. This is said to cause loss also by attacking onions, beans, and hyacinths in this region.

Appearance and treatment of stinking smut, O. APPEL (*Mitt. Deut. Landw. Gesell.*, 28 (1913), *Beilage No. 16*, pp. 1-3, figs. 3).—Noting unusually severe outbreaks of stinking smut during the current year, the author recommends the treatment of seed grain with 0.25 per cent formaldehyde for from 10 to 15 minutes. A second treatment recommended is steeping in 0.5 per cent copper sulphate for from 12 to 16 hours, followed by 1 per cent lime solution for $\frac{1}{2}$ hour.

Tests of the hot water treatment of barley and spring wheat at the Pentkowa Experiment Farm, 1912, K. BIELER (*Illus. Landw. Ztg.*, 33 (1913), No. 58, pp. 533-535, fig. 1).—In the treatment of barley and spring wheat seed with water at 25 to 30° C. for 4 hours and for 5 to 10 minutes at 50 to 52° it was found that barley seed was lowered in germinability when the temperature exceeded 51°, while the wheat underwent a temperature of 52° without injury.

Antecedents and history of a disease of garlic, V. W. PASTOR (*Antecedentes é Historia de la enfermedad de los Ajos, denominada "Boirat" en Bañolas. Gerona, Spain: Cons. Prov. Fomento, 1913, pp. 15, pl. 1*).—A disease of garlic is described which has been known for some years around Bañolas in northeastern Spain and which has recently been the cause of considerable damage. It is said to be noted in connection with the bulb mite (*Rhizoglyphus echinopus*) with which was associated also a bacillus, possibly *B. omnivorus* or *B. cepivorus* reported on bulbs by Delacroix (*E. S. R.*, 18, p. 745).

On the effect of spraying potatoes with soda Bordeaux mixture, J. PORTER (*Herefordshire County Council Farmers' Bul. 1, 1910, pp. 4*).—Instead of the lime Bordeaux, a mixture was used consisting of 12 lbs. sulphate of copper, 15 lbs. pure washing soda, and 100 gal. of water. The spray was effective in preventing potato disease, especially when both the upper and lower surfaces of the leaves were sprayed. The yield was increased 1 ton 12 $\frac{3}{4}$ cwt. per acre.

Treatment for nematodes, L. BRUNEHANT (*Bl. Zuckerrübenbau, 20 (1913), No. 19, pp. 289-291*).—The author reports improvement in the yield of ground infested with beet nematodes by applying stable and chemical manures and growing the crops in rotation. The order of rotation was beets, wheat, oats, and alfalfa followed by succession of wheat, beets, wheat, oats, and rye or potatoes, with superphosphate or liquid and other manures.

Selection and treatment of cane seed, J. R. JOHNSTON (*Porto Rico Sugar Producers' Sta. Bul. 6 (English Ed.), pp. 29*).—A study was made of the relative value of different parts of the sugar cane stalk for planting, germination and disease resistance being considered.

The author concludes that, other things being equal, top seed give better results than body seed. Only healthy cane should be used in planting and special efforts should be made to avoid seed from cane affected by the pineapple disease, red rot, rind disease, top rot, and root rot.

Experiments with a number of fungicides showed that when the seed was planted under good conditions there was no perceptible improvement in germination, but when disinfectants were applied to infected seed or good seed planted under poor conditions there was a considerable increase in the percentage of germination. The author states that seed cane exposed to the air becomes infected with a number of fungi. Where a large amount of pineapple disease is present all seed should be treated with Bordeaux mixture. Also seed that is not to be planted immediately or that that is to be shipped should be similarly treated. While the presence of diseased leaf sheaths on seed cane would not affect germination or subsequent growth, the author claims that they should be removed when mealy bugs are abundant or when the seed is to be treated.

A bibliography is appended.

Black rot of tobacco, R. RAPAICS (*Magyar Dohányynjsag*, 30 (1913), No. 4, pp. 2-4; abs. in *Internat. Inst. Agr. [Rome]*, Mo. Bul. Agr. Intel. and Plant Diseases, 4 (1913), No. 4, p. 659).—A destructive disease attacking tobacco during its fermentation and decomposing the leaves, said to be unknown in Europe until recently, is reported from Hungary. The trouble is stated to be due to the activity of *Sterigmatocystis (Aspergillus) nigra*. No remedy has as yet been announced.

The mosaic disease of tobacco, H. A. ALLARD (*U. S. Dept. Agr. Bul.* 40, pp. 33, pls. 7).—The results of a preliminary series of investigations on the cause of mosaic disease of tobacco and other solanaceous plants are given.

This disease the author found was communicable to a large number of solanaceous plants but not to plants of other families. It is said to be quite similar to the mosaic disease of pokeweed. The mosaic virus permeates all parts of the plant but does not infect the embryos of the seed; therefore such seed will produce healthy plants. Once initiated, the disease becomes a progressive, incurable malady. It was found possible to infect plants with the sap of mosaic plants which had been passed through a filter.

Certain species of aphids are considered active disseminators of the mosaic disease, and observations made in the field show that they may sometimes be responsible for the occurrence of the disease in the seed bed and its subsequent spread in the field. In these experiments cutting back, repotting, or otherwise subjecting plants to unfavorable conditions did not prove sufficient to produce infectious mosaic symptoms. Physiological disturbances in the plants are not believed to be an adequate cause of this disease, and the author believes that organisms are its primary cause, although none have yet been isolated.

A new disease of cucumbers, ALTHEIMER (*Prakt. Bl. Pflanzenbau u. Schutz*, n. ser., 11 (1913), No. 9, pp. 109-112).—The author reports the receipt from Schwaben of cucumber leaves spotted by a fungus which is said to be identical with *Corynespora maei (C. melonis)*, already destructive in England and Holland. Its possibilities for harm are said to be great, especially where phosphoric acid is lacking. It is said to be carried with the seed, and it is recommended that the latter be treated with copper sulphate of 2 per cent strength before being used or shipped.

Tomato rot, L. PAVARINO (*Riv. Patol. Veg.*, 6 (1913), No. 6, pp. 161-163).—The author states that tomato rot, noted by Groenewege (*E. S. R.*, 29, p. 246) as due to an organism described under the name *Phytobacter lycopersicum* n. sp., is identical with that already described by himself (*E. S. R.*, 25, p. 148) and named *Bacterium briosii* n. sp.

Experiments on the control of the cedar rust of apples, H. S. REED, J. S. COOLEY, and C. H. CRABILL (*Virginia Sta. Bul.* 203, pp. 28, figs. 11).—After describing the cause of the rust of apples, symptoms, and effect, the authors give an account of spraying experiments carried on during 1911, 1912, and 1913.

Lime sulphur, iron lime sulphur, copper lime sulphur, atomic sulphur, Bordeaux mixture, iron Bordeaux mixture, and mercuric bichlorid were tested, and data are presented indicating the amount of reduction in disease, as shown by leaf infections. The experiments indicate that certain spray materials have great value in controlling cedar rust in the orchard, copper lime sulphur, a new fungicide, being very efficient in this respect. Ordinary lime sulphur and Bordeaux mixture were also found to give good results.

In the course of the experiments it was found that the maximum infection takes place only during the very early stages of leaf development. If the weather conditions are unsuitable for the development of sporidia, the infection will not appear on the earlier leaves.

In a laboratory experiment on the effect of the different spray materials on the germination of sporidia, all of the fungicides were found to reduce germination materially.

While spraying was found efficient in controlling apple rust, it is thought that it would be cheaper and more effectual to remove cedar trees from the vicinity of orchards.

Evaporation of water by normal or by chlorotic leaves of pear, J. CROCHETELLE (*Jour. Agr. Prat.*, n. ser., 26 (1913), No. 41, pp. 469, 470).—The author reports an average hourly evaporation per square centimeter from the surface of green and of chlorotic pear leaves of 5.72 and 1.76 mg., respectively. This is considered to show a freer circulation of water in the green leaves.

On a disease of greengage trees caused by *Dermatella prunastri*, W. J. DOWSON (*New Phytol.*, 12 (1913), No. 6, pp. 207-216, figs. 3).—An investigation was begun on a disease of greengage plum trees which was carried little beyond the identification of the fungus and determining some facts regarding its life history when the work was terminated, but the author presents the results as far as they had been conducted, giving an account of the isolation of the fungus, field observations, inoculation experiments, etc.

It is stated that the greengages were chiefly attacked, but that the fungus has also been found on other varieties. Diseased branches and twigs die back and the dead branches show the presence of the fruiting bodies of the fungus. Inoculation experiments were begun which indicate that infection takes place through wounds. The mycelia arising from both conidia and ascospores were grown on nutrient agar and sterilized pieces of greengage wood, and pycnidia were produced in about three weeks. The mycelium was found present in all the tissues of the host, particularly in the wood and pith. Its advance into a branch is preceded by gumming in the woody elements. Inoculation of healthy trees with the mycelium of *D. prunastri* is said to have led to infection.

Silver-leaf disease, F. T. BROOKS (*Jour. Bd. Agr. [London]*, 20 (1913), No. 8, pp. 682-690, pls. 2).—A summary account is given of the author's investigations and observations on the silver-leaf disease in continuation of the report previously noted (*E. S. R.*, 29, p. 847). The present article deals principally with the part played by *Stereum purpureum* in causing the disease.

The anthracnose of the mango in Florida, S. M. McMURRAN (*U. S. Dept. Agr. Bul.* 52, pp. 15, pls. 4, figs. 4).—The results of a study of the mango anthracnose, due to *Colletotrichum glaucosporioides*, in Florida together with some spraying experiments for its control are given.

The author states that the production of mangoes is seriously interfered with in certain seasons by this fungus, which attacks not only the flower clusters, fruits, and leaves, but also the young shoots. The blossom blight form of the disease is said to be the most serious, and the amount of damage is dependent on weather conditions, moist, showery weather being ideal for its rapid development.

So far as the spraying experiments in Florida are concerned, spraying proved of little value in preventing the blighting of the blossoms during rainy seasons at blooming time, though it served to keep the panicles and fruits free from infection. The author believes that seasons will never be so dry but that spraying will have to be resorted to in order to keep fruits free from disease after they have set.

Court-noué, L. RAVAZ (*Vie Agr. et Rurale*, 2 (1913), No. 27, pp. 10-15).—The author discusses briefly the present distribution of court-noué under its various names, its characters, its alleged causes, its conditions of development (including susceptible or resistant varieties), and suggested preventive measures,

including employment of resistant stocks named, close in preference to wide planting, and replanting with stocks from roncet free localities.

Court-noué associated with acarirose in Swiss vineyards, H. FAES (*Vie Agr. et Rurale*, 2 (1913), No. 27, pp. 14-17, fig. 1).—Claiming that court-noué of grapevines, associated with general or physiological conditions in France, as held by Ravaz (E. S. R., 29, p. 551), and in Italy, according to Pantanelli (E. S. R., 28, p. 851), is due in Switzerland and Austria to the presence of an acarid (*Phyllocoptes vitis*), previously described in connection with vine injury (E. S. R., 24, p. 168), the author suggests the application in February or March of alkaline polysulphid in 3 per cent solution.

Studies on grape downy mildew, G. DE ISTVÁNFFI and G. PÁLINKÁS (*Ann. Inst. Cent. Ampélog. Roy. Hongrois*, 4 (1913), pp. 125, pls. 9, figs. 2; *abs. in Gard. Chron.*, 3. ser., 54 (1913), No. 1046, p. 402).—This is a fuller account of studies pursued for several years and in part already reported (E. S. R., 29, p. 350). It deals in considerable detail with the relations between plant and parasite, discussing also some points still under investigation.

It is stated that the germ tube enters by the stoma, forming beneath a secondary spore, which throws out branching filaments. The oil spots are centers of infection and are due to the presence of mycelium in and around the stomata. In the leaf the hyphæ appear more slender in dry weather. The incubation period depends upon temperature and weather. It may be shortened by hot, rainy weather, with absence of the oil spots. The form and size of the latter also show a relation to the age of the leaves. At 6 to 8° C. the conidia are said to retain their vitality for from 3 to 8 weeks. Infection occurs more readily on the lower surface of the leaf. The receptivity to infection bears some relation to substomatal vapor tension, to cell turgor, and to chemical composition of the cell sap. Rain, fog, and dew favor infection.

A classified bibliography is given.

Studies on grape downy mildew, G. DE ISTVÁNFFI and G. PÁLINKÁS (*Rev. Vit.*, 40 (1913), Nos. 1036, pp. 481-484; 1037, pp. 509-513; 1038, pp. 540-543).—This is a more detailed discussion than that previously given (E. S. R., 29, p. 350), and deals with the development of *Plasmopara viticola* in the different organs and the utilization of the incubation period for preventive treatment.

Recent researches on grape mildew (*Plasmopara viticola*), G. DE ISTVÁNFFI and PÁLINKÁS (*Internat. Inst. Agr. [Rome]*, *Mo. Bul. Agr. Intel. and Plant Diseases*, 4 (1913), No. 10, pp. 1651-1655).—This gives briefly the substance of the communications above noted from other sources.

Red scald of grapes, II, H. MÜLLER-THURGAU (*Centbl. Bakt. [etc.]*, 2. Abt., 38 (1913), No. 21-25, pp. 586-621, pl. 1).—Reporting further studies (E. S. R., 28, p. 55) on *Pseudopeziza tracheiphila*, the cause of red scald of grape leaves, the author states that the fungus can live through the winter in dead leaves and develop therefrom in the spring. It probably does not invade the shoots, but the hyphæ enter the leaf from either side during periods of moderate dryness and follow the vascular bundles. The author recommends as preventive or remedial measures the destruction of fallen or diseased leaves, improvement in physical conditions and fertility of the soil, the planting of resistant varieties, and spraying with Bordeaux mixture.

Some diseases of pecans, F. V. RAND (*U. S. Dept. Agr., Jour. Agr. Research*, 1 (1914), No. 4, pp. 303-338, pls. 5, figs. 8).—A number of the more common diseases of the pecan are described. Among these, nursery blight, due to *Phyllosticta caryæ*, is said to be a serious disease of young trees but seldom found in producing orchards. Brown leaf spot, caused by *Cercospora fusca*, is widely

distributed, but, except during wet seasons, causes very little injury. Pecan anthracnose, due to *Glomerella cingulata*, is extensively distributed, but has not proved a very serious pest in any locality. Kernel spot, due to *Coniothyrium caryogenum* n. sp., is said to be rare, and the investigations on this disease thus far have been confined to laboratory and greenhouse work. A technical description of the fungus is given. Crown gall, caused by *Bacterium tumefaciens*, is reported as having been found on pecans in northern Florida and southern Mississippi.

Observations on rust of mallows, L. BLARINGHEM (*Bul. Soc. Bot. France*, 59 (1912), No. 8, pp. 765-773; *abs. in Mycol. Centbl.*, 3 (1913), No. 3, p. 125).—The author concludes from his observations that the development of *Puccinia malvacearum* on *Althaea rosea* and on *A. officinalis* is favored by dryness and light, the latter species being the more sensitive to the action of the parasite.

The influence exerted by rusts on respiration and chlorophyll assimilation by leaves, G. NICOLAS (*Rev. Gén. Bot.*, 25 (1913), No. 297, pp. 385-395).—A comparison of assimilation and respiration in rusted and in rust free leaves of olive, ash, and several other trees is held to show that rusts hinder both these processes.

A twig blight of *Quercus prinus* and related species, DELLA E. INGRAM (*U. S. Dept. Agr., Jour. Agr. Research*, 1 (1914), No. 4, pp. 339-346, pl. 1, figs. 7).—The author describes a disease of the chestnut oak (*Q. prinus*) which, while primarily a disease of this species, is said to be occasionally found on the American chestnut and the white oak.

The fungus causing the disease is referred to *Diplodia longispora*. It is said that large trees are not killed outright, but that they may eventually die as a result of the weakened condition caused by losing the young branches. The saplings are often killed outright.

Infection takes place through wounds in the bark, and the fungus has not been found present in leaf tissues.

A preliminary account of this disease, where it is attributed to *Dothiorella quercina*, has been noted elsewhere (*E. S. R.*, 27, p. 654).

Withertip of fir, T. LAGERBERG (*Skogsvårdsför. Tidskr., Fackaf.*, 1913, No. 3, pp. 173-208, figs. 19; *abs. in Riv. Patol. Veg.*, 6 (1913), No. 7, pp. 213, 214).—A withertip fungus on fir, causing extensive loss in Sweden, has been studied with the result that the organism is declared to be a form of that known as *Brunchorstia destruens*, the name *Crumenula abietina* n. sp. being applied by the author.

An undescribed species of *Gymnosporangium* from Japan, W. H. LONG (*U. S. Dept. Agr., Jour. Agr. Research*, 1 (1914), No. 4, pp. 353-356).—In a previous publication by Clinton (*E. S. R.*, 29, p. 547) attention was called to the introduction of *G. japonicum* on *Juniperus chinensis*. A study of some of the material has led the author to the conclusion that the rust on the woody stems is this species, but that occurring on the leaves or young twigs differs materially, and this is described as *G. chinensis* n. sp.

A leaf disease of Para rubber, C. K. BANCROFT (*Jour. Bd. Agr. Brit. Guiana*, 7 (1913), No. 1, pp. 37, 38).—A new but as yet not very abundant fungus is reported as parasitic on leaves of *Hevea* on a farm in British Guiana. Spots form, increase in size, and finally die and drop out, leaving a hole in the leaf. The fungus was declared at the Kew gardens to be new and was named by Masee *Passalora hevea*. A trial of lime-sulphur mixture is recommended, also the destruction of affected leaves before transplanting.

ECONOMIC ZOOLOGY—ENTOMOLOGY.

Guide to the study of animal ecology, C. C. ADAMS (*New York, 1913, pp. XII+183, pls. 7*).—In the preparation of this work, which indicates briefly some of the general bearings of the subject and method of approach, the author has kept in mind the needs of the beginner in ecology.

The subject is dealt with under the headings of aim, content, and point of view; the value and method of ecological surveys; field study, the collection, preservation, and determination of specimens; references to scientific technique; references to important sources of information on the life histories and habits of insects and allied invertebrates; the laws of environmental change; the laws of orderly sequence or metabolism, growth, development, physiological conditions, and behavior; and the continuous process of adjustment between the environment and the animal, with special reference to other organisms.

Bibliographies are given for the several subjects and author and subject indexes are included.

The birds of Connecticut, J. H. SAGE and L. B. BISHOP (*Conn. State Geol. and Nat. Hist. Survey Bul. 20, 1913, pp. 370*).—In the preparation of the first part of this work (pp. 15-257), which consists (1) of a catalogue of the birds of Connecticut with records of their occurrence within the State, (2) a statistical summary, (3) a list of observers referred to by initials or by surnames, and (4) a bibliography of 58 pages of the important books and articles, the authors were assisted by W. P. Bliss. The second part (pp. 259-360), which is by L. B. Bishop, deals with economic ornithology. An index is included.

The economic importance of the Hungarian partridge (*Perdix perdix*) (*Aquila, 19 (1912), No. 1-4, pp. 166-209*).—The first part of this paper (pp. 166-201), which is by L. Thaisz, relates to the vegetable food, and the second part (pp. 202-209), by E. Csiki, to the insect food of the Hungarian or gray partridge, a species which has been introduced into the United States, as previously noted (*E. S. R., 23, p. 154*).

Examination of contents of stomachs and crops of Australian birds, J. B. CLELAND (*Emu, 11 (1911), No. 2, pp. 79-95*).—Previously noted from another source (*E. S. R., 29, p. 756*).

Fifth annual report of the Quebec Society for the Protection of Plants from Insects and Fungus Diseases, 1912-13 (*Ann. Rpt. Quebec Soc. Protec. Plants [etc.], 5 (1912-13), pp. 95, figs. 46*).—Among the more important entomological papers in this report are the following: Parasitic Insects in the Control of Injurious Forms, by W. Lochhead (pp. 12-23); The Sawflies of the Province of Quebec, by T. W. Fyles (pp. 27-31); The Rôle Played by Bees in Fertilization of Flowers, by F. W. L. Sladen (pp. 39, 40); Some Insects which Attack the Roots of Vegetables, by A. Gibson (pp. 41, 42); Some Insect Enemies of Shade Trees, by J. M. Swaine (pp. 43-58); An Old Enemy of the Potato [*Meloidæ*], by J. C. Chapais (pp. 72-75); and Concerning Cutworms, Wireworms, and White Grubs, by W. Lochhead (pp. 85-94).

Injurious insects in Brazil, G. BONDAR (*Bol. Agr. [Sao Paulo], 14. ser., 1913, No. 1, pp. 28-42, figs. 16*).—This is a general account of important insect enemies of the common fig (*Ficus carica*) and of a related wild form in Brazil. Special mention is made of the injury caused by the buprestid borer *Colobogaster quadridentata*; the cerambycid borers *Taniotes scalaris* and *Trachyderes thoracicus*; the curculionid *Heilipus bonelli*, which bores in the trunks; the pyralid *Azochis gripusalis*, which bores in the limbs; the sphingid *Pachylia ficus*; and the coccid *Morganella maskelli*.

A further contribution to the knowledge of the enemies of the olive, G. DEL GUERCIO (*Redia, 9 (1913), No. 1, pp. 59-75; abs. in Rev. Appl. Ent., 1 (1913),*

Ser. A, No. 10, pp. 390, 391).—The notes here presented relate to the olive lecanium (*Lecanium oleæ*), the leopard moth (*Zeuzera pyrina*), the olive tineid (*Prays oleællus*), the olive psylla (*Euphyllura olivina*), and the scolytid *Hylesinus oleiperda*.

The natural enemies of vineyard pests, J. FEYTAUD (*Rev. Vit.*, 39 (1913), Nos. 994, pp. 5-9, pl. 1; 995, pp. 36-40, figs. 2; 996, pp. 76-81, figs. 2; 997, pp. 97-101, figs. 3; 998, pp. 137-141, figs. 2).—The first portion (pp. 5-9, 36-40) of this paper deals with the more important insect predators; the second (pp. 76-81, 97-101, 137-141) with insect parasites.

Insect enemies of the elm in France, F. PICARD (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 34 (1913), No. 49, pp. 712-719, pl. 1).—In this account the author deals with the elm leaf beetle (*Galerucella luteola*), the elm scolytid (*Scolytus destructor*), the small scolytid of the elm (*S. pygmaeus*), the elm anthaxia (*Anthaxia manca*), the copper buprestid (*Pæcilonota decipiens*), the elm saperda (*Saperda punctata*), the elm necydale (*Necydalis ulmi*), and the goat moth (*Cossus ligniperda*).

The sanitary pathological importance of insects and related arthropods, E. A. GÖLDI (*Die sanitärisch-pathologische Bedeutung der Insekten und verwandten Gliedertiere, namentlich als Krankheits-Erreger und Krankheits-Überträger. Berlin, 1913, pp. 155, figs. 178*).—The first part of this work relates to stinging, biting, and irritating insects and arthropods (pp. 9-28); the second part to bloodsucking insects and other arthropods (pp. 28-122); and the third to insects and other arthropods as disease transmitters (pp. 122-151). A subject index is appended.

Powdered arsenate of lead as an insecticide, W. E. HINDS (*Jour. Econ. Ent.*, 6 (1913), No. 6, pp. 477-479).—The author states that he has yet to hear of a single instance in which dry powdered arsenate of lead caused the formation of a sore upon either man or beast when engaged in its application, or of a single case of internal poisoning resulting from its extensive use. "At the present time we know of no reason why anyone should hesitate to use powdered arsenate of lead in preference to Paris green or any other arsenical poison now commonly obtainable upon the market."

Catalogue of palearctic Hemiptera (Heteroptera, Homoptera-Auchenorrhyncha, and Psylloideæ), B. OSHANIN (*Katalog der paläarktischen Hemipteren. Berlin, 1912, pp. XVI+187*).—This catalogue lists more than 5,369 species. It includes indexes (1) to the species and varieties, and (2) to the subgenera, genera, and higher groups.

On fungi parasitic on scale insects found in Formosa, K. MIYABE and K. SAWADA (*Jour. Col. Agr. Tohoku Imp. Univ.*, 5 (1913), No. 3, pp. 73-90, pls. 2; *abs. in Agr. News [Barbados]*, 12 (1913), No. 299, p. 334).—This paper deals with 7 species of fungi found to be parasitic on scale insects in Formosa, namely, *Aschersonia aleyrodes* and *Ophionectria tetraspora* n. sp., parasitic on *Parlatoria zizyphi* infesting *Citrus nobilis*; *A. marginata*, parasitic on *Coccus longulus* and *P. zizyphi* infesting *Citrus nobilis* and *Psidium guajava*; *A. suzukii* n. sp., parasitic on *Coccus longulus* infesting the living leaves and branches of *Citrus nobilis* and *Fagara nitida*; *Sphærostilbe coccophila*, parasitic on *P. zizyphi*, *Mytilaspis gloverii*, and *Aspidiotus ficus* infesting *Citrus nobilis*, *Ficus wightiana*, and *Thea chinensis*; *Microcera fujikuroi* n. sp. on *Aspidiotus ficus* infesting *Citrus nobilis*, and commonly found throughout the island of Formosa, often associated with *Microcera coccophila*; and *O. coccicola*, parasitic on *P. zizyphi*, *Aspidiotus ficus*, *Mytilaspis gloverii*, and *M. citricola* infesting *Citrus nobilis*.

It is stated that some species are not recorded in the present paper because of the imperfect condition of the specimens and that these will be treated in a future paper, together with fungi parasitic on scale insects found in other parts of Japan. A list of the papers referred to is appended.

On the development of the eggs of *Bombyx* (*Sericaria*) *mori* the first month after deposition, M. RIZZI (*Redia*, 8 (1912), No. 2, pp. 323-359, pls. 4).—The report of an embryological study of the silkworm, with a bibliography of 17 titles.

Control of army worm and cotton caterpillar, E. L. WORSHAM (*Ga. Bd. Ent. Bul.* 36, 1912, pp. 8, figs. 5).—A popular account.

The wilt disease of gipsy moth caterpillars, R. W. GLASER and J. W. CHAPMAN (*Jour. Econ. Ent.*, 6 (1913), No. 6, pp. 479-488).—The authors' experiments and observations are summarized as follows:

"The presence of polyhedral bodies in the blood corpuscles may be useful in diagnosing the health of nun moth caterpillars, but this test can not be used for gipsy moth caterpillars with any degree of certainty. The virus of wilt disease is filterable with difficulty. Such a filtrate is free from bacteria and polyhedral bodies. Caterpillars dead from the infection with the filtered virus are flaccid, completely disintegrated, and full of polyhedral bodies. Usually the complete absence of bacteria immediately after death is very striking as cultures and smears show. Minute dancing granules were observed in the diseased tissue cells with very high powers. These same granules were also noticed in the Berkefeld filtrate. There is no evidence that polyhedral bodies are stages of the filterable virus. A large number of caterpillars used in the experiments died, due to disturbances in their normal physiological activities. There is no evidence that the wind is an important factor in distributing the disease. Infection naturally takes place through the mouth by means of the food. Apparent immunity is a striking phenomenon."

A bibliography of 17 titles is appended. See also a previous note (E. S. R., 27, p. 660).

Notes on a chestnut tree insect, A. G. RUGGLES (*Science*, n. ser., 38 (1913), No. 989, p. 852).—These notes relate to an undetermined lepidopteran which is referred to as the "bast miner" because of the habit of the larvæ of burrowing in the bark of the chestnut tree, particularly in smooth-barked trees. The larvæ hibernate in the burrows in either the second or third instar. The burrow, which extends longitudinally, is not very extensive, the longest not being more than 6 in.; it can not be detected externally while the borer is within the bark, but after the emergence of the larvæ the bark swells over the burrow, often cracking and making a conspicuous wound. The larvæ leave the trees during the first part of June through minute exit holes and drop to the soil, in which they spin a seed-pod-like cocoon. Under insectary conditions the adult insect emerges during August.

Since the number of exit holes made by these larvæ is enormous in any given area of chestnut forest and as these holes are made just at the time of the year when the blight spores are very abundant and conditions generally are favorable to their development, it is thought that this insect has an important bearing upon the spread of *Endothia parasitica*.

A list of mosquitoes hitherto reported from New Orleans, C. WELLMAN and H. D. KING (*Amer. Jour. Trop. Diseases and Prev. Med.*, 1 (1913), No. 4, pp. 267-280).—Twenty species representing 9 genera are recorded in this paper, which is said to be preliminary to a systematic mosquito survey of the city and environs of New Orleans, planned for the spring and summer of 1914. References to the medical and zoological literature which has been searched

with the object of recording previous work on New Orleans mosquitoes are appended.

Life history of syrphid fly predaceous on frog hopper nymphs, P. L. GUPPY (*Dept. Agr. Trinidad and Tobago Bul.*, 12 (1913), No. 75, pp. 159-161, figs. 3; *Dept. Agr. Trinidad and Tobago Spec. Circ.* 8, 1913, pp. 5, figs. 3).—The syrphid fly here dealt with, the name of which is omitted, is said to be the most important enemy of the frog hopper, and an attempt will be made to breed it on a large scale. It has been found by dissection that the ovaries contain upwards of 350 eggs and that there are 30 egg tubes in each ovary and 6 eggs in each tube. From 30 to 40 nymphs are killed during the life of the maggot, which is from 9 to 10 days' duration, and there is no doubt but that it destroys numbers of very small nymphs wherever these are abundant. The egg was found to require $2\frac{1}{2}$ days for its development, the larva 9 to 10 days, and the pupa 9 days.

Recommendations for dealing with the frog hopper, J. C. KERSHAW (*Dept. Agr. Trinidad and Tobago Spec. Circ.* 9, 1913, pp. 10).—This circular includes a brief discussion of syrphus fly [*Salpingogaster nigra*] above noted; manner of dealing with trash; use of trap lights, a summary of recommendations; and miscellaneous notes.

A new botfly from reindeer, F. KNAB (*Proc. Biol. Soc. Wash.*, 26 (1913), pp. 155, 156).—Under the name *Oedemagena terranovæ* the author describes a second species of botfly which infests the reindeer (*Rangifer terranovæ*) peculiar to Newfoundland. This is the second species of the genus of which *O. tarandi*, the first, was described in 1736 from Lapland. *O. tarandi* has frequently been reported from northern localities of the Old World and a number of times from the boreal regions of North America, including Alaska.

The geographical distribution of the stable fly, Stomoxys calcitrans, C. T. BRUES (*Jour. Econ. Ent.*, 6 (1913), No. 6, pp. 459-477).—"The stable fly (*S. calcitrans*) is one of the most widely distributed insects, rivaling the house fly in this respect. It occurs commonly in parts of every zoological region and practically throughout most of them. It is probably native to the palearctic region from whence it has followed man in his migrations to all parts of the world. In the United States it was common in the vicinity of Philadelphia as early as 1776. It is not equally abundant everywhere that it occurs, but is much more common in temperate regions such as the United States and Argentina. In the Tropics it occurs very generally, but almost always in lesser numbers than in cooler climates."

The domestic fly (Muscina stabulans), an enemy of man and his household, and, in the larval stage, of the larvæ of the house fly, I. A. PORTCHINSKY (*Trudy Bûro Ent. [St. Petersburg.]*, 10 (1913), No. 1, pp. 39, figs. 32; *abs. in Rev. Appl. Ent.*, 1 (1913), Ser. B, No. 6, pp. 108-110).—It is stated that the second stage larvæ of this species attack the larvæ of the house fly and very soon exterminate all that happen to be living nearby. The larvæ also destroy the larvæ of *Hydrotæa dentipes*, which species is also carnivorous and destroys the larvæ of the house fly. The larvæ of *Polyetes albolineata*, however, are always victorious over those of *M. stabulans*, even when the latter are larger. Another species of the genus, *M. pabulorum*, is an important enemy of the larvæ of *Sciara militaris*. The author has never observed the larvæ of *M. stabulans* eating each other, as is the case with some other larvæ (*P. albolineata*). In his opinion the harm done by *M. stabulans* in destroying the larvæ of a useful fly such as *H. dentipes* outweighs its utility as a destroyer of the larvæ of the house fly.

"The author gives a detailed description of *M. stabulans* and of its habits, and points out at length the differences between the eggs of this fly and those of *Musca domestica*, as well as of two other flies commonly found in human dwellings, *Calliphora erythrocephala* and *Fannia canicularis*, all of the eggs being figured. *M. stabulans* may lay as many as 160 small eggs, spreading them singly or in lines over the whole surface of the object on which they are laid, which makes them more difficult to recognize than those of other flies. . . . The author confirms the statement of Bouché that this fly is able to go through all its transformations in about a month, thus being able to produce several generations during the summer."

Narcissus flies, R. S. MACDOUGALL (*Jour. Bd. Agr. [London]*, 20 (1913), No. 7, pp. 594-599, figs. 2).—This paper relates to the large narcissus bulb fly (*Merodon equestris*) and *Eumerus strigatus*.

Notes on the bean fly (*Agromyza phaseoli*), E. JARVIS (*Queensland Agr. Jour.*, 30 (1913), No. 3, pp. 192-195, figs. 2).—This troublesome pest (E. S. R., 29, p. 657), is said to be on the increase and slowly but surely extending its range both in Queensland and New South Wales.

Biological studies of the auchmeromyids, E. ROUBAUD (*Bul. Soc. Path. Exot.*, 6 (1913), No. 2, pp. 128-130).—The adults of these flies are said to be coprophagous and the larvæ exclusively hematophagous.

Studies of the auchmeromyids; calliphorine flies with bloodsucking larvæ occurring in tropical Africa, E. ROUBAUD (*Bul. Sci. France et Belg.*, 47 (1913), No. 2, pp. 105-202, pls. 2, figs. 32; abs. in *Rev. Appl. Ent.*, 1 (1913), Ser. B, No. 10, pp. 172-175).—This paper deals at length with (1) the classification (pp. 109-128) and (2) the biology and organization of Diptera of the genera *Chæromyia* and *Auchmeromyia*.

A bibliography of 30 titles is appended.

Studies of the Diptera with internal entomophagous larvæ, II, J. PANTEL (*Cellule*, 29 (1913), No. 1, pp. 289, pls. 7, figs. 26).—The first section (pp. 8-114) of the second part of this work (E. S. R., 23, p. 562) relates to the egg envelopes (vitelline membrane and chorion) and their dependents; the second section (pp. 115-252) to indirect injury from parasitism.

The indirect injury due to parasites is taken up under the headings of (1) indirect injury not affecting the reproductive function; (2) indirect injury of the reproductive function, indirect parasitic castration; (3) is parasitic castration a phenomenon "sui generis"?—nonparasitic alterations of the female gonad in various insects.

The literature relating to these subjects is reviewed in connection with a bibliography of 8 pages.

A catalogue of Coleoptera (*Coleopterorum Catalogus. Berlin*, 1912, pts. 48, pp. 92; 49, pp. 135-290; 50, pp. 291-450; 51, pp. 103; 52, pp. 108; 53, pp. 278; 54, pp. 29; 55, pp. 74).—In continuation of this work (E. S. R., 28, p. 256) part 48, by M. Pic catalogues the Anobiidæ; parts 49 and 50, by K. W. von Dalla Torre, the subfamily Melolonthinæ III and IV of the Scarabæidæ; part 51, by H. Clavareau, the subfamilies Sagrinæ, Donaciinæ, Orsodacninæ, and Criocerinæ of the Chrysomelidæ; part 52, by A. Lameere, the subfamily Prioninæ of the Cerambycidæ; part 53, by H. Clavareau, the subfamilies Megascelinæ, Megalopodinæ, Clytrinæ, Cryptocephalinæ, Chlamydinæ, and Lamprosominæ of the Chrysomelidæ; part 54, by E. Csiki, the Rhipiphoridæ; and part 55, by M. Pic, the Bruchidæ.

The grape flea beetle in France, F. PICARD (*Prog. Agr. et Vit. (Ed. l'Est-Centre)*, 34 (1913), No. 5, pp. 139-145, pl. 1).—A brief account of *Haltica ampelophaga*, including its natural enemies and remedial measures.

The natural enemies mentioned include the predatory bug *Zicrona carulea*, a braconid parasite of the larva (*Perilitus brevicollis*), a tachinid parasite of the adult (*Degeeria funebris*) which some years parasitizes 85 per cent of the flea beetles and in an indirect manner prevents their reproduction, and the fungus *Beauveria* (*Sporotrichum*) *globuliferum*.

Notes on Podabrus pruinosus, H. F. WILSON (*Jour. Econ. Ent.*, 6 (1913), No. 6, pp. 457-459, fig. 1).—This beetle is said to have been abundant in the Willamette Valley in Oregon during the past two years and one of the most important agencies in the control of all forms of plant lice, the rosy apple aphid (*Aphis sorbi*), the black cherry aphid (*Myzus cerasi*), and the vetch aphid (*Macrosiphum pisi*) being the principal species held in check. The beetle crushes the aphids with its mandibles and extracts the juices.

The rhinoceros beetle (*Oryctes rhinoceros*) in Samoa, R. W. DOANE (*Jour. Econ. Ent.*, 6 (1913), No. 6, pp. 437-442, pls. 2).—This is a report of studies made by the author in Samoa during May, June, and July, 1913.

New potato weevils from Andean South America, W. D. PIERCE (*U. S. Dept. Agr., Jour. Agr. Research*, 1 (1914), No. 4, pp. 347-352, pls. 3, figs. 3).—A number of shipments of South American potatoes during the year 1913 for experimental propagation by this Department have been found infested with live weevils. As a result the Federal Horticultural Board has excluded South American potatoes from the United States. The author has made a study and here presents information upon the weevils concerned with a view to assisting the inspectors in their work.

The three species thus far found are said to be very different in appearance. An account of one of the weevils, namely, *Rhigopsidius tucumanus*, received in potatoes from Peru, Bolivia, and Chili, has previously been noted (E. S. R., 29, p. 761). The two additional weevils each represent a new genus and species and are here described as *Premnotrypes solani* and *Trypopremnon latithorax*. *P. solani* was found alive in a potato sent from the mountain districts of Peru, the adult weevil having been found just beneath the skin of the potato in a small cell which evidently served as a feeding cell for the larva. The material received indicates that the larva does not bore extensively in the potato. Several specimens of *T. latithorax* were found in cells in potatoes received from Cuzco, Peru, the species developing in a manner closely resembling that of *P. solani*. *R. tucumanus* appears to be more widely distributed and the source of greater injury than either of the other two species.

The pathogenicity of Nosema apis to insects other than hive bees, H. B. FANTHAM and ANNIE PORTER (*Ann. Trop. Med. and Par.*, 7 (1913), No. 4, pp. 569-579).—"N. apis has been proved pathogenic to Hymenoptera other than bees. It can multiply in the food canals of humble bees, mason bees, and wasps, and can bring about the deaths of the hosts. Contamination of plants with infected excrement occurs in the neighborhood of badly infected hives. Such contaminated food is pathogenic to the larvæ of cabbage white butterflies, cinnabar moths, and gooseberry moths, in which *N. apis* produces destruction of the tissue of the food canal in the same way as in bees. Both imagines and larvæ of these insects became infected with microsporidiosis when supplied with food contaminated with *Nosema* spores.

"*Calliphora erythrocephala*, the blow fly, becomes infected naturally by ingesting *Nosema* spores contained in the sweet excrement of bees. This infection has been repeated experimentally. Crane flies may also become infected.

"A member of the Hippoboscidae, *Melophagus ovinus*, has been infected successfully with *N. apis*, which is pathogenic to the sheep ked. It is suggested

that research be made by competent observers among the Glossinæ for microsporidian parasites allied to the Nosema of bees, and, possibly, equally pathogenic to the tsetse flies that may harbor them."

The evolution and larval forms of *Diachasma crawfordi* n. sp., D. KEILIN and C. PICADO (*Bul. Sci. France and Belg.*, 47 (1913), No. 2, pp. 203-214, pl. 1, figs. 4).—The braconid parasite of the fruit fly *Anastrepha striata* here described as new was discovered by the authors while conducting studies in Paris of material brought from Orosi, Costa Rica, where this fly highly infests the guava (*Psidium*). It is thought that this may be the same as the parasite collected by Crawford (E. S. R., 25, p. 56) in Mexico, and which, apparently unknown to the present authors, was described by Viereck (E. S. R., 26, p. 352) as *D. crawfordi*. Some 10 per cent of fruit fly larvæ were found to be parasitized. It is stated that *Biosteres brasiliensis* and *B. areolatus* have been reared from pupæ of *A. fraterculus* from Brazil.

The brown-tail and gipsy moths and parasites, E. E. PHILBROOK (*Bul. [Maine] Dept. Agr.*, 12 (1913), No. 4, pp. 18, pls. 11).—A detailed discussion of these pests with an account on Parasite Introduction into Maine, by A. M. G. Soule (pp. 10-18).

Hereditary infection, with special reference to its occurrence in *Hyalomma ægyptium* infected with *Crithidia hyalommmæ*, W. R. O'FARRELL (*Ann. Trop. Med. and Par.*, 7 (1913), No. 4, pp. 545-562, pls. 3).—"C. *hyalommmæ* is a flagellate parasite occurring in the hæmocœlic fluid, salivary glands, ovary, oviducts and ova of *H. ægyptium*, the common cattle tick of the Anglo-Egyptian Sudan. The parasite has 4 periods in its life cycle, a preflagellate stage passed chiefly in the hæmocœlic fluid, a flagellate stage in the hæmocœlic fluid and in the ovary and oviducts, a postflagellate stage in the hæmocœlic fluid, and a post-flagellate or ovarian stage in the ovary and oviducts, ovarian cells, and ova. . .

"Multiplication of *C. hyalommmæ* by longitudinal division takes place in all its stages. Infection of *H. ægyptium* by *C. hyalommmæ* in the adult is purely a hereditary infection. The flagellate is a strictly parasitic flagellate of the tick, and is nonpathogenic to the tick host."

FOODS—HUMAN NUTRITION.

The chemical milling and baking value of Utah wheats, R. STEWART and C. T. HIRST (*Utah Sta. Bul.* 125, pp. 115-150).—Additional data are reported regarding the studies of Utah wheats which have been carried on (E. S. R., 25, p. 263). The necessity for standardizing western grains is insisted upon and the details given of studies of 1907-1909 spring wheats and winter wheats grown under dry-farming conditions and of irrigated wheats.

The authors summarize the data regarding the yield and composition of the milling products, the composition of the flours, and the bread making qualities of these wheats as follows:

"The weight per 100 kernels of the irrigated wheat is greater than that of either the spring or winter dry-farming wheat. The yield of flour, bran, and shorts shows nothing characteristic. . .

"Nothing characteristic is shown with respect to the moisture content except that it is low in every case. The protein content of irrigated wheat is lower than that of either the spring or winter dry-farm wheat. The spring wheat contains the highest protein content. The bran and shorts produced from the irrigated wheat have a lower protein content than that produced from dry-farm wheat. . .

"The flour produced from the winter dry-farm wheat has a slightly lower moisture content than the flour produced from the other kinds of wheat. The

protein content of the flour produced from the wheat receiving the greatest amount of irrigation water is 3.11 per cent lower than that produced from spring dry-farm wheat and 2.01 per cent lower than that produced from dry-farm winter wheat. In case of the irrigated varieties of wheat, as the amount of water applied decreases the protein content increases. The protein content of the flour produced from wheat which received no irrigation water is 1 per cent greater than that produced from wheat receiving an application of 25 in., notwithstanding the fact that the seed wheat in both cases was the same and the nonirrigated wheat was grown on land which had been irrigated in previous years. The moist-and-dry gluten content of the flour produced from the irrigated wheat is considerably lower than that produced from either spring or winter dry-farm wheat. . . .

"Nothing characteristic of the several kinds of wheat is shown with respect to the volume of water added or retained. The ratio of protein to volume of water added is narrower in case of the dry-farm grains. The volume of loaf made from dry-farm flour is slightly greater than that produced from irrigated flour. The ratio of protein to volume of loaf is narrower in the dry-farm flour than in the irrigated flour.

"The investigations extending over a period of 8 years clearly demonstrate the fact that the dry-farm grains in Utah are characterized by a low moisture content and a high protein content. They also clearly indicate that the protein content of the dry-farm wheats is higher than the protein content of the wheat on irrigated farms."

Studies in carbohydrates—the composition and digestibility of wheat bread and allied foods [and] gelatinization of starches, C. H. LAWALL and SARA S. GRAVES (*Trans. Wagner Free Inst. Sci. Phila.*, 7 (1913), pt. 2, pp. 35-45).—The results are reported of the microscopic examination of 12 starches, raw and cooked below and at the temperature of boiling water, including starches from cereals, potatoes, sweet potatoes, maranta, beans, and peas. In the cooked starches, "It was noticed that the absorption of water begins at the hilum, working toward the edge until the granules burst or collapse."

Similar studies were made of the starch of white bread, commercial rye, graham, and gluten breads, rolls and crackers, pretzels, and matzoth, and of the starch in cooked vegetables, including beans, peas, and lentils, boiled until soft, baked beans, string beans, and canned French peas (*petits pois*). With the vegetables, "in every case the starch granules were found to be entirely gelatinized, either swollen or broken."

Determinations of the gelatinization points of free starches from cereals, potatoes, sweet potatoes, maranta, beans, peas, and lentils were also made. "Noting the gelatinization points of raw and dried potato starch, and the diverse results in the pea and bean experiments, it is evident that the form of the starch and size of the particles have marked influence. It is possible that the time required to heat to the desired point may affect the result. The greatest difficulty, however, lies in determining the point at which the majority of the granules may be called gelatinized. It is not definite within 1 to 3°.

"As a means of distinguishing starches in a mixture the method appears useless, especially with the small granule starches, such as wheat and rye, in which the refraction is at all times very faint."

The authors investigated the composition, including acidity and condition of carbohydrates, in 5 samples of commercial bread, in homemade bread, and in crackers, pretzels, and matzoth.

"The microscopic examination of starch, both raw and after cooking, has shown that in process of bread making it undergoes a marked change which has a direct effect on the composition and value of the bread produced. From 5 to

8 per cent of the insoluble starch is changed to a soluble form, and very many grains are ruptured and rendered more susceptible to the action of solvents, such as the digestive fluids, by combined action of heat and ferments. The 35 to 40 per cent of water prevents the temperature in the interior of the loaf from rising much above 100°, thus accounting for the small amount of soluble starch in comparison with the 10 to 18 per cent in bread crust and 5 to 12 per cent in crackers.

"With the modern process of bread making on the large scale it is evident that differences in methods or in constituents make only a very slight difference in products, and that claims of superiority, other than on the basis of taste, are untenable."

Salt in bread making, O. J. FREED (*Oper. Miller*, 18 (1913), No. 12, pp. 794-797, figs. 9).—The results of experiments are given on the effects of salt, not to exceed 3½ lbs. per barrel of flour (196 lbs.), upon the yield and quality of bread. The author's conclusions in the main were as follows:

With an increase of salt, the color was improved, the texture and grain were greatly benefited, the volume or size was increased, and the crust of the bread was softened. The more salt the longer it takes the dough to rise, and the less salt, the faster the dough rises.

"When all these points are taken into consideration, we are forced to the conclusion that the safest amount of salt for [white] bread . . . is 3 lbs. to a barrel. . . . Any amount above this, say 3½ lbs., will not only work to retard the fermentation, but will also impair the quality. A bread that has no salt, or insufficient salt, is tasteless and insipid. The salt will retard the fermentation only when it is used in excessive amounts."

In the author's opinion, in extremely hot weather ½ lb. more salt is beneficial, while in the winter time it is desirable to decrease the amount ½ lb. and raise the temperature of the dough to 86° F. In working with hard water less salt is needed than when using soft water.

A new method of handling preserved foods and its value for army and navy use, J. R. KATZ (*Umschau*, 17 (1913), No. 47, pp. 975-978).—The use of pulp or paper containers for sterilized foods is described, a method devised by Miss M. Rutten.

Report of Missouri Home Makers' Conference Association, 1913 (*Missouri Bd. Agr. Mo. Bul.*, 11 (1913), No. 3, pp. 130, figs. 41; *Ann. Rpt. Missouri Bd. Agr.*, 45 (1912), pp. 149-275, figs. 41).—The report contains a number of papers presented, including, among others, The Feeding of Children, [with Menus], by Amy L. Daniels; Hot Lunches in Rural School, by Mrs. Fannie Quick; Teaching Cooking in the Fruitville Rural School, by Helen Swift; The Short Course for Women in the University of Missouri, by Louise Stanley; A Lesson in Drafting Patterns, by Nelle Carter; Art and Hand Work in Rural Schools, by Ella V. Dobbs; School Sanitation, by Louise Stanley; How to Make a Garden Serve the Table the Whole Year, by Mrs. S. W. Ravenel; Farm Home Management, by O. R. Johnson; Farm Home Management, by Mrs. J. E. Hall; Salt-rising Bread, by Winona Woodward; and An International Movement for the Betterment of Rural Homes, by Maude M. Griffith.

Household discoveries and Mrs. Curtis's cook book, S. MORSE and ISABEL G. CURTIS (*Petersburg, N. Y.*, 1913, rev. ed., pp. XXII+33-1173, pls. 6, figs. 247).—Data regarding the care of the home and its equipment, insect pests, and other matters of interest to the housekeeper are presented, the material being arranged in encyclopedic form. A large number of recipes and discussions of food problems are included. Material published by the U. S. Department of Agriculture has been freely drawn upon.

Nutrition and diet, EMMA CONLEY (*New York, Cincinnati, and Chicago, 1913*, pp. 208, pls. 8, figs. 11).—This volume, designed as a text-book for secondary schools, deals with the composition of the human body and of foods and their classification, digestion, the balanced meal, planning of meals, and similar topics, and has chapters on the principal groups of foods. In a number of instances the form of statement might be modified with advantage.

The history of dietetics, J. B. NICHOLS (*Pop. Sci. Mo.*, 83 (1913), No. 5, pp. 417-427).—In this summary and digest of data the author has brought together a large amount of information regarding the experimental study of this subject.

Food and labor, J. AIKEN (*Timchri, Brit. Guiana*, 3. ser., 2 (1912), No. 2, pp. 287-291).—Data are presented and discussed regarding the cost of food of laborers in British Guiana.

Concerning the food of agricultural laborers, MRS. MARGARETE KLÜPPER (*Ztschr. Landw. Kammer Schlesien*, 17 (1913), No. 44, pp. 1629-1632).—The need for considering information regarding the preparation of food is pointed out and a number of recipes given for dishes deemed particularly suitable for rural regions.

The enzymic action of fresh foods and condiments, T. TADOKORO (*Jour. Col. Agr. Tohoku Imp. Univ.*, 5 (1913), No. 2, pp. 57-72).—The carefully expressed juice of udo sprouts, yam tubers, cabbage and lettuce leaves, cucumbers, onions, ginger, and horse-radish roots was used in these experiments.

The enzymic action was tested in the following manner: Samples of raw and of cooked juices from each vegetable were allowed to stand with solutions of albumin, peptone, glycocoll, asparagin and urea, starch, amygdalin and salicin, and hydrogen peroxid, and with castor oil emulsion; the usual tests for peptase, tryptase, amylase, lipase, etc., were then applied and the difference in the results obtained from the cooked and uncooked samples was taken as the measurement of the enzymic action from each vegetable. Oxidasis was tested by color reactions.

The author summarizes his results as follows: (1) Only ginger and onion showed any noticeable peptolytic power; (2) tryptic action was more or less apparent in all the juices except those from onion and horse-radish and was strongest in that from cabbage; (3) none of the juices caused the liberation of ammonia from glycocoll or asparagin, but small amounts were split off from urea in the case of udo sprouts, yams, and ginger; (4) more or less diastatic activity was noted in every case except onion, being strongest in ginger and moderate in yams, horse-radish, and cabbage; (5) lipolytic action was observable only in cabbage; (6) glucosidases were found only with yams and cabbage; (7) various oxidases appeared in all samples, being most noticeable in ginger and onion; (8) catalytic activity was shown with all samples, being strongest in ginger and onion.

The author hopes soon to report on the special nature and digestive influence of the materials here considered.

Studies on amylases.—VI, **A comparison of amyloclastic and saccharogenic powers**, H. C. SHERMAN and M. D. SCHLESINGER (*Jour. Amer. Chem. Soc.*, 35 (1913), No. 11, pp. 1784-1790).—A progress report on work previously noted (*E. S. R.*, 24, p. 122) regarding the activity of amylases under different conditions.

Studies on amylases.—VII, **The forms of nitrogen in amylase preparations from the pancreas and from malt, as shown by the Van Slyke method**, H. C. SHERMAN and A. O. GETTLER (*Jour. Amer. Chem. Soc.*, 35 (1913), No. 11, pp. 1790-1794).—A continuation of the above.

The prolin fraction of the hydrolysis products of casein, F. W. FOREMAN (*Biochem. Ztschr.*, 56 (1913), No. 1-2, pp. 1-10).—Amino butyric acid, not

hitherto identified as a product of protein cleavage, was found in the prolin fraction of casein. An acid substance apparently containing the piperidin ring was also isolated and a base presumably derived from it. Other compounds were present with nitrogen in the form of amino groups. Prolin determined by the Van Slyke method contains these bodies.

The utilization of inulin in diet cures, A. GOUDBERG (*Ztschr. Expt. Path. u. Ther.*, 13 (1913), No. 2, pp. 310-325; *abs. in Zentbl. Expt. Med.*, 4 (1913), No. 11, p. 490).—According to the author, inulin is well digested and utilized in the body. It is not a builder of glycogen.

The total volume of gastric juice secreted during digestion, J. WINTER (*Compt. Rend. Acad. Sci. [Paris]*, 157 (1913), No. 3, pp. 234, 235).—A note on the method of calculating this factor.

The influence of the melting point of nonemulsified fats on the rapidity of their passage out of the stomach, A. VON FEJÉR (*Biochem. Ztschr.*, 53 (1913), No. 1-2, pp. 168-178, fig. 1).—The experiments here reported were similar to those previously reported by Tangl and Erdélyi (*E. S. R.*, 26, p. 159) with fat emulsions and were carried on with laboratory animals (white rats and mice) confined in a respiration calorimeter.

The rapidity with which the nonemulsified fats passed out of the stomach was found to bear a direct relation to the melting point and the degree of viscosity of the fat, higher melting points and greater viscosity accompanying more rapid passage. Nonemulsified fat eaten in combination with ordinary food materials passed out of the stomach more slowly than did the fat emulsions. The rate at which the nonfatty portion of the food left the stomach depended upon the character of the food, the less viscous fat hindering the process less than the viscous.

The fat eaten mixed with other food materials was partially separated from the latter soon after reaching the stomach and passed separately into the intestinal tract.

Concerning the fate of single amino acids, of mixtures of such acids, of peptones, and of proteids introduced into the digestive tract, E. ABDERHALDEN and A. E. LAMPÉ (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 81 (1912), No. 5-6, pp. 473-507).—This article discusses the development of the method of Abderhalden and Schmidt for detecting amino acids in a dialyzate from blood serum by means of a color reaction with triketohydrindene hydrate (*E. S. R.*, 26, p. 804), and gives the results of tests made with the blood of dogs to which meat, creptone, and Witte's peptone had been administered.

Although recognizing the limitations of this indirect and quantitative method of determining the amino acid content, the authors believe that their work furnishes direct proof that certain amino acids pass from the gastrointestinal tract into the blood.

The importance of the thyro-parathyroid in the assimilation of carbohydrates, U. LOMBEROSO and C. ARTOM (*Arch. Farmacol. Sper. e Sci. Aff.*, 16 (1913), No. 7, pp. 289-298).—The authors gave concentrated solutions of sucrose and invert sugar to laboratory animals (dogs) from which the thyroid and parathyroids had been removed and noted the effect upon the elimination of sugar through the urine.

The animals, which showed the general characteristic morbid effects of the operation, showed also a considerable increase in the percentage of both sugars appearing unoxidized in the urine, the rapidity in the appearance and the extent of the increase corresponding to those of the other symptoms. When the disturbances were slight, the sucrose was eliminated largely in the form of glucose; when more profound, it appeared in the urine as sucrose.

This suggests that the thyro-parathyroid glands may play a rôle in the production of inverting enzymes similar to that generally assigned to the pancreas in the production of erepsin and lactase. There is no reason to assume, however, that this influence of the thyroid is as direct and immediate as that of the pancreas. The contrary is implied by the fact that the elimination of sugar increased in proportion as the general symptoms consequent upon the thyroidectomy became more pronounced.

The significance of pentosans as a source of energy in the animal organism, P. SCHIMOKICH (*Biochem. Ztschr.*, 55 (1913), No. 5-6, pp. 370-392).—In the respiration experiments here described, fixed quantities of arabinose or of grape sugar were given to a dog, sometimes in addition to a regular diet and sometimes during fasting.

It was found that both arabinose and grape sugar decreased the oxidation of the animal. The effect of arabinose was much greater than that of grape sugar and was more noticeable when the material was given with a normal diet than during fasting. It was also observed that arabinose did not affect the processes of oxidation immediately after resorption, although from 40 to 50 per cent of the dose was retained in the body. This fact suggests the possible storage of arabinose in combination with other molecules, analogous to the formation of glycogen from the hexoses.

The biological significance of phosphorus to the growing organism.—I, Investigations into the influence of phosphorus on the development of animals and on the metabolism of phosphorus and nitrogen, M. MASSLOW (*Biochem. Ztschr.*, 55 (1913), No. 1-2, pp. 45-62).—The work here reported was done with young dogs, metabolism experiments being combined with analyses of all body tissues after death. Control animals were given a normal diet; others received cow's milk; others diets rich in protein, fat, and carbohydrates, but poor in phosphorus; and still others the same diets but with sodium phosphate, calcium glycerophosphate, and lecithin added.

None of the experimental diets was able to sustain life for more than a few weeks after the puppies had reached the age at which a mixed diet would be normally received.

Concerning phosphates, A. MAYBAUM (*Ztschr. Gesam. Getreidew.*, 5 (1913), No. 8, pp. 229-237).—According to the author, the diet of the well-to-do, which contains materials rich in phosphorus, such as vegetables, eggs, milk dishes, and meat of different sorts, supplies the body with more phosphorus than it needs, and so the kind of bread which is used is not a matter of importance. In general, he believes that the diet, even of those in straitened circumstances, supplies phosphorus enough, and therefore there is no reason for substituting black bread for white bread, since the excess of phosphorus which the black bread supplies is not needed, while the nitrogenous material and carbohydrates which the black bread supplies in smaller quantity than the white are both valuable and necessary.

Observations during training of a rowing crew, A. LEHRNBECHER (*Arch. Hyg.*, 81 (1913), No. 1, pp. 1-42, fig. 1).—The author, himself a member of the crew, made careful observation of the body weight, temperature, pulse rate, and urine of rowers during 6 weeks' training for a race. Fatigue was also studied by means of the dynamometer, measurements of skin sensitiveness, and simple arithmetical tests. Subjective impressions were noted in connection with the psychology of training.

It can not be denied, the author points out, that rowing in races involves certain dangers. Even with most careful selection of the men, overstraining of the heart, nervous disturbances, and the like may occur. Careful training,

however, removes such risks. The control of body as well as mind, involved in the race, the author regards as valuable discipline.

The influence of fatigue on the amounts present in blood serum of dialyzable compounds showing triketohydrindene hydrate reaction, E. ABDERHALDEN and A. E. LAMPÉ (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 85 (1913), No. 1-2, pp. 136-142).—Following the previously described method for detecting amino acid in blood serum (E. S. R., 26, p. 804), the authors tested the blood of dogs before and after violent exercise in a treadmill, but were unable to note any characteristic differences in the amino acid content of the 2 types of serum.

The influence of the cerebrum on the metabolism of matter and energy, K. HANNEMANN (*Biochem. Ztschr.*, 53 (1913), No. 1-2, pp. 80-99).—The respiration and calorimetric experiments here reported were made with laboratory animals (frogs). In one series, the entire cerebrum was removed, in another the cerebral hemispheres; and in a third the optical lobe. The author summarizes his results as follows:

(1) The removal of the entire cerebrum, the hemispheres, or the optical lobe, produced a marked increase in the gaseous exchange, which lasted for several days. (2) The oxygen as well as the carbon dioxid output was increased, the carbon dioxid increase being the greater save in those cases where the hemispheres alone had been removed. (3) Calorimetric observations showed that an increase of heat production accompanied the increased gaseous exchange.

The application of the second principle of thermodynamics to the processes in the animal organism, J. BÁRON and M. PÓLÁNYI (*Biochem. Ztschr.*, 53 (1913), No. 1-2, pp. 1-20).—A theoretical technical discussion of the theorem that "every isothermal physical and chemical process occurring in nature takes place in such wise that the free energy in the body concerned is lessened," with special reference to the transformations of energy in the animal organism.

Combustion calorimetry and elementary analysis with the calorimetric bomb, M. DIAKOW (*Biochem. Ztschr.*, 55 (1913), No. 1-2, pp. 116-123).—A technical article dealing with improved methods in the use of the Berthelot bomb in the analysis of urine and other materials.

ANIMAL PRODUCTION.

Feed control officials' convention (*Amer. Hay, Flour, and Feed Jour.*, 24 (1913), No. 1, pp. 19-34, figs. 10).—An account of the fifth annual convention of the Association of Feed Control Officials, held at Washington, D. C., November 17 and 18, 1913. Addresses were given on the following subjects: Screenings and weed seeds as adulterants in commercial feeds; observations relating to British feeding stuffs; the feed industry in the United States; and the composition of cotton-seed meal.

The composition of cotton-seed meal, G. S. FRAPS (*Amer. Hay, Flour, and Feed Jour.*, 24 (1913), No. 1, pp. 28-31).—In this paper, which was presented at the fifth annual convention of the Association of Feed Control Officials, the need of a fiber standard for cotton-seed meal in addition to the protein or fat standards is pointed out. It is shown wherein these latter standards alone permit the admixture of hulls with the meal, thus reducing its feeding value, though remaining within the bounds of a guaranteed protein analysis.

[Analyses of feeding stuffs] (*Min. Agr. et Trav. Pub. [Belgium], Off. Rural Raps. et Communs.*, 1913, No. 7, pp. 107, 108, 124-126).—Analyses are reported of cotton-seed meal, linseed meal, cacao hulls, perilla cake, and sugar beets.

Feeding stuffs (*Verslag. en Meded. Dir. Landb. Dept. Landb., Nijv. en Handel, 1913, No. 5, pp. 28-40*).—This includes analyses as to the protein and fat content of linseed cake, rape cake, cotton-seed meal, peanut cake, sesame cake, soy-bean cake, coconut cake, palm-nut cake, corn germ cake, gluten meal, and molasses cake.

Phosphate feeding to animals, A. GOUIN and P. ANDOUARD (*Jour. Agr. Prat., n. ser., 25 (1913), No. 26, pp. 809, 810*).—The authors disagree with the general conclusions of previous investigators that the natural phosphates are not assimilable by the animal body. They state that this depends mainly upon the age of the animal and cite the assimilation of phosphorus salts by young animals in their skeletal growth.

The growth of animals, C. J. DAVIES (*Live Stock Jour. [London], 78 (1913), Nos. 2065, p. 435; 2066, p. 459; 2067, p. 483*).—The approximate average increase in height or weight of various growing animals during the first 6 months is given as follows: Fourteen-hand horse, $\frac{1}{2}$ in. per week in height at withers; cattle 2 lbs. daily; sheep, goat, and pig, 8 oz., 6 oz., and 12 oz. daily, respectively; St. Bernard dog 8 oz. daily, field spaniel 2 oz., Scottish terrier 1 oz., toy spaniel $\frac{3}{4}$ oz.; cat, rather more than $\frac{1}{2}$ oz. per day; rabbit, large varieties $\frac{3}{4}$ oz., small varieties $\frac{1}{2}$ oz. daily; guinea pig, $1\frac{1}{2}$ oz. per week up to 4 months old, when growth slackens; fowl $\frac{1}{2}$ oz. per day, more or less according to breed; duck $\frac{3}{4}$ oz. per day; and pigeon, nearly $\frac{1}{2}$ oz. daily during the first month.

Economic factors in cattle feeding.—III, A review of beef production in the United States, H. W. MUMFORD and L. D. HALL (*Illinois Sta. Circ. 169, pp. 28, figs. 6*).—The previous numbers of this series have been reported (*E. S. R., 28, pp. 72, 365*).

The authors review the history and development of the beef production industry in America, beginning with the early part of the nineteenth century in southern Ohio, thence throughout the Mississippi Valley, and finally by reason of the extension of railroads and the invention of the refrigerator car and tin can into the remote western States. While the period from 1867 to 1900 shows an increase in the number of cattle on farms and ranges of 48,000,000 the last decade has shown a slight decrease. This decrease is accentuated by the rapid increase in population, the proportion of cattle to population being 75 per cent in 1910 as compared to 84 per cent in 1890. The valuation of cattle in the United States has increased \$129,000,000 in 7 years, but the export of meat products has been reduced to an almost negligible amount due to home consumption.

Data taken from the Thirteenth Census are cited to show that while more than two-thirds of the cattle other than milch cows are west, more than two-thirds of the population are located east of the Mississippi River. Chicago and cities west of there have developed as the great cattle markets of the country. Kansas City outrivals all other centers as a feeder market, both as to the actual number shipped out and the proportion of feeders to total shipments. Statistics gathered in 1903^a indicated that only one-half of the 13,000,000 cattle marketed for slaughter that year were slaughtered in large central markets.

It is shown that while there has been a decrease in the number of cattle on the range, this section is undergoing a transition which may result in increased production in the future.

Reviewing the cattle situation in Mexico and Canada the authors do not regard these countries as being immediately available as sources of meat supply. It is believed that the Southern States offer abundant opportunities for the promotion of stock raising.

^a U. S. Dept. Com. and Labor, Rpt. Comr. Corporations on Beef Indus., 1905, pp. XXXVI + 315.

Steer feeding, J. C. BURNS ET AL. (*Texas Sta. Bul.* 159, pp. 5-34, figs. 12).—Continuing previous work (E. S. R., 28, p. 169), four lots of seven 2-year-old steers each, weighing approximately 850 lbs., were fed for a period of 139 days on the following rations: Lot 1, 2 lbs. cotton-seed meal, 20 lbs. cotton-seed hulls; lot 2, 2 lbs. cotton-seed meal, 24 lbs. silage (mainly sorghum and cowpea, partly corn); lot 3, 2 lbs. cotton-seed meal, 10 lbs. cotton-seed hulls, 12 lbs. silage; lot 4, 3 lbs. cotton-seed meal, 24 lbs. silage, with results as follows:

Summary of steer-feeding experiments.

Lot.	Average daily gain per head.	Cost of feed per pound of gain.	Shrinkage per lot.	Average dressing percentage.	Net profit per steer.
	<i>Pounds.</i>	<i>Cents.</i>	<i>Pounds.</i>	<i>Per cent.</i>	
1	2.61	5.90	177	58.03	\$14.32
2	2.29	5.19	105	59.19	20.01
3	2.49	6.17	138	58.92	15.84
4	2.26	4.98	107	58.54	18.70

It is estimated that 1.67 tons of silage are equivalent to one ton of cotton-seed hulls in feeding value, also that cotton-seed meal at \$27 per ton is more profitable than cotton seed at \$17 per ton in supplementing silage to form a fattening ration. From these and former experiments it is concluded that a combination of cotton-seed meal and silage is the most profitable ration that can be used for feeding cattle in Texas.

In another experiment 2 lots of 16 steers each, weighing approximately 775 lbs., were fed for a period of 139 days on a basal ration composed of cotton-seed meal, ground milo maize or Kafir corn, and silage; lot 1 receiving cotton-seed hulls, lot 2, sorghum hay, the same quantity being fed to each lot. In this trial lot 1 made an average daily gain of 2.97 lbs. per head, at a cost of 8.93 cts. per pound gain, and yielding a net profit of \$4.86 per head; lot 2, 3.1 lbs. gain, cost 9.08 cts., and profit \$4.10. In addition profits from hogs following the steers were credited to the steers at \$3.95 a head.

It is estimated that 100 lbs. sorghum hay is equivalent to 105 lbs. cotton-seed hulls.

Beef making in southern Texas, J. E. WING (*Breeder's Gaz.*, 64 (1913), No. 21, pp. 984, 985, figs. 2).—An account of beef production methods in the tick-infested section of southern Texas. Zebu are crossed on Shorthorn, Hereford, and grade cattle, the Herefords being deemed preferable. The offspring develop fast and as yearlings are said to weigh 1,000 lbs. and as 2-year-olds 1,700 lbs. The half-blood calves do not develop the hump nor the dewlap of the zebu. Because of the natural adaptability of the zebu to southern Texas conditions an effort is being made to fix a type intermediate between the Indian cattle and the natives.

Value of Oldenburg marsh pasture, M. PORR (*Landw. Jahrb.*, 44 (1913), No. 3, pp. 441-517, fig. 1).—This is a report of 3 years' experiments in feeding cattle on Oldenburg marsh pasture, a mixture of white clover, rye grass, timothy, and meadow barley. The average feeding period for 2- and 3-year-old steers was 167 days; the average daily gain approximately 1.1 kg.; the feed number or number of kilograms of live weight supported per hectare during the entire pasture period, 208,239; and the fat number or kilograms of gain per day per hectare, 2.81. The first period of pasturing, consisting of 92 to 124 days, showed an average daily gain per hectare of 3.39 kg.; while the second period of 39 to 81 days showed a gain of 1.73 kg., thus indicating the greater value of the pasture during the first two-thirds of the entire feeding period.

In the winter feeding of steers on hay from these pastures the weights of the animals were retained to better advantage than those fed oat, wheat, and barley straw in various proportions.

The average pasture period for milch cows was 175 days; the feed number 171,187; the milk yield per day per hectare 19.47 kg.; the butter yield per day per hectare 0.68 kg.; the average increase in weight per cow 41.6 kg.; and the average value of skim milk and butter proceeds per hectare in 180 days 401.38 marks.

It is estimated that the average annual proceeds per hectare of pasture land was 387.68 marks and of tillable land 899.74 marks.

Color in Shorthorn cattle, E. N. WENTWORTH (*Amer. Breeders Mag.*, 4 (1913), No. 4, pp. 202-208, fig. 1).—In commenting on the theories on color inheritance advanced by several investigators, the author calls attention to the possible sources of error in computation from matings. He estimates the possible error at from 35 to 40 per cent. These errors have arisen through incorrect recording of colors, largely because of color fashions, and the tendency of breeders to report only fashionable colors so far as possible. He considers roan a mosaic, believing it to be "a simple dominant pattern consisting of an irregular arrangement of red and white hairs. It varies in amount of white within itself, hinting at the fact that it is probably not a single unit but complex."

Report of the American Bison Society (*Ann. Rpt. Amer. Bison Soc.*, 6 (1913), pp. 61, figs. 18).—The report of this society, whose object is the permanent preservation and increase of the American bison, states that a census of the American bison in North America in January, 1913, indicates that there are captive in the United States 1,651 head, in Canada 1,303, and wild in North America 499, making a total of 3,453. A herd has recently been established on the Niobrara Reservation in northern Nebraska.

The breeding of caracul sheep, A. GOLF (*Tropenpflanzer*, 17 (1913), No. 11, pp. 593-602).—In this article the author outlines the general advantages of the caracul breed of sheep, both as to wool-bearing qualities and native hardiness, and discusses the advantages ensuing from the crossing of these on the native sheep of Dutch East Africa.

Strange sheep of Asiatic Russia, C. C. YOUNG (*Amer. Breeders Mag.*, 4 (1913), No. 4, pp. 184-192, figs. 6).—An account of the native sheep of Asiatic Russia.

These sheep are mostly brown or black in color and are noted for their great hardiness and digestive abilities. There are 2 principal types, the fat-rumped (Kurdiuk) type (*Ovis steatopyga*) and the broad-tailed species (*O. platyura*). The caracul breed belongs to the latter. The purpose of the introduction of this breed into the United States is for fur raising and to improve the hardiness and mutton qualities of the short-wooled breeds. The fat-rumped type is said to be the heaviest of all known sheep. It is red in color, has coarse stiff wool like our mountain sheep, and "the tail consists of only 3 or 4 vertebrae, generally atrophied, with 2 immense symmetrical fat lobules covering the buttocks and extending below the knees, weighing from 20 to 40 lbs., long pendulous ears, decidedly convex nose, and a very large head."

The sheep and wool industry, H. D. BAKER (*Daily Cons. and Trade Rpts. [U. S.]*, 16 (1913), No. 289, pp. 1256, 1257).—An account of the breeding of fat-tailed sheep in Afghanistan and of the economic value of this breed in providing food, grease, and wearing apparel to the natives.

On account of its good quality of wool the Afghanistan sheep are occasionally crossed with Indian sheep and the wool of these cross breeds appears to be of fine quality and long. It is reported that attempts to cross the fat-tailed

and Merino breeds of sheep have met with difficulty owing to the aversion of one breed for the other.

Spanish goats, H. H. MORGAN (*Daily Cons. and Trade Rpts.* [U. S.], 16 (1913), No. 283, p. 1167).—It is reported that there are upwards of 3,500,000 goats in Spain. These goats weigh from 55 to 96 lbs., and the daily average milk yield is a little over 2 qt. per goat. The animals are said to be fed entirely on dried alfalfa and beans, live to the age of 15 or 16 years, and are productive at the second year. The finest breed of goats and those producing the largest quantity of milk are raised in Murcia Province, south of Alicante. Large numbers are slaughtered for home consumption and the exports of goat skins are heavy.

Steamed and dried potatoes, VON HERTZBERG-HOHBÜCH (*Deut. Landw. Presse*, 40 (1913), No. 89, p. 1059).—A brief account of successful swine-feeding trials with steamed and dried potatoes.

Horse breeding in New Jersey, F. C. MINKLER (*Ann. Rpt. N. J. Bd. Agr.*, 40 (1912), pp. 29–36).—A general discussion on the type of horse required for New Jersey conditions and on methods of horse improvement through community breeders' associations, etc.

Distribution of public service stallions enrolled in the counties of Wisconsin during 1913, A. S. ALEXANDER (*Wisconsin Sta. Circ. Inform.* 45, pp. 97).—This circular lists the enrolled stallions in Wisconsin by counties, together with a text of the Wisconsin stallion law, with amendments and additions. It is shown that a total of 1,704 pure-bred stallions and 1,712 grade and mongrel or scrub stallions are enrolled for public service in the State. The number of pure breeds is constantly increasing, while the grades and scrubs are decreasing in number.

The commercial fattening of poultry, A. R. LEE (*U. S. Dept. Agr. Bul.* 21, pp. 55, pls. 5).—This is a continuation of work previously noted (*E. S. R.*, 26, p. 76).

The average cost and amount of feed consumed in fattening 394,744 chickens at the 4 feeding stations during the season of 1911 were, respectively, as follows: Grain per pound of gain, 3.62, 3.33, 4.45, and 4.18 lbs.; cost of feed per pound of gain, 7.83, 7.2, 7.15, and 8.71 cts.; total cost per pound of gain, 9.18, 9.2, 8.96, and 10.27 cts. The averages in 1912 for 498,681 chickens were: Grain per pound of gain, 4.42, 3.58, 3.72, and 4.98 lbs.; cost of feed per pound of gain, 8.74, 7.7, 6.61, and 9.95 cts.; total cost per pound of gain, 10.37, 9.69, 7.98, and 11.54 cts.

It was found that "tallow, while making the fat on the birds more pronounced, increased the cost of gains. Thick condensed buttermilk in place of tallow produced better results. Oat flour produced greater gains than low-grade wheat flour, but the latter feed produced cheaper gains. Beef scraps added to the buttermilk in a fattening ration did not increase the gain. The addition of condimental feeds did not increase the appetite of the birds or help the gains. Grit is of no value in fattening for any period under 15 days. Under commercial conditions in the Middle West the best results are secured by fattening for about 14 days until the middle of September, and then gradually shortening the period to 6 or 7 days. The birds ate more feed on three feeds a day but used feed more efficiently when fed only twice.

"Mechanical labor-saving devices reduced the cost of fattening by reducing both the total amount of labor and the proportion of skilled labor required. The portable feeding battery turned out the birds in better condition and reduced the cost of labor per pound of gain. Gains were produced at 1.89 and 1.41 cts., respectively, per pound cheaper in 1911, and 6.3 and 2.68 cts. less in 1912 on broilers than on roasters, in 2 experiments.

"There was great variation in the results secured in fattening. This was due to the difference in the ability of the birds to take on flesh, to their weight, and to the effect of weather conditions. The variation in birds makes their selection in fattening of considerable importance, if the labor of the extra work can be handled economically. The influence of the weather in fattening allows a chance of error in comparing fattening experiments conducted at different times. The bleach produced by fattening with buttermilk varies according to the amount of milk solids consumed by the birds.

"The average cost of fattening hens in November and December was 10.92 and 8.74 cts. in 1911, and 10.83 and 10.43 cts. in 1912, respectively, per pound of gain at two stations. This is higher than the average cost of fattening chickens for the entire season at the same stations but less than the cost of fattening chickens in November and December. Hens cost 7.7 cts. per pound in 1911 and 10.3 cts. in 1912, into the feeder, so that their flesh can be bought cheaper than produced at this time of the year. Cheaper gains were secured in fattening hens in 1911 on the rations used in fattening chickens than on a ration of corn chop with 15 per cent of shorts mixed with buttermilk.

"Chickens cost 17.6 cts. per pound into the feeder in July, 1911, while the gains cost 7 cts. per pound at this time; in November, 1911, they cost 9 cts. per pound into the feeder, and the gains cost 10.5 cts. per pound. This influences the profit in fattening and the best length of time to fatten, making it advisable to feed longer in the first part of the season. The cost of picking, grading, and packing (including freezing) was about 7 cts. per head, making the total average cost of a pound of dressed poultry in July 20.5 cts., which gradually decreased through the season to 13.1 cts. in November, 1911.

"The best results were secured with the following 3 rations: No. 1, corn meal, low-grade wheat flour, and shorts 3:2:1; No. 2, corn meal and low-grade wheat flour 3:2; and No. 3, corn meal, low-grade wheat flour, and shorts 5:3:1, and 5 per cent of tallow. The same feeding value is secured in a ration of corn meal and oat flour 3:2 but at an increased cost of 37 cts. per 100 lbs. of gain. Corn meal, low-grade wheat flour, and shorts 4:2:1, gave very good results during the latter part of the feeding season, or in cool weather; that is, the proportion of corn meal and low-grade wheat flour may be increased in cool weather."

The origin of the "systems of selecting layers," J. H. ROBINSON (*Farm Poultry*, 24 (1913), No. 12, pp. 246-248).—Comments are made on the reliability of the Hogan method of selecting laying hens and determining their capacity for laying (E. S. R., 30, p. 270).

Fifth Annual Conference of Poultry Farmers (*Dept. Agr. N. S. Wales, Farmers' Bul.* 71, 1913, pp. 25).—This includes a report of the conference, together with papers on the following subjects: Quality as a factor in production; the cost or rearing; management, housing, and confinement; wart disease; and the limitations of egg production. In the last paper the author calls attention to the dangers ensuing from forced egg production, among others to the deterioration in the quality of eggs, ovarian troubles, faulty incubation, and weakly chickens.

The poultry industry in the United States, H. R. LEWIS (*Ann. Rpt. N. J. Bd. Agr.*, 40 (1912), pp. 81-92, pls. 6).—A discussion on the poultry industry in the United States in general and New Jersey in particular. Items included are selection, feed, care and management, desirable rations, and poultry house construction.

A remarkable hybrid (*Country Life* [London], 34 (1913), No. 882, p. 761, fig. 1).—An account of a hybrid between a black-winged peacock and a domestic hen, this being the second known cross of this kind.

Ostrich foods and feeding, W. G. DOWSLEY and C. GARDNER (*Grahamstown, So. Africa* [1913], pp. VII+189).—This volume treats in detail on the breeding, feeding, care, and management of the ostrich for commercial purposes.

Further experiments on ovarian transplantation in guinea pigs, W. E. CASTLE and J. C. PHILLIPS (*Science, n. ser.*, 38 (1913), No. 987, pp. 783-786).—These studies are a continuation of work previously reported (*E. S. R.*, 25, p. 867).

The ovaries of a light cinnamon guinea pig were transplanted into the body of a brown one, and the grafted animal was mated with an albino male. She produced 3 albinos and 2 colored, both cinnamon. The albino offspring proved to be potential cinnamons, having inherited cinnamon from the graft contained in the foster mother. Further tests indicated that these offspring were merely heterozygous in cinnamon, since the father was albino and did not transmit cinnamon. A cinnamon female offspring when mated with her albino father produced among others a cinnamon young, thus not only inheriting this color herself but transmitting it to her offspring. It is stated that this evidence indicates that "in the higher animals germinal substance and body are physiologically distinct, and that the genetic potentialities of the latter are not subject to modification through somatic influence."

A large number of grafts were made. Difficulty was experienced in making successful transplantations, due to the intolerance of the body to foreign tissue.

Color, sex, and fertility: Their relationship in guinea pigs, PRÉVOT (*IV. Conf. Internat. Génétique Paris, Compt. Rend. et Raps.*, 1911, pp. 511, 512).—It was observed that in furs of guinea pigs in which white is the predominant color, females preponderate to the extent of 58.6: 41.3. In all other types of coloring, males predominate, the numbers varying from 53 and 55 per cent males to 45 and 47 per cent females. White guinea pigs were the most fertile, and those types nearest to the wild type the least prolific. It was found that the yellow guinea pig is completely sterile, as has been observed in the case of yellow mice.

DAIRY FARMING—DAIRYING.

The cost of raising a dairy cow, C. M. BENNETT and M. O. COOPER (*U. S. Dept. Agr. Bul.* 49, pp. 23, figs. 6).—Cost records were kept during 1908-1912, inclusive, of Jersey heifers on a Wisconsin dairy farm. During the 5 record years 117 calves were handled, 73 being fed the full period of 2 years. The quantity of each feed consumed was obtained by actual weighing, the prices being the local prices of feeds at the farm as reported at the end of each month. During the first year the calves were fed whole milk about 30 days, then gradually turned to skim milk with the addition of an increasing amount of grain mixture (bran, oats, and oil meal, 4:5:1), clover-mixed hay, alfalfa, and corn silage. The average quantity of feed consumed per head during the first year was whole milk 342 lbs., skim milk 3,165 lbs., mixed hay 857 lbs., corn silage 353 lbs., grain mixture 547 lbs., pasture 123 days. Of the total cost, \$24.58, whole milk comprised 21.3, skim milk 25.7, and grain mixture 28.2 per cent.

The average man labor per head per year was 39.9 hours and horse labor 3.5 hours, making a total cost of \$5.14, when man labor is estimated at 12 cts. per hour and horse labor 10 cts. The first 2 months were the most expensive, the combined cost of feed and labor for this time being 32.5 per cent of the yearly cost.

During the second year, pasture, mixed hay, corn silage, and corn stover were fed at their appropriate times during the year. The average quantity of feed

consumed per head during the second year was mixed hay 1,120 lbs., corn silage 3,250 lbs., corn stover 672 lbs., and pasture 171 days. The total feed cost for the second year was \$16.11. Man labor was estimated at 23.25 hours and horse labor 0.75 hour per head, costing a total of \$2.86, and making the total cost of feed and labor for the second year \$18.97. The initial value of a calf, \$7.04, based on the cost of maintaining 2 herd bulls, together with other costs, brought the total cost of a dairy heifer 1 year old to \$42.52, or a net cost of \$39.52, crediting manure at \$3. The average total cost of a 2-year-old heifer was \$69.41, or \$61.41 crediting manure at \$8. Of these costs it was found that feed comprises 65.5 per cent, labor 12.5, and all other costs 22 per cent of the total cost of a dairy heifer at 2 years. "It would appear that a farmer can not afford to raise a heifer calf that will not sell for more than \$60 at 2 years of age."

Escutcheon theory in milkers (*Live Stock Jour.* [London], 78 (1913), No. 2067, p. 489, figs. 15).—Comments on the Guenon theory on the relation between escutcheon and milk yield are given, with illustrations showing the extent to which the escutcheon may be modified by the influence of either parent, the difference in its value according to the breed in which it is found, and other difficulties which beset the student of the Guenon theory.

On the Normandy breed of cattle, HÉDIARD (*Indus. Lait.* [Paris], 38 (1913), No. 49, pp. 781-795).—The average milk yield of this breed is estimated at from 16 to 19 liters (16.9 to 20 qts.) per day, and the average butter production at 832 gm. (1.83 lbs.) per day with a maximum of 1.717 kg. The adaptability of this breed to French conditions is discussed and its improvement and breeding advocated.

Russian milch cows, N. E. HANSEN (*Chicago Dairy Produce*, 20 (1913), No. 30, p. 19).—A brief account of the Kirghiz cattle of southern Siberia, which are said to be immune to tuberculosis and produce a considerably higher percentage of milk fat in their milk than any other known breed. The possibility of transferring this immunity to other breeds by crossing is considered.

On the feeding value of fermented sugar-beet tops for dairy animals, A. MORGEN, C. BEGER, and F. WESTHAUSSER (*Landw. Vers. Stat.*, 79-80 (1913), pp. 637-666).—In experiments with milking sheep and goats, in which ensiled sugar-beet tops were compared with an ordinary ration of hay, corn, meal, gluten meal, and oil meal as milk producers, it was found that the beet tops were an insufficient feed and failed to keep up the milk yield. A combination feed of the ordinary ration and beet tops proved most effective. The feeding of sour milk in quantity proved detrimental to milk production.

Beet tops in relation to the microflora and sanitation of milk, C. GORINI (*Molk. Ztg.* [Hildesheim], 27 (1913), No. 86, p. 1666).—In feeding both fresh and soured beet tops to dairy cattle, the number of gas-forming bacteria in the milk was found to be high. With beet tops which had been subjected to a drying temperature milk was produced showing a lower germ content, especially of the putrefactive bacteria. The digestive tract and the feces were similarly affected. The number of germs was still further lowered on feeding completely sterilized beet tops.

Milk hygiene, C. J. MARSHALL (*Penn. Live Stock Sanit. Bd. Circ.* 25, 1913, pp. 32, pl. 1, figs. 9).—This circular includes a general summary of the necessary requirements for milk hygiene, together with brief notes on the selection of cows, grooming, caring for sick cows, feeding, watering, and handling the milk. There are also included general plans of construction for stables, milk houses, and ice houses.

The improvement of the milk supply in the towns of the United Provinces of Agra and Oudh, H. R. C. HAILEY (*Dept. Land Rec. and Agr. United Prov.*

Agra and Oudh, Agr. Ser., 1913, Bul. 29, pp. 14).—Among the remedies proposed for the improvement of the town's milk supply are those of municipal control and management of dairies, community breeding schemes, and provisions for town pastures. It is stated that in these Provinces the main difficulties in the way of development of the milk industry for supplying large towns consist of (1) the small capital of the dairymen and the absence of any form of association among them, (2) the want of proper accommodations, (3) the poverty of most of the breeds of cattle of these Provinces as milkers, (4) the absence of grazing ground for dry cattle, and (5) the scarcity and high price of fodder.

Certified milk, T. C. McCLEAVE (*Jour. Amer. Med. Assoc., 61 (1913), No. 23, pp. 2031-2035*).—An account of the origin and development of the certified milk movement, together with a detailed discussion of the methods of organizing and the duties of city milk commissions.

[Reports of the state dairy and food commissioner and the state chemist on dairy products], W. HANSON and H. HARMS (*Bien. Rpts. State Dairy and Food Comr., State Chem., and State Dairy and Food Bur. Utah, 1911-12, pp. 29-36, 79-105*).—These reports discuss the enforcement of the state laws relative to the sale of dairy products in Utah, including a special report on shrinkage in butter.

Weighings of 15 samples of butter showed an average loss in moisture in 6 weeks of 2.78 per cent. Fifteen other samples showed after about 1 month a loss of 2.18 per cent of moisture, while 5 samples of cold storage butter lost 1.34 per cent.

Daily changes in the specific gravity and fat content of milk, KLOSE (*Milchw. Zentbl., 42 (1913), No. 13, pp. 385-392*).—The specific gravity and fat content of morning, noon, and night milkings were taken daily for several months in a herd of 70 milch cows.

The daily changes in specific gravity ranged between 0 and 0.0037 and in fat between 0 and 0.7 per cent. During March 10 per cent of the changes in specific gravity ranged between 0.001 and 0.0019 and 18.9 per cent of the fat changes between 0.2 and 0.45 per cent. In May 33 per cent of the specific gravity changes were between 0.001 and 0.0017, and 30 per cent of the fat changes between 0.2 and 0.5 per cent. In July 31.1 per cent of the specific gravity changes were between 0.001 and 0.0037, and 34.4 per cent of the fat changes between 0.2 and 0.7 per cent. In October 10 per cent of the specific gravity changes were between 0.001 and 0.0018, and 34.4 per cent of the fat changes between 0.2 and 0.5 per cent.

The elimination of artificial coloring matter by the udder, P. SISLEY and C. PORCHER (*Compt. Rend. Acad. Sci. [Paris], 157 (1913), No. 17, pp. 729-732*).—Experiments were conducted on she goats with various coloring materials.

Uranium produced only a slight trace of coloring in the urine, both when taken into the stomach and when injected into the jugular vein. No change was noted in the milk and it is concluded that the udder opposes the passage of certain substances. Rhodamin when taken into the stomach produced rose-colored milk after 10 hours. After that the coloring rapidly diminished. The coloring was also present in the urine. The proportion of rhodamin present in the milk was small compared with the amount taken into the body. One gm. of methylene blue produced no effect on either the milk or urine; 3 gm. produced a trace in the milk and urine. Ponceau taken into the stomach showed no presence in the milk. With dimethylamino-azobenzene, the milk showed a rose coloration on the addition of a small quantity of HCl. However, the elimination was transient.

These results confirm earlier investigations (Déchavanne, 1909). They indicate first, the very diffusibility of these coloring matters in the animal body;

second, the course of assimilation; and third, the filtering ability of the mammary glands. These glands seem to possess a resistance to some substances and not to others.

Influence of fertilizing and feeding on the milk constituents. O. ALLEMANN (*Abs. in Molk. Ztg. [Hildesheim], 27 (1913), No. 86, p. 1666*).—Various quantities of iron lactate, calcium sulphate, the phosphates of calcium, magnesium, and sodium, sodium chlorid, potassium chlorid, and potassium nitrate were fed to milch cows with their regular grain and hay ration.

The inorganic salts showed no influence on the milk constituents. The feeding of a large quantity of beets increased the volatile fatty acids. Feeds such as sesame cake increased the quantity of oleates in the milk fat. Feed from heavily fertilized land resulted in no change in the composition of the ash content of milk. The fat and sugar content of milk proved to be independent of either fertilizing or feeding. No relation was observed between the curd content of milk and fertilizing.

The influence of work on the milk yield and fat content (*Milchw. Zentbl., 42 (1913), No. 14, pp. 429-432*).—Cows were worked during 9 to 10 hours each day with the result that their milk yield was decreased, while the content of dry substance and fat in the milk was increased over the amounts obtained during a rest period.

The milk of cows in heat, H. STENG (*Arch. Hyg., 78 (1913), No. 6, pp. 219-247; abs. in Centbl. Bakt. [etc.], 2. Abt., 39 (1913), No. 4-7, p. 133*).—Results of tests indicate that there is a change in the chemical composition of milk during the period of estrum, although the change is not uniform. The fat content is often lowered, especially on the following day. The milk sugar content and refraction remain the same or are slightly increased. The acid quantity is somewhat increased and the milk becomes sour more rapidly during this period. The specific gravity is changed with difficulty. The milk at this time is thought to contain a toxin (ovariotoxin) which is the cause of a form of digestive trouble in infants.

[Reagent for detecting freshness in cows], H. SCHEEL (*Eignet sich die Schardingerreaktion zur Feststellung des Frischmilchendseins der Kühe? Inaug. Diss., Tierärztl. Hochschule, Hannover, 1912; abs. in Milchw. Zentbl., 42 (1913), No. 13, pp. 393, 394*).—Tests were made of a formalin methylene blue solution known as Schardinger's reagent.

It was found that the foremilk of cows fresh in milk failed to discolor the reagent in less than 30 minutes. Milk of cows in advanced lactation in most cases discolored the reagent, the foremilk in 30 minutes and the strippings in 12 minutes. The reaction is altered by the time of milking, the condition of the udder, and other factors, thus rendering a diagnosis as to the freshness of cows by this reagent indecisive.

Changes undergone in the milk of cows infected with foot-and-mouth disease, O. MEZGER, H. JESSER, and K. HEPP (*Ztschr. Untersuch. Nahr. u. Genussmtl., 25 (1913), No. 9, pp. 513-551*).—It was observed that at the beginning of the disease there was a concentration of the milk, especially as to the content of fat and nitrogenous material, and frequently of the ash, chlorin, and phosphoric acid, while the milk quantity decreased. With the improvement of the animal, the milk quantity and the milk sugar content increased, while the fat and nitrogenous material were lowered. It was noted that the higher the milk sugar and ash content, the higher was the refraction of the serum. The observations of other investigators are noted.

[Composition of condensed milks], J. C. BRUNNICH (*Ann. Rpt. Dept. Agr. and Stock [Queensland], 1912-13, p. 77*).—Analyses of 47 samples of condensed

milks showed the following average composition: Cane sugar 41.88, fat 9.84, and milk solids-not-fat 23.63 per cent.

Process for producing desiccated milk, A. A. DUNHAM (*U. S. Patent* 1,074,419, *Sept. 30, 1913*; *abs. in Jour. Soc. Chem. Indus.*, 32 (1913), No. 21, p. 1027).—A report of a patent process by which "milk is partially evaporated at a temperature below the coagulating point of albumin, and then dried and subjected to a blast of hot air on a rotating cylinder heated internally to above the coagulating point of albumin."

The function of colloids and their relation to swell, R. M. WASHBURN (*Ice Cream Trade Jour.*, 9 (1913), No. 11, pp. 32, 33).—In discussing the effects of gelatin and similar colloidal substances in ice cream making, the author advances the theory that "the function of gelatin is primarily to form a closed capsule about the minute water crystal and thereby retard crystallization; and that the function of vegetable gum is chiefly to stick these many gelatin capsules together, thus holding the mass intact." It is further claimed that the contentions against the use of gelatin on the ground of increased swell are ill founded because of the inability of gelatin to produce this.

[Butter inspection], J. C. BRUNNICH (*Ann. Rpt. Dept. Agr. and Stock [Queensland]*, 1912-13, p. 55).—As the result of butter inspection it was found that 46.5 per cent of the samples contained boric acid as a preservative, ranging in amount from a trace to 0.8 per cent. The average moisture content of 289 samples of salted butter was 14.44 per cent and of 22 unsalted samples 14.79 per cent, the highest percentages being in the winter months and the lowest in the summer months.

Fat content of cheese, H. FINCKE (*Ztschr. Öffentl. Chem.*, 19 (1913), No. 22, pp. 430-433).—Inasmuch as the fat content of cheese, as based on the dry substance, ranges between 50 per cent for cream cheese to less than 10 per cent for skim-milk cheese, the author advocates a fat content standard for the different types of cheese ranging from 30 per cent for cream cheese to less than 5 per cent for skim milk, this to be determined on the entire cheese mass.

A comparison of the different methods of dividing the proceeds for milk at cheese factories, L. A. ZUFELT (*Ann. Rpts. Dairymen's Assocs. Ontario*, 1912, pp. 52-57).—An examination of the tests of 2 cheese factories indicated that no constant relation exists between the fat and casein in the milks of individual patrons, but that on the contrary the casein shows a greater variation than the fat. The results of manufacturing into cheese different milks containing varying amounts of fat and casein indicated first, that the straight "fat" method of payment approaches more nearly the actual value of the milk than the "fat+2" method when quantity alone is considered; and second, that the difference between the "fat" and "fat and casein" methods is so small as hardly to warrant the extra expense of a casein tester.

Reindeer milk and cheese, C. BARTHEL and A. M. BERGMAN (*Ztschr. Untersuch. Nahr. u. Genussmitl.*, 26 (1913), No. 5, pp. 238-241, figs. 2; *abs. in Chem. Zentbl.*, 1913, II, No. 18, p. 1606).—The average composition of reindeer milk is given as follows: Water 63.3, protein 10.3, fat 22.46, milk sugar 2.5, and ash 1.44 per cent. The average size of fat globules is 5 microns. The composition of cheese is water 28.81, protein 22.57, fat 44.02, other organic material 2.2, and ash 2.4 per cent.

VETERINARY MEDICINE.

[Veterinary work in foreign countries] (*Arb. K. Gsundheitsamt.*, 43 (1912), No. 3, pp. 313-453; 44 (1913), No. 4, pp. 608-728).—Accounts are presented of veterinary affairs in foreign countries, including organization, the kinds and

number of animals, inspection and traffic, veterinary police work, meat inspection, etc., as follows: In Switzerland, by Ströse (pp. 313-360); in Denmark, by Hall (pp. 361-435); in Egypt, by Zeller (pp. 436-453); in Sweden, by Hall (pp. 608-677); and in Italy, by Wehrle (pp. 678-728).

Annual report of the Punjab Veterinary College, Civil Veterinary Department, Punjab, and the Government Cattle Farm, Hissar, for the year 1912-13. H. T. PEASE, J. FARMER, and R. BRANFORD (*Ann. Rpt. Punjab Vet. Col. and Civ. Vet. Dept., 1912-13*, pp. III+2+15+XVII).—This is the usual annual report dealing with veterinary progress in Punjab, occurrence and treatment of contagious diseases, breeding operations, etc.

The phosphatids of the kidney. M. MACLEAN (*Bio-chem. Jour.*, 6 (1912), No. 4, pp. 333-354).—"The acetone insoluble phosphatids of the horse kidney are lecithin, cuorin, and a diaminomonophosphatid—carnaubon. All these are contained in the primary ether extract, while the subsequent alcoholic extract contains lecithin and carnaubon; cuorin, being insoluble in alcohol, is not present here. Thus, so far as solubility allows, the lipoids of the ether extract are the same as those present in the alcoholic extract. In the kidneys investigated, the ethereal extract contained much more cuorin than lecithin.

"A method is described whereby the complicated alcoholic extract can be purified from a nitrogenous substance. In all tissues investigated hitherto, the phosphatids of the alcoholic extract must have been contaminated by this substance; this explains many of the divergent results obtained. The diaminomonophosphatid isolated has all the properties of a substance found in ox kidney by Dunham and Jacobson, and called by them carnaubon. They state that this substance is a triaminomonophosphatid. It is probable that carnaubon is not a tri-, but a diaminomonophosphatid, and that the methods used for its isolation by Dunham and Jacobson were inefficient to obtain a pure substance. On extracting a substance obtained by the method employed by the above investigators with water, a diaminomonophosphatid was obtained."

Contributions to the biochemistry of growth.—The glycogen content of the liver of rats bearing malignant new growths, W. CRAMER and J. LOCHHEAD (*Proc. Roy. Soc. [London]*, Ser. B, 86 (1913), No. B 588, pp. 302-307).—"Glycogen disappears more rapidly from the liver of tumor-bearing rats than from the liver of a normal rat. Since observations on the gaseous metabolism showed that there is no increased oxidation of carbohydrate material in tumor-bearing animals, the results confirm the conclusion arrived at previously from observations on pregnant animals, that in growth carbohydrate material is used for the synthesis of protoplasm."

About some biological properties of the spleen in experimental nagana infection. P. RONDONI and G. GORETTI (*Ztschr. Immunitätsf. u. Expt. Ther.*, I, Orig., 17 (1913), No. 4, pp. 432-443).—It was found that the spleens from guinea pigs and rats affected with nagana were trypanolytic. No marked accumulation of immune antigens originating from trypanosomes in the spleen was noted. The spleen of these animals was found to have in vitro marked hemolytic (auto-, iso-, and heterolytic) properties, which is due to an increased amount of lipoids in the spleen.

About leucocyte-dissolving immune bodies. E. LESCHKE (*Ztschr. Immunitätsf. u. Expt. Ther.*, I, Orig., 16 (1913), No. 5-6, pp. 627-632, fig. 1).—By giving intravenous injections of leucocytes from various species of animals, i. e., man, horse, etc., specie-specific antileucocytic immune bodies are produced. These show agglutination, complement fixation, and cytolysis (incomplete) for leucocytes.

Immunizing against calves' rennet. S. G. HEDIN (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 77 (1912), No. 3, pp. 229-246; *abs. in Centbl. Bakt. [etc.]*, 1.

Abt., Ref., 53 (1912), No. 10, p. 292).—A study was made of the behavior of normal serum with rennet obtained from various animals, and the results show that the inhibition of rennet action is not specie specific. The immunization of rabbits with rennet zymogen (neutral infusion of the mucous membrane from the calf) at first shows a larger output of antirennet than when immunization is done with rennet. Only after immunizing over a long period of time are the results alike. The same antistubstance appears to be produced in both cases. The most important property of the antirennet and of the inhibitory substance in the zymogen is the specie-specific inhibition whereby they are distinguished from the inhibitory substances present in normal serum. The antibody is preserved better in the serum kept in vitro than in the animal body.

The relation of precipitins to complement, A. LEBAILLY (*Ztschr. Immunitätsf. u. Expt. Ther., I, Orig., 15 (1912), No. 6, pp. 552-575*).—It was possible by the fractional addition of antigens to precipitins to separate the complement fixation process from the precipitation process. According to this, in all probability the complement fixation does not belong to the precipitins but to the lytic amoceptors which accompany the precipitins.

The protecting influence of complement (alexin) upon protein metabolism, E. HEILNER and R. SCHNEIDER (*Ztschr. Biol., 59 (1912), No. 8, pp. 321-334*).—It has been previously shown^a that during anaphylactic shock protein metabolism is considerably reduced. In these experiments starving animals were injected with homologous and heterologous sera, and from the results it can be noted that complement (alexin) seems to have some relation to protein metabolism when viewed in the light of protective immunity. The presence of complement (protective enzyme) is necessary for the normal cycle of protein decomposition, and when the amount of complement is reduced, the decomposition increases proportionately.

In starving animals the regeneration of complement destroyed by the injection of foreign blood corpuscles does not occur any quicker than it does in normal animals. This is probably due to a destruction of the cells (but no definite group of cells) which produce the complement. After injecting 6 gm. of a foreign blood corpuscle suspension into animals, the amount of urine is greatly increased. No appreciable increase was noted when homologous protein was given.

The influence of giving sodium chlorid per os on the cycle of anaphylaxis, E. FRIEDBERGER and H. LANGER (*Ztschr. Immunitätsf. u. Expt. Ther., I, Orig., 15 (1912), No. 6, pp. 535-545*).—By the administration of large amounts of table salt per os, it is possible to prevent the anaphylactic symptoms which occur as a result of a second injection of a protein. The tests were conducted with normal and starving guinea pigs.

Is it possible to produce an anaphylatoxin-like cleavage product by allowing normal sera to act upon histidin? E. FRIEDBERGER and H. LANGER (*Ztschr. Immunitätsf. u. Expt. Ther., I, Orig., 15 (1912), No. 6, pp. 528-534*).—By the action of a normal guinea pig serum on histidin hydrochlorid at 37° C. it is not possible to produce a substance which is acutely toxic or lethal for guinea pigs.

The nature of antianaphylaxis, R. WEIL and A. F. COCA (*Ztschr. Immunitätsf. u. Expt. Ther., I, Orig., 17 (1913), No. 2, pp. 141-155*).—From some quantitative experiments it is concluded that antianaphylaxis, as held by Rosenau and Anderson, Wells, Friedberger, and Szymanowski, is strongly specific. It is concluded that antianaphylaxis is produced by the neutralization of specific antibodies.

Precipitation in meat poisoning, with an observation in regard to the occurrence of hemolysins against sheep blood corpuscles in paratyphoid B-Gärtner antiserum, A. ROTHACKER (*Ztschr. Immunitätsf. u. Expt. Ther.*, 1, Orig., 16 (1913), No. 5-6, pp. 491-503).—An antiserum for paratyphoid B and Gärtner bacilli may be produced if a mixture of these organisms is injected into rabbits. The precipitating reagents so produced act specifically with an extract made from the flesh of animals dying from meat poisoning, and with an extract of a mixture of the paratyphoid B and Gärtner bacilli. Boiled meat extracts give positive but less definite results. The best results are obtained with acetone-sodium chlorid extracts of the meat. The complement fixation reaction is deemed of no value for the direct determination of either of the two-named organisms in meat. A marked increase in hemolysin for sheep corpuscles (not for man, bovines, or guinea pigs) is noted as a result of the treatment with paratyphoid B and Gärtner bacilli.

Suprarenal glands and toxi-infections, A. MARIE (*Ztschr. Immunitätsf. u. Expt. Ther.*, 1, Orig., 17 (1913), No. 4, pp. 420-431).—The results show that natural or synthetic adrenalin will neutralize tetanus antitoxin in vitro, but when in the presence of substances which can be easily oxidized, like hemoglobin, the neutralization is somewhat inhibited. The suprarenal glands, whether in the form of an emulsion made from the powder, or a glycerin extract, have no neutralizing effect upon the toxins. The extract also destroys the neutralizing power of adrenalin in vitro. The alkaloid of the suprarenal glands also neutralizes diphtheria antitoxin, but none of the neutralizing powers was observed in vivo.

About the action of formaldehyde and salicylic acid on the formation of botulinus toxins, R. H. SALTET and J. ZEEHANDELAAR (*Pharm. Weekbl.*, 48 (1911), No. 50, pp. 1337-1340; *abs. in Centbl. Bakt. [etc.]*, 1. Abt., Ref., 55 (1912), No. 8, p. 229).—Alkaline bouillon cultures of *Bacillus botulinus* were given subcutaneously to guinea pigs with lethal results. When, however, the culture medium was treated with formaldehyde 1:20,000, or with sodium salicylate 1:2,500, and then injected, the animals remained alive.

The experimental production of pernicious anemia in rabbits, H. M. ADLER (*Jour. Med. Research*, 28 (1913), No. 1, pp. 199-226).—Fat in the form of olive oil or cotton-seed oil was found to be toxic to rabbits, if fed in sufficiently large quantities. The toxicity of cotton-seed or olive oil depended upon its content of unsaturated fatty acid. The more unsaturated the fats fed, the greater the toxic effect. Long continued daily feeding of nontoxic doses of oil produced blood crises resembling pernicious anemia, as well as extreme emaciation. Long continued feeding with nontoxic doses of quinin protected rabbits against the effects of fat intoxication, probably because of an effect upon the lymphoid tissue. The anemia thus produced is probably due to a destruction of red cells in the blood vessels of the abdominal organs rather than to a direct effect upon the bone marrow. This effect, being at the periphery in respect to the blood-forming organs, acts as a stimulant to the bone marrow and, as a result, high red blood counts are encountered. The hemolytic substance, being a fat, is not capable of true solution in the body fluid, and is therefore present in the body in the form of more or less finely divided colloidal particles.

"The hemolytic effect is not a uniformly diffused one, but is dependent upon the meeting of a particle of hemolytic fat with a red cell. The degree of injury to the individual cell depends upon the size and number of particles acting upon it. The anemia is, therefore, not one uniformly affecting the red blood cells. The red cells show all possible variations from well-colored and normally formed individuals to extreme achromia, etc. The manifestation of the toxicity

of fat is due to the summation of individual reactions between body cells and effective particles."

Contributions to the diagnosis of anthrax by the Ascoli precipitation method, T. OSCANDER (*Beiträge zur Diagnose des Milzbrandes mittels der Präzipitationsmethode nach Ascoli. Inaug. Diss., Tierärztl. Hochschule, Stuttgart, 1912; abs. in Centbl. Bakt. [etc.], 1. Abt., Ref., 55 (1912), No. 6, pp. 164, 165*).—In these experiments artificially infected guinea pigs and rabbits, and the organs from naturally infected animals which died from anthrax or were slaughtered were used. In addition, the organs of a pig found to be affected with anthrax after slaughter were examined.

The reaction is considered specific for anthrax. It is obtained instantly with extracts made from the spleen, heart, liver, kidney, and the small intestines, but was sluggish with extracts made from the stomach or large intestines. In only one case, that of the pig mentioned above, were negative results obtained.

The various methods of preparing the extract, i. e., from fresh or putrefied material by boiling or with the aid of chloroform, had no effect upon the outcome of the reaction. Extracts prepared from the lungs or muscles had a peculiar opalescence. The conservation of the pathologic material with alcohol, glycerin, and formaldehyde, and then drying at 120° C. did not seem to affect the reaction. With extracts of organs which were buried for 32 days a positive reaction was obtained even when milk of lime or petroleum was poured over the cadaver.

For carrying out the test a fresh and highly potent serum is deemed always necessary.

About the fluctuations of the agglutination titer in glanders, I. K. PAVLOVICH (*K Voprosu ob Agglutinatsii pri Sapië u Loshadei. Inaug. Diss., Vet. Inst. Kharkof, 1912, pp. 128; abs. in Centbl. Bakt. [etc.], 1. Abt., Ref., 55 (1912), No. 16, pp. 487, 488*).—The agglutinations obtained with the same serum but with various strains of the glanders bacillus were very different. The organism cultivated rapidly on an artificial medium showed the strongest agglutination. For preparing the emulsion used in the test, the most efficient agent seemed to be Konev's antiglanders vaccine. This preparation is not very virulent and consequently is of less danger to the investigator using it. Its titer also remains very constant. The emulsion, which was kept in a flask wrapped up in a few pieces of dark paper, did not vary within 3 months' time. As the emulsion is very dense, it clouds the tests, and when judging macroscopically it shows a titer lower than really exists.

In the examination of samples of blood which were taken from diseased horses at rest, and sound horses which were immunized with killed glanders bacilli, i. e., those which were still affected with glanders or had gone through the cycle of the disease, no variation in the titer was noted for several days. The titer of the blood from horses whose organisms contained no living virus did not vary when the animals were driven hard, or following the subcutaneous introduction of arecolin, caffeine, spirits of camphor, or oil of turpentine. Horses harboring living virus were affected by the above-named factors. A blood with a high agglutination titer did not always give a positive complement fixation reaction.

The tests do not verify the findings of other authors that the agglutination titer of the blood of glandered horses rises directly after infection and then falls again, as an increase in the titer was noted only with those horses which were convalescing. The criteria set down by Schütz and Miessner are deemed liable to lead one into error.

Immunizing against glanders, DE BLIECK and BUBBERMANN (*Abs. in Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 26, pp. 470, 471).—Farase yielded fair results while those obtained with heated cultures of glanders bacilli (*malleus-vaccin*) were entirely unsatisfactory. With the latter toxin the disease was increased in extent, one of the two horses treated dying six weeks after the injection and the other being destroyed on account of being very cachectic. A control animal died eight weeks postinfection. Five horses were treated with farase, four with the powdered preparation, and one with the liquid product. On autopsy it was found that none of the animals absolutely withstood the infection, but with only one exception all animals showed a partial immunity.

The canine piroplasmoses of Europe and Africa, A. LAVERAN and NATTAN-LAEBRIER (*Ann. Inst. Pasteur*, 27 (1913), No. 9, pp. 701-717, figs. 5).—Of seven dogs which were inoculated with the African virus after having been immunized with the French virus six succumbed to piroplasmosis. Two dogs inoculated with the French virus after having been immunized with the African virus suffered a light infection which terminated in recovery. The authors conclude that the African piroplasm, if not a separate species, is at least a variety distinct from the piroplasm occurring in dogs in France.

The culture of Babesia (Piroplasma) canis in vitro, J. G. THOMSON and H. B. FANTHAM (*Ann. Trop. Med. and Par.*, 7 (1913), No. 4, pp. 621-632, pl. 1, figs. 5).—"We have succeeded in cultivating *B. canis* in two out of four attempts, following the method of Bass, using blood and glucose, and incubating at 37° C. In one of these cultures, starting with heart blood containing corpuscles infected with one, two, or, exceptionally, four piroplasmata, we succeeded in obtaining a maximum of 32 merozoites in a corpuscle.

"Various types of Babesia were seen in these cultures, namely, pyriform, ameboid, rounded, and oval parasites. Division of rounded forms was observed, following the method of gemmation with chromatinic forking. There was evidence, in stained specimens, of direct binary fission. Hemolysis occurred in all the culture tubes. A puppy was successfully inoculated from a 41 hours' culture and succumbed to piroplasmosis on the fifth day. *B. canis* is not so easily cultivated by Bass's method as the malarial parasites of man."

On the cultivation of the malarial parasites and of piroplasms (Piroplasma canis) in vitro, H. ZIEMANN (*Arch. Schiffs u. Tropen Hyg.*, 17 (1913), No. 11, pp. 361-391, pls. 2, figs. 3).—The author reports upon his successful cultivation of *P. canis*, and gives a bibliography of 21 titles.

On the multiplication of Piroplasma canis in vitro, KNUTH and RICHTERS (*Berlin. Tierärztl. Wchnschr.*, 29 (1913), No. 12, pp. 211, 212; *abs. in Rev. Gén. Méd. Vét.*, 21 (1913), No. 248, p. 462).—The authors report having succeeded in cultivating *P. canis* and here describe the method employed, which is a modification of the Bass method of cultivating the malarial organisms. The best results were obtained with a mixture of equal parts of the defibrinated blood of a mildly infected dog and of a 2 per cent glucose solution, kept at room temperature.

About the formation of an acute anaphylaxis from acid-fast bacteria and from the neutral fat of the tubercle bacillus, E. LESCHKE (*Ztschr. Immunitätsf. u. Expt. Ther.*, I, Orig., 16 (1913), No. 5-6, pp. 619-626).—The results show that by treating acid-fast pathogenic and nonpathogenic organisms with normal serum, it is possible to produce an acute lethal poison. The toxin can also be produced from neutral fats and from the fat of the tubercle bacillus (*tuberculonastin*) by treatment with normal serum.

Notes on the biology of the tubercle bacillus, T. SMITH (*Jour. Med. Research*, 28 (1913), No. 1, pp. 91-110).—"Tubercle bacilli of both human and

bovine type, when kept in fully developed cultures at 40 to 50° F., may remain infectious to guinea pigs for from 7 to 19 months. The number of bacilli surviving in such cultures is relatively small. Many tubercle bacilli from easily cultivated strains which fail to multiply on fresh culture media will multiply in guinea pigs. In one of the experiments one-fifteenth hundredth of the mass which failed to grow on glycerin agar was still capable of producing generalized tuberculosis.

"Of the 2 strains tested side by side, the bovine was more resistant than the human strain. This may be in part accounted for by the fact that the human type produces much more acid in 5 per cent glycerin bouillon than the bovine type after 2 to 4 weeks of growth. It may also be due to a greater inherent resistance of the bovine type. In all experimental studies bearing on the behavior and fate of tubercle bacilli in the animal body, the character of the culture must be taken into account and its history should be known.

Do bovine tubercle bacilli occur in the sputum of tubercular human subjects? E. WÜRM LIN (*Kommen im Sputum von Phthisikern bovine Tuberkelbazillen vor?* Inaug. Diss., Tierärztl. Hochsch. Dresden, 1911, pp. 72; *abs. in Centbl. Bakt. [etc.]*, 1. Abt., Ref., 53 (1912), No. 20, p. 616).—In this investigation 44 strains of bacteria were isolated from the sputum of 24 human subjects; and 30 of these were examined. Guinea pigs were injected with 0.01 gm. of the pure cultures, and in 18 cases the guinea pigs remained sound. In 12 instances, however, the tubercle bacilli were more or less strongly virulent, and 9 of the strains produced a low grade of pulmonary and glandular tuberculosis. As a result of the tests 27 strains were pronounced to be of the human type, but the author was not able to state whether the remaining 3 strains were of the human or bovine type, consequently the problem stated in the title is unanswered.

About the growth and virulence of the causative organisms of fowl tuberculosis, W. CARL (*Arch. Path. Anat. u. Physiol. [Virchow]*, 207 (1912), No. 1, pp. 140–148; *abs. in Centbl. Bakt. [etc.]*, 1. Abt., Ref., 53 (1912), No. 20, p. 622).—Among a number of strains of tubercle bacilli, one showed a very dry growth on glycerin agar, and in this respect resembled the human type of bacillus. The characteristics were maintained after growing for 2 years. Inoculating the material produced an increase in virulency. Two rabbits treated with the original material died from generalized tuberculosis 8 days postinfection, the one with miliary tuberculosis of all organs. In contrast to this one guinea pig succumbed to a local tuberculosis, and another became generally tubercular after 158 days. A guinea pig treated with the material from the latter animal died in 136 days. A third generation produced an infection only of the regional lymphatic glands. A fowl fed with the raw material did not become sick. Intraperitoneal injections into 4 chickens resulted in typical fowl tuberculosis.

The tuberculin tests for tuberculosis in cattle, E. T. HALLMAN (*Michigan Sta. Spec. Bul.* 62, pp. 3–8).—This bulletin, which is written in popular style, discusses the factors which led up to the use of tuberculin for diagnosing tuberculosis, the preparation of tuberculin, arranging the animals for tuberculin testing, making the test, and interpreting the results of the subcutaneous thermal test. In addition the intradermal and ophthalmic tests are described.

Extracts from the state live stock sanitary laws are included.

New experiments in connection with the vaccination of cattle against tuberculosis, A. CALMETTE and C. GUÉRIN (*Ann. Inst. Pasteur*, 27 (1913), No. 2, pp. 162–169; *abs. in Jour. Compar. Path. and Ther.*, 26 (1913), No. 1, pp. 88–90).—The experiments reported deal with the excretion of tubercle bacilli

with the bile, and the retention of tubercle bacilli in the lymphatic glands of vaccinated animals. In a previous communication (E. S. R., 21, p. 683) it was shown that cattle which have been hyperimmunized by intravenous treatment with large doses (up to 200 mg.) of the bovine type of bacillus, which were cultivated successively on media containing ox bile, eliminated tubercle bacilli with their excreta. The same elimination was noted with tubercular cattle.

Thinking that possibly some of the tubercle bacilli were eliminated by way of the bile duct, the authors conducted experiments with 2 heifers having artificial permanent biliary fistula. These animals were inoculated with tubercle bacilli and the bile was withdrawn several times during the days following the injections. The first heifer received 4 intravenous injections of 10 mg. each of the bovine tubercle bacilli. The bile was then injected into 260 guinea pigs, but only 12 were found tubercular. Some guinea pigs also received injections of the feces and 2 of them became tubercular. The heifer was killed after about 4 months' time, or 2 days after the last injection of tubercle bacilli was given, and on autopsy was found to be in very good condition, not a single tuberculous focus being found after a very careful examination. After the first inoculation no tubercle bacilli were eliminated with the bile, and probably the power of elimination was established only after a certain state of tolerance was reached. "This retention of bacilli after the first inoculation is observed in healthy cattle inoculated with a dose of bovine tubercle bacilli sufficiently large to determine an acute and rapidly fatal tuberculosis. The authors have shown that bacilli are not eliminated during the febrile period of the disease, but that bacilli are present in the excrement from the commencement of the febrile phase up to the time of death."

The second heifer was given 3 mg. of virulent bovine tubercle bacilli intravenously, and a number of guinea pigs were inoculated with bile as in the preceding case. "The animal's temperature remained normal until the sixteenth day, when there was a sudden rise. There was fever until the twenty-eighth day, when the heifer died. All the guinea pigs were killed 2 months later, and not one of the 78 inoculated during the first 19 days was found to be tuberculous. Of the 31 inoculated subsequently 15 were found to be diseased. There can therefore be no doubt that during the febrile period bacilli are eliminated with the bile in large numbers. The authors think that their experiments prove that cattle that are affected with tuberculosis, whether open or not, or that have been vaccinated with attenuated or human bacilli, are capable of eliminating by the hepato-intestinal tract a larger or smaller number of tubercle bacilli which, according to their origin or degree of virulence, may be a source of danger to healthy people compelled to live under conditions which make it impossible for them to protect themselves against contamination."

As to the retention of tubercle bacilli in the lymphatic glands, it is pointed out that on a previous occasion (E. S. R., 20, p. 877) sound laboratory animals which had been rendered immune would not react, in the way of forming lesions, to an injection of virulent bacilli, nor would they react toward tuberculin, but when slaughtered some 16 to 18 months later, tubercle bacilli could be noted in the bronchial and mediastinal glands. This was proved by the guinea pig inoculation test.

This tolerance which the animals had acquired toward virulent bacilli was, according to the authors, due to the power which the animals had acquired of slowly eliminating the organisms from their systems, being unable to destroy them by the phagocytic and similar processes. The authors are also under

the impression that the power of tolerance might eventually be lost and that the elimination would then be complete. Experiments were accordingly made to determine the period of retention of the bacilli used for the test inoculation. The bacilli were subcultivated for a long period of time on glycerinized ox bile. Eight heifers which did not react toward the tuberculin test were used in the experiments. "Seven of them were killed 1, 2, 3, 4, 8, 12, and 18 months, respectively, after the test inoculation. At the post-mortem of each the bronchial glands were removed, triturated in their entirety, and injected subcutaneously into 12 guinea pigs. The latter were killed 2 months later. It was found that while none of the vaccinated heifers showed any lesions of tuberculosis at the post-mortem, every one of the guinea pigs inoculated was tuberculous. It was thus proved that a vaccinated animal might carry the virulent bacilli used for the test inoculation in its glands for 18 months after the test inoculation without their producing any lesions, although their continued virulence could be proved.

"The eighth heifer was tested with tuberculin 18 months after the test inoculation and did not react, although she no doubt harbored virulent bacilli in her glands as did the 7 that were killed. A second inoculation of 3 mg. of virulent bovine bacilli was given, but there was no elevation of temperature, and 3 months later the animal had every appearance of being in perfect health. The authors conclude that their experiments indicate that when animals are vaccinated with attenuated bacilli of the bovine type and are then subjected to a test inoculation, they do not develop any evidence of tuberculosis, but they retain virulent bacilli in their glands for periods extending into months. A number of the bacilli are passed out gradually with the excreta, as proved by guinea pig inoculations."

The vaccination of bovines against tuberculosis with bacilli of bovine origin possesses great advantages, but it is necessary to have an attenuated strain of which considerable doses can be given to bovines with ease, and which are not capable of producing lesions. The strain possessed by the authors is supposed to fulfill these requirements. It is avirulent for the ox, monkey, and guinea pigs, and confers a lasting resistance on bovines when given intravenously, but the duration of the immunity has not been established.

The hog cholera question, J. PEKAR (*Berlin. Tierärztl. Wehnschr.*, 29 (1913), No. 26, pp. 467-469).—A polemic in regard to priority and a restatement of the facts about septic endometritis and abortion present in hog cholera. The author believes that classical hog cholera, swine plague, and septicemia can be produced in pigs of all ages by simply feeding them in uterine secretion obtained from hogs affected with hog cholera, swine plague, etc. The condition produced is accompanied by an endometritis. Methods for treating the above are included.

What the agricultural experiment station hog serum laboratory is doing for California hog raisers, C. M. HARING (*Univ. Cal. Jour. Agr.*, 1 (1913), No. 1, pp. 8-13, figs. 3).—This paper gives an account of the work being carried on in the preparation and distribution of antihog cholera serum in California.

About pyobacillosis in pigs and serum treatment for the same, O. STENSTRÖM (*Svensk Vet. Tidskr.*, 17 (1912), No. 9, pp. 293-297; *abs. in Berlin. Tierärztl. Wehnschr.*, 29 (1913), No. 26, p. 471).—In an epizootic in which a great many pigs died five shoats on autopsy were found to have a pleuropneumonia, and from parts of the lungs, etc., the *Bacillus pyogenes* could be isolated. Of 60 pigs, 2 to 4 weeks old, treated with 2.5 cc. of *B. pyogenes* serum (Jensen), none died, while 2 animals kept as controls succumbed. The author concludes that the serum when used in large doses (15 cc.) has curative properties.

Epizootic encephalomyelitis in the horse, J. M. QUEVEDO (*Rev. Zootéc.*, 4 (1912), No. 39, pp. 163, 164; *abs. in Vet. Rec.*, 25 (1913), No. 1283, p. 487).—The author reports studies of an epizootic affection among horses caused by the feeding of moldy corn, which has resulted in the loss of numerous animals during the past two years. Injections of cultures of *Aspergillus maydis* into the rabbit, goat, and calf produced symptoms and lesions similar to those observed in the horse.

Some aspects of mange in horses, A. W. N. PILLERS (*Vet. Rec.*, 26 (1913), No. 1326, pp. 356-362, pls. 2).—A summarized account which deals with the subject under the headings of (1) the position of the mange mites in nature and their synonymy; (2) the characteristics of the various genera; (3) a rough outline of their life histories; (4) their vitality; (5) the degree of parasitism; (6) seasonal occurrence; (7) parts affected; (8) diagnosis; and (9) principles of treatment.

A new means of transmitting the fowl nematode, Heterakis perspicillum, J. W. SCOTT (*Science, n. ser.*, 38 (1913), No. 984, pp. 672, 673).—In feeding experiments conducted at the Kansas Experiment Station, the author has found that this nematode may be transmitted to young chicks by a dung earthworm, probably *Helodrilus parvus*, which is found in horse manure. Three chicks to which were fed a total of 78, 64, and 53 worms, respectively, between July 17 and 29, were killed on September 5, and 20 adult nematodes were found in the first, 6 in the second, and 2 in the third. Eight chicks used as checks were found to be free from the worms. Thus it appears that *Helodrilus* may in some way serve as an intermediate host for this nematode, but it remains to be determined whether the earthworm is a true intermediate host, or if the eggs of *Heterakis* simply cling to the slimy surface of the earthworm and are transmitted in this way.

RURAL ENGINEERING.

The selection and installation of a small pumping plant for irrigation, B. A. ETCHEVERRY (*Engin. and Contract.*, 40 (1913), No. 19, pp. 522-527).—The author discusses as interdependent factors upon which the proper selection of a pumping plant depends (1) the source of water supply, (2) capacity of plant and period of operation, (3) kind of pump, (4) class of engine or driving power, (5) first cost, (6) fuel cost, and (7) the cost of fixed charges and attendance.

Several tables of data are given showing capacities and efficiencies of different types of pumps and pumping plants, the power required to operate pumps, and the costs of pumping with different kinds of power at different lifts. It is shown that the cost per acre of pumping is much larger for a small area than for a large area, but it does not vary materially with the period of operation. In some cases a plant moderately large operated for a shorter period will cost less per acre than a smaller plant operated a longer period, due to the lower fuel cost with the larger and more efficient plant and the decreased cost of attendance for the shorter period of operation, which overbalance the larger fixed charges.

Some of the advantages of underground pumped water as compared to water obtained from the gravity irrigation system are stated as follows: The underground supply is more reliable and is not likely to be deficient before the end of the irrigation season. The irrigator is independent and controls his own water supply and is prepared to irrigate his crop at the best time. Underground water is also free from the seeds of weeds.

It is stated that there is a limit beyond which it is not economically feasible to pump. For small pumping plants and small areas it is well not to exceed 200 ft., but for larger plants lifts of 400 ft. may be economically feasible.

About irrigation of cultivated soils, KRÜGER (*Mitt. Ökonom. Gesell. Sachsen, 1912-13, pp. 71-113, figs. 26*).—This is a review of the operation and experimental results obtained from several methods of irrigation of cultivated soils, in which the spray system is favored. Several types of spray irrigation systems are described.

Irrigation of the Ica Valley, C. W. SUTTON (*Min. Fomento, Bol. Cuerpo Ingen. Minas Perú, 1913, No. 79, pp. 198, pls. 13*).—This publication presents the results of preliminary hydraulic studies in this valley, reports on the soil and climate, and gives considerable cost data on the design, construction, and operation of the irrigation system.

Irrigation by lateral percolation, M. RINGELMANN (*Jour. Agr. Prat., n. ser., 26 (1913), No. 30, pp. 110-112, figs. 3*).—Ditch subirrigation as practiced in parts of France, Spain, Egypt, Hawaii, and the United States is described. Attention is called to the large amounts of water used and lost in irrigating sugar cane, cotton, and grain by this method, it being stated that from 40 to 50 per cent is lost by seepage and evaporation.

Irrigation and water power laws of the State of Nebraska in force July 17, 1913 ([*Lincoln, Nebr.*]: *State Board Irrig., 1913, pp. 79*).—These laws include (1) general provisions concerning irrigation water power, (2) provisions concerning the State Board of Irrigation, Highways, and Drainage, (3) the construction and operation of irrigation works, and (4) irrigation districts.

Irrigation laws [of New Mexico] (*Santa Fe, N. Mex., 1913, pp. 32*).—Provisions of the constitution and laws of the State of New Mexico are given relating to the incorporating and government of irrigation companies and water users associations.

Irrigation laws of Wyoming in effect September 1, 1913 (*Laramie, Wyo.*: *State Engin., 1913, pp. 81*).—The text of these laws is given.

[Subsoil drainage for preventing malaria], C. STRICKLAND (*Agr. Bul. Fed. Malay States, 2 (1913), No. 2, pp. 36-42*).—The author advocates subsoil drainage by tile purely as an antimalarial measure and considers this a safe and sure method of eradicating the malaria mosquito. As an economic phase of this work he suggests that only those spots be so drained which have been scientifically established as breeding places of the malaria mosquito.

Economies of highway location; formulas and methods employed in locating roads (*Engin. and Contract., 40 (1913), No. 18, pp. 478-483, figs. 17*).—An abstract of a paper read before the International Road Congress by E. Masik presents a study of the economies of road location from a thoroughly European view point, considering general direction, alignment, grades, methods of locating the center line, longitudinal and cross sections, curves, and the calculation of maximum permissible speeds of motor cars on curves.

Action of calcium chlorid on roads, F. R. NEWMAN (*Jour. Phys. Chem., 17 (1913), No. 8, pp. 703-706*).—From experiments made to determine the action of calcium chlorid on roads the following general conclusions are drawn:

The usefulness of calcium chlorid depends upon the presence of free calcium chlorid in the soil. Very little calcium chlorid is absorbed by the soil and consequently the salt can be washed out readily. The time during which it remains effective in laying dust depends on the amount of rain and on the readiness with which the water drains off, so that there is no basis for the claim that 2 treatments with calcium chlorid will keep a road in good condition all summer. On the other hand, it does not wash out of a road so rapidly as appearances might indicate.

Earthwork haul and overhaul, J. C. L. FISH (*New York and London, 1913, pp. XIV+165, pls. 3, figs. 50*).—Part 1 of this book deals with the computation of earthwork haul and overhaul and with the use of the mass diagram in planning distribution. Part 2 deals with the economic distribution of material along the profile by means of the mass diagram.

Some experiments with mortars and concrete mixed with asphaltic oils.—Some further tests of oil-mixed concrete, A. TAYLOR and T. SANBORN (*Proc. Amer. Soc. Civ. Engin., 39 (1913), No. 3, pp. 335-363, fig. 1; abs. in Concrete-Cement Age, 3 (1913), No. 1, p. 27*).—Tests of oil-mixed concrete using western oils yielded somewhat different results from those obtained in previous experiments by Page (*E. S. R., 28, p. 85*). The conclusions drawn from these tests are as follows:

(1) Oil-mixed concrete containing 5, 10, or 15 per cent of oil, by weight of cement, is more permeable under pressures from 20 to 60 lbs. per square inch than concrete without incorporated oil, and oil-mixed mortar containing 10 per cent of oil is more permeable than plain mortar under pressures of 10 and 20 lbs. per square inch. (2) Oil-mixed mortars containing oil up to 25 per cent show slightly less absorption of water than plain mortar, except that with the most viscous oils the mortar becomes more absorptive, and absorption is not an index of the permeability. The absorption decreases with the increase in the quality of oil. (3) The tensile strength of oil-mixed mortar is decreased considerably below that of plain mortar, and decreases with the increase in the quantity of oil. (4) The compressive strength of oil-mixed mortars follows lines similar to those of the tensile strength, but with a greater decrease in strength with the quantity of oil. (5) The strength decreases with the viscosity of the oils, and with the most viscous oils it requires considerably more water to keep a mixture at normal consistency than is required in the fluid oil mixtures. (6) The relative decrease in strength with the increase in the quantity of oil in mortars is less in 50 days than in 28 days.

Concrete on farms, J. WILSON (*Jour. Dept. Agr. Victoria, 11 (1913), No. 9, pp. 570-573, figs. 3*).—This article illustrates and briefly describes machines for making concrete blocks and fence posts and describes the construction of concrete block silos.

[Information regarding concrete farm structures] (*Concrete-Cement Age, 3 (1913), No. 1, pp. 36-39, figs. 7*).—A collection of articles which illustrates and describes the construction of concrete dipping vats for hogs and sheep, small concrete ice houses, sanitary floors in dairy barns, sanitary floors for poultry, sheep, and hog houses, and a concrete cooling vat.

A treatise on the inspection of concrete construction, J. COCHRAN (*Chicago, 1913, pp. XV+595, figs. 26*).—It is the purpose of this work to set forth in detail the principal points upon which an inspector of concrete construction should be informed. The instructions are said to apply to building construction and to practically any type of reinforced concrete construction. The subject matter is presented under chapters dealing respectively with the inspection of hydraulic cement, sand, stone, and miscellaneous concrete materials; proportioning and mixing concrete; forms, molds, centering, and falsework; steel reinforcement; concreting; surface finishes for concrete work; waterproofing for concrete work; concrete sidewalk, curb, and pavement construction; concrete products; and molding and driving concrete piles.

The warning is given to use judgment in applying these suggestions, and not to use them in opposition to specifications.

Farm gas engines, C. F. HIRSHFELD and T. C. ULBRICHT (*New York and London, 1913, pp. VII+239, figs. 188*).—This book is intended primarily to serve

as a guide when contemplating the purchase of an internal combustion engine for farm use. The theory underlying the operation of such engines is discussed only to the extent necessary to enable one to appreciate the conditions which must be met by any successful engine. The greater part of the book is devoted to a discussion of the weak and strong points in the various designs, to the features which give long and useful life and those which tend to cause early failure, and to the characteristics which best adapt different types to different uses. The subject matter is presented under the following chapters: The power problem; fuels; the internal combustion engine; the mechanical construction of the engine; principles of operation; indicator diagrams; power and gas engines; the cooling system; the valve system; comparison of two-stroke and four-stroke operation; carbureters; electric ignition apparatus; the governing systems; lubrication; desirable and undesirable features of construction; muffling and mufflers; power, price, and speed; and types of farm engines.

Drive belts, their use and care, K. KROHNE (*Mitt. Deut. Landw. Gesell.*, 28 (1913), No. 15, pp. 225-228, figs. 7).—This article reviews much experimental work with drive belts, which indicates that various kinds of work, requiring various speeds and various amounts of power, require varying widths of belt and pulley and diameters of pulley, with varying arrangements of pulley axle distances for highest power transmission. The importance is emphasized of obtaining the proper arc of contact, especially in case of high speed drive, for which purpose it is suggested that "the distance between pulley axles should be the difference between pulley diameters, multiplied by 2.5." A set of curves is given for determining the proper width of belt for agricultural work when the speed and diameter of the smaller pulley are given. It is generally concluded that the largest belt wheels possible should be chosen and that on the whole with increasing speed belt drive becomes more satisfactory.

The following gear ratios are suggested under the conditions named: One to 10 with horizontal pull by the lower part of the belt; 1 to 8 when the belt drives obliquely downward and 1 to 7 when the belt drives obliquely upward, the axle distance being normal and the lower part of the belt pulling; 1 to 6 when the upper part of the belt pulls, the axle distance is diminished, or the drive runs more obliquely than 45° ; and from 1 to 5 to 1 to 4 maximum when there are no tension-regulating devices used. The pulley width, it is stated, should be the computed belt width plus 10 per cent plus 10 mm.

Application of electric drive in greenhouses (*Elect. World*, 62 (1913), No. 17, pp. 841-843, figs. 7).—This article deals with the use of electricity in greenhouses, particularly describing the extensive use of both alternating and direct current motors in a greenhouse near Chicago for operating refrigerating apparatus, fertilizer unloaders and pumps, soil mixers, etc. The electrical energy for this plant is supplied in part by a private generating plant, which also supplies heat, and in part by a public service company.

The mechanical preparation of cereals for seed and the influence on quantity and quality of the yield, H. WACKER (*Landw. Hefte*, 1913, No. 21, pp. 59, pl. 1, figs. 18).—This publication describes and discusses various threshing, cleaning, and grading machines of the latest types. It is noted that these machines aid in increasing the yields of cereals by making it possible to select the best seed according to absolute weight, specific weight, volume weight, size, and form, and to cull out the weed seeds.

Centrifugal cream separators, H. TÖDT (*English Patent* 15,946, July 10, 1913; *abs. in Jour. Soc. Chem. Indus.*, 32 (1913), No. 20, p. 987).—"To prevent the formation of froth in the skim milk discharged from the tubes in the head of the centrifugal drum, a disk is attached to the top of this head, having passages which form continuations of the tubes for the skim milk, the passages

leading to a peripheral recess on the disk into which the skim milk is conducted. Thence it is withdrawn by means of a scoop-like tube dipping into the recess but fixed on the stationary part of the apparatus; this tube is provided with a nonreturn valve."

Farm ice houses, B. S. PICKETT (*Mass. Crop Rpt.*, 26 (1913), No. 5, pp. 38-45, figs. 4).—This article deals with types of ice storage houses, including ice pits, ice stacks, makeshift ice houses, and modern well-built ice houses. The importance of good drainage, ventilation, and insulation is emphasized, dead air, wood, and paper being considered the most effective insulating materials. A modern well-built ice house, holding from 30 to 50 tons of ice, of solid construction, properly drained, and neat in appearance is said to cost from \$50 to \$125 according as the farmer supplies or hires his own labor and material.

The silo—how to make it permanent (*Brick and Clay Rec.*, 43 (1913), No. 8, pp. 780-788, figs. 17).—This article notes the essential considerations for a first-class silo, analyzes and gives data for the design, and illustrates and describes the construction of reinforced burned clay block silos.

A combined silo and water tank (*Cement Era*, 11 (1913), No. 11, pp. 34, 35, fig. 1).—The design and construction of this reinforced concrete structure is described and diagrammatically illustrated. The silo proper is of 186 tons capacity, 14 ft. in diameter, and 48 ft. 6 in. high. The tank on top is 9 ft. high, 14 ft. in diameter, and has a capacity of 10,360 gal.

The pneumatic water system, J. H. BEATTIE (*Gas Rev.*, 6 (1913), No. 9, pp. 46, 48, 50, figs. 4).—A simple explanation of the principles involved and of the proper methods of connecting up the various types of pneumatic water systems is given to prevent the common difficulties met with, due largely to the improper application of principles. It is stated that the pneumatic water system when properly installed and operated should give as good service as any isolated system, but that proper design and first-class workmanship can not be urged too strongly.

A mechanically cleaned Berkefeld filter, GRIMM (*Mitt. K. Landesanst. Wasserhyg. Berlin-Dahlem*, 1913, No. 17, pp. 40-60, figs. 2).—This article describes an improved Berkefeld filter, which is mechanically cleaned by means of the agitating effect of water and air pressure on a cleaning medium of anthracite grit, and is sterilized by using hot steam in place of air and water pressure.

The results of 172 tests of this apparatus are reported in which 1-hour filter periods were immediately followed by 10-minute cleaning periods. Both filtering and cleaning were done under 3.5 atmospheres pressure. The apparatus was sterilized once a day with steam under atmospheric pressure, this operation taking 30 minutes. Water from the Spree River was used which contained a large number of bacteria and was also very turbid, resulting in a rapid clogging of the filter.

The results of these tests lead to the conclusion that until the filter cylinders break a practically bacteria-free filtrate may be obtained and that the mechanical cleaning of all the filters in 10 minutes is feasible and reestablishes the original filtering effect.

Design of Imhoff sewage plants, L. C. FRANK and F. FRIES (*Engin. Rec.*, 69 (1913), Nos. 17, pp. 452, 453, fig. 1; 18, pp. 501, 502, figs. 3; 19, pp. 519, 521, figs. 2).—In this series of 3 articles is summed up the 7 years' experience of the Emscher River Board in Germany in the design of Imhoff settling tanks. Part 1 reviews some fundamental considerations, and gives suggestions relating to the selection of preliminary screens and proportioning of grit chambers; part 2 makes suggestions relating to the length and cross section of the settling compartment, velocity of flow, detention period, and scum boards and baffles;

and part 3 discusses the proper size for the sludge storage compartment of tanks, depth as a factor in sludge digestion, pumping sludge, and drying beds.

Regulating the climate of the house, P. M. RILEY (*Country Life Amer.*, 25 (1913), No. 1, pp. 61, 62, 84, figs. 6).—The author points out that most homes are so nearly devoid of humidity during the winter as to be injurious not only to furniture, etc., but to the health of the occupants. He emphasizes the importance of maintaining a relative humidity of from 50 to 60 per cent as long as artificial heat is used in the house, and describes apparatus for regulating it.

Agricultural drafting, C. B. HOWE (*New York and London*, 1913, pp. VIII+63, figs. 78).—The purpose of this book is to assist the agricultural student to a knowledge of the principles of mechanical drawing and their practical application to agricultural engineering.

RURAL ECONOMICS.
